SIR.—The *BRITISH MEDICAL JOURNAL* of January 9th contains a series of papers on abdominal surgery of the greatest interest, papers which invite more comment than one could reasonably ask you to give space for. Both Mr. Sinclair White and Mr. Billington make valuable remarks on Murphy's method of treating acute perforative peritonitis. I believe that the description of this by Dr. F. G. Le Conte in the *Annals of Surgery*, 1906, vol. i, p. 230, has had on the whole a good influence on the results of surgeons in general, chiefly on those of surgeons who had not previously kept the vessels full by frequent small enemata of hot water, who had also not kept their patients on the left side according to the plan first published by Lockwood, while they had douched out the peritoneal cavity, sewed up their wounds, except small openings for drainage tubes, and had also given their patients stimulants and milk by the mouth. But I suspect that the Murphy dicta have also done harm. I think Mr. Sinclair White has put his finger on one spot when he points out that many of our worst cases are not in a condition to stand even "the rapid elimination" of "a gangrenous appendix." Indeed, my experience goes to show that a gangrenous appendix is almost harmless as soon as the cavity in which it lies is made and kept absolutely wide open to the external air, provided especially if it is itself open—that is, if it has perforated. Further, while I agree that the pelvis should be drained suprapubically, that is not enough. The right flank and kidney region should be drained in many really severe cases. Further, my experience confirms that of both Mr. White and Mr. Billington that frequently repeated moderate-sized enemata of warm water are often preferable to continuous irrigation. My results have not been improved by substituting the latter for the former, and neither of them does away with the occasional necessity for intravenous injection of neutral saline solution. This should be given through the saphenous vein, because it is easily found and comparatively large—points of the greatest importance when an almost collapsed patient has to be revived in a hurry. Fowler's semi-sitting position, while excellent in suitable cases, is more than some patients can stand, but they bear the bed raised high at the head, and generally also the lateral decubitus very well.

I should like to see the whole subject of the operative treatment of severe cases of acute septic peritonitis secondary to perforations, etc., carefully treated by some surgeon of extensive experience, good operative skill (we all appear to possess that—a surgeon who cannot remove all the large intestine with its mesocola and accessory glands and have the patient comfortably back in bed in ten minutes appears to be rare), and open mind, one who would give us, without selection, his cases related with a brevity corresponding to that of human life, but with sufficient detail to be of real use, and above all a surgeon who would refrain from trying to settle our doubts by knocking us dizzy with a couple of figures, one minutely small and the other very heavy, tied to an adjective and a noun or two, such as "diffuse," "suppuration," "general," and "peritonitis."

Mr. Bernard Dawson, in his exceedingly valuable paper, has repeated a small error which originated elsewhere. He writes that "Murray in 1905 first suggested appendicostomy for protracted constipation, and later in the same year Keetley performed the operation." Mr. Murray's letter suggesting a temporary appendicostomy in cases of constipation appeared in the *BRITISH MEDICAL JOURNAL*, 1905, vol. i, p. 1299. This led me in the issue of the following week to publish my first case of appendicostomy for constipation, which had been performed three months before, and, of course, demonstrated freely to post-graduates and colleagues, but which was scarcely ripe for publication. I gave the continuation of this case in the *BRITISH MEDICAL JOURNAL* for October 7th, 1905. It was in this latter paper that the possible usefulness of appendicostomy in the treatment of typhoid fever was also first suggested by me. Of that subject I have written at much greater length elsewhere. I am sorry to make these corrections, because Mr. Bernard Dawson's paper is exceptionally accurate. And, above all, it gives many valuable references, generally in such a manner as to spare trouble.—I am, etc.,

London, Jan. 10th.

C. B. KEETLEY.

APPENDICOSTOMY.

SIR,—The increasing advocacy of appendicostomy during the last six years, following the suggestion of Keetley in 1894, and the performance of it for colitis by Weir eight years later, culminating in Mr. Keetley's recent paper before the Surgical Section of the Royal Society of Medicine and those in recent numbers of the *BRITISH MEDICAL JOURNAL*, will serve to encourage its more frequent use and to define its indications. I wish, however, to criticize its performance during operations for *intussusception* "to prevent recurrence," which is given by Keetley, Moynihan, and others as one of the indications for appendicostomy.

About a month before Mr. Keetley's first recorded appendicostomy for intussusception I performed the operation on a collapsed child 9 months old, with the supposed two-fold object of preventing recurrence and of immediate injection of nutriment (March 5th, 1905). It was found that peptonized milk injected through the appendix was immediately expelled from the rectum, and the child died.

My next appendicostomy after reducing an intussusception was on January 11th, 1906, the child being 6 months old; but, instead of preventing recurrence, the child came back three months later with a return of the intussusception, for which I operated successfully a second time, and exhibited the patient before the Bristol Medico-Chirurgical Society on May 10th, 1906.

This is the only recurrence of an intussusception which I have had. I am therefore inclined to regard the anchoring of the appendix as predisposing to recurrence rather than to its prevention, by interfering with the mobility of the caecum, which is naturally very free in the young child, and by making a fixed point below the common site of the commencement of an ileo-caecal intussusception, which is in the ileum, an inch or two above the ileo-caecal valve. If this be a correct deduction from my own experience, the importance of arresting injudicious appendicostomy, with the idea of preventing recurrence of intussusception, is obvious.

I have performed appendicostomy in seven cases with great satisfaction excepting in the above instance; am favourably impressed with it in certain cases of intestinal obstruction; and had performed it twice before the first recorded case of Mr. Keetley for that condition (December 21st, 1906), namely, November 16th, 1905, on a patient of Dr. Kendall; and November 23rd, 1905, on a patient of Dr. R. H. Walter.—I am, etc.,

Clifton, Bristol, Jan. 11th.

T. CARWARDINE.

IS APPENDICITIS A MODERN DISEASE?

SIR,—I was very interested in Mr. Raven's solution of the cause of death of King Herod Agrippa. There are a few points which may lead to a not unprofitable discussion associated with the letter. I venture to point out the "worm" pathology of disease was so common that there is hardly need to explain Herod's worm as either a worm-like appendix, trichinosis, or nematode, etc. Curiously

enough, the account given by Josephus of the death of Herod (*Great does mention worms*, "and a putrefaction of his privy member, that produced worms" (Wars, I, xxxiii, 5). This Herod also had a colon trouble, according to Josephus. The Herods are rather an interesting family medically. One is inclined to wonder whether the author of the Acts confused the accounts of the death of the first Agrippa and his grandfather.—I am, etc.,

Ilminster, Dec. 5th.

W. H. MAIDELOW.

SYPHILITIC LEUCODERMA AND THE PIGMENTARY SYPHILIDE.

SIR,—As Sir Jonathan Hutchinson, in his illustrated communication on this subject in the *JOURNAL* of January 9th, still does not appear to grasp how well this condition is known in England, and considers that Mr. Shillito's account has the only coloured illustration, I feel constrained to draw the attention of himself and your readers to the fact that in the third edition of my textbook,¹ in the coloured illustration of the principal syphilides, Fig. 11 illustrates accurately, and I think adequately, the "pigmentary syphilide," as I prefer to call it, from one of my own cases. In the text, a page and a half are devoted to its description and literature,² and two of my own cases are briefly referred to as proof of its occasional early appearance.

The fact is that though, as I state, it is "a rather rare condition," it is not very rare, and I have seen a good many cases, including a few males, and I should have thought that it was well known to every dermatologist and syphilographer in all countries. I can quite understand that Sir Jonathan Hutchinson has long ceased to refer to textbooks, and I make no personal complaint; but as his authority is so great as a syphilographer, I think it is desirable to point out an oversight, which might otherwise be accepted as a correct statement.—I am, etc.,

London, W., Jan. 9th.

H. RADCLIFFE CROCKER.

P.S.—I consider that it is the ringed pigmentation, rather than the white central portion, which is the abnormality.

SIR,—In the face of the implication contained in a statement made by Sir Jonathan Hutchinson in the course of his recent paper,³ namely:

As I have said, were it not for this article I do not think that I should incline to make an apology to my friends your two correspondents. I find exceedingly little evidence that any of the brief statements in systematic works were written from personal observation,

I should like to be allowed to make a few remarks. In the first place, I must disclaim any desire for apology, especially from Sir Jonathan Hutchinson, whose valuable contributions to medical knowledge are known to and admired by us all. Personally I regret that he should have made any mention of such a thing in a matter of this kind.

As one of the two correspondents mentioned by him, and speaking for myself, I would repeat that in my book on *The Differential Diagnosis of Syphilitic and Non-Syphilitic Affections of the Skin* in 1904, I considered the subject of the pigmentary syphilide of the neck of such importance that I devoted practically a page to the condition (page 200), and also incidentally referred to it on page 47.

Over ten years ago, when I had the pleasure of working at the Lock Hospital, Dean Street, with the late Mr. Edward Cottrell, then in charge of the female department there, I collected 193 consecutive cases of syphilis in women, of which two were old syphilis, two five and six years old syphilis respectively, and the remainder quite early (with a primary sore still present) or recent (not older than two years). These cases were examined by me, and although the investigation of this series was carried out for another purpose altogether, I find, on looking through my tabulated notes, that the pigmentary syphilide of the neck was present in 17 cases:

Pigmentary syphilide	10
Marked	2
Slight	4
Apparently of some standing	1

17

¹ I believe it was described in the first edition in 1898.

² This goes back to Hardy in 1858, who first described the condition.

³ *BRITISH MEDICAL JOURNAL*, January 9th, 1909, p. 86, col. i.

With the exception of 2 cases, all the others (15) came into the category of early (so-called secondary) syphilis. In one patient, with a marked pigmentary syphilide of the neck, a pigmentary syphilide of the genito-crural folds was also present. As the cases of this series were not examined from the point of view of the pigmentary syphilide specially, the percentage is, of course, lower than it should be.

I have also seen the pigmentary syphilide of the neck in men, but it is very rare. In two such cases the young men presented some of the secondary sexual characters of the female. In another case the lower part of the abdominal region was also similarly affected; this man I demonstrated to the students at University College Hospital.

Among the examples of the pigmentary syphilide of the neck shown by me at the Polyclinic, one patient was a man presenting the condition in a marked manner.

I need say no more in this place, as I am preparing a paper on the subject embodying some seventeen years' observations.—I am, etc.,

London, W., Jan. 11th.

GEORGE PERNET, M.D.

THE APPLICATION OF MENDELIAN RULES TO HUMAN INHERITANCE.

SIR,—I am quite unable to follow Dr. Drinkwater's procedure, and until we have a common standard of what is and what is not to be called Mendelism, it is quite impossible to proceed further.

I make 368 offspring of eight blind individuals in Mr. Nettleship's pedigree. Others may count up to 376; it all depends on the inclusion of certain doubtful cases. Taking 368 we have 131 abnormals and 237 normals. 131 in 368 is not 50 per cent., which is what the simple Mendelian theory demands.

Dr. Drinkwater, as I understand him from his letter in the BRITISH MEDICAL JOURNAL, would in a case like this of offspring of an abnormal:

count one normal and two abnormals, not counting the tail of the offspring because there are no abnormals among them. I should count, as I believe Mendel would have done, four normals and two abnormals. Dr. Drinkwater may not mean this, but it is the only interpretation I can put on his words "if we stop at and include the last abnormal." In a letter of explanation he has courteously sent to me he further tells me that he has excluded the offspring of first or second marriages of abnormals, when there are no abnormals in the offspring of these marriages. I presume also that if an abnormal marry once and have no abnormal offspring, such marriages have also been disregarded. He tells us that one normal may be recessive and another normal dominant to the abnormal. Since he stops at the last abnormal in a family, I presume we must also suppose the dominance of the abnormal to change at this point. But why stop here? Why should not the dominance change more than once during the mating? The moment we admit "personal" dominance as opposed to "character" dominance, and allow personal dominance to vary from mating to mating and even during a single mating, we are, as Dr. Drinkwater shows, able to obtain a desired percentage. But is this Mendelism, or a new theory of heredity, or a confusion of all the issues upon which the application of Mendelian rules to man depends?—I am, etc.,

University College, London, Jan. 7th.

KARL PEARSON.

VINCENT'S ANGINA.

SIR,—In the JOURNAL of January 9th (p. 87) Dr. Nash expresses some scepticism respecting the pathogenicity of Vincent's bacillus. I wish to support that attitude. Routine daily examination of throat and ear specimens has afforded the following evidence:

1. That fusiform bacilli (Vincent's bacillus) and spirochaetes are present in the majority of throat smears (acute and chronic).
2. That they are also present in 80 per cent. of normal throats.

3. That they are of frequent occurrence in discharges from the nose and its accessory sinuses, the antro-tympanic cavity and brain abscesses.¹
4. That they are especially numerous in conditions attended by decomposition and fetor (chronic states).

The cases of acute angina were always associated with either streptococci, pneumococci, diplococci (Gram —), or staphylococci, and it is to these that the exciting cause is to be attributed rather than the *Bacillus fusiformis*.—I am, etc.,

V. H. WYATT WINGRAVE, M.D.

Pathologist, Central London Throat and Ear Hospital.

January 9th.

THE HOME TREATMENT OF SCARLET FEVER.

SIR,—My recent paper under the above heading² has brought me a considerable amount of correspondence, and I trust you will allow me space for one or two further observations in illustration and expansion of the same subject.

I have at present seven cases of scarlet fever under my care in our girls' village home at Barksideside. These cases are in seven different cottages. The girls affected have been mingling freely with others throughout the village since they were attacked. The medical officer of health has watched their progress with the keenest interest. I have suggested to the local secretary of the British Medical Association that he should invite the members and other medical men of the district to call at the village and see these cases any Tuesday, Thursday, or Saturday afternoon (when I am in attendance). I have also invited another medical officer of health to visit us with his class of students (from the London Hospital) for the purpose of inspection. The girls attacked not only mingle freely with the other children in the cottages, but they attend church and school, where they come in contact with any of the other 1,300 children in the village. The ages of the patients range from 8 to 16 years. The cottages in which they live are widely apart from one another. In every instance the symptoms have been clear from the beginning, and later every one of them is having well-marked peeling. Dates and comments are embodied in the subjoined table:

Date of Attack.	Case Notes.	Condition as to Peeling.
November 2nd, 1903 ...	Severe throat and rash	Heavy.
November 5th, 1903 ...	Slight at first, then well marked	Freely.
November 5th, 1908 ...	Throat and rash severe	Heavy.
November 10th, 1903 ...	Well marked	Freely.
November 10th, 1903 ...	Ditto	Ditto.
November 12th, 1903 ...	Ditto	Ditto.
November 13th, 1908 ...	Ditto	Ditto.

Formerly I was much troubled with doubtful cases. Now, under the treatment which I advocate, these give me no anxiety whatever. On the slightest suspicion the children are kept in bed for from two to four days and rubbed each morning and evening with eucalyptus oil. In all confirmed cases I have had the children rubbed once daily until the tenth day.

I have had the assurance throughout that the milk was supplied from farms certificated free from any infectious disease, but I certainly should have no hesitation in taking the milk from a farm where children or others were affected with scarlet fever, provided only that my treatment was fully and absolutely carried out there.

I would suggest that some districts be selected where scarlet fever is threatening to become epidemic, and that all the medical men unite under, say, the medical officer of health to adopt for a test the plans I have set forth. In this trial I would strongly urge that a fully competent staff of careful nurses be selected and supplied for the carrying out of the treatment. For a fair trial the cases under each nurse ought not to be too numerous.

I recommend that when the home treatment of scarlet fever is adopted, the isolation hospital now used for scarlet

¹ Royal Society of Medicine, June, 1908, Clinical and Pathological Aural Discharges.

² BRITISH MEDICAL JOURNAL, October 31st, 1908.

fever should be continued; but only for the purpose of taking in, for a short time, children failing in health. To find out these there must be frequent and careful inspection, with particular inquiries regarding home life when necessary; but, above all, exact weighing of the child from time to time: for before any other sign becomes visible this alone will show that the child is failing. Even among the thousands of boarded-out children from Dr. Barnardo's Homes this is regularly carried out, and the weight recorded. This first indication of failing health demands inquiry and treatment, for it is at this early stage, before any physical signs exist, that the insidious onset of tuberculous trouble is so easily detected and combated. A short period of kind and careful nursing, with changed surroundings, speedily reinvigorates the child. The expense incurred is little in comparison to the benefits that flow from such treatment. Then, for those who are more seriously indisposed, arrangements should be made for the children to be sent to a seaside convalescent home for children. By such kindly forethought and treatment can we alone hope to invigorate thousands of our future men and women—the fathers and mothers of the future. This, too, would do much to draw the sting from the trying position of the poor.

If my method of treatment for scarlet fever were generally adopted, the effects would be alike important and far-reaching, quite apart from the merely professional aspect of the subject. For instance, a friend of mine, who is an owner of some weekly property in London, lately told me that during the past five years sporadic outbreaks of scarlet fever had occurred in his houses on six or seven occasions. In each instance, he said, a bill of costs amounting to several pounds had been incurred for disinfection and cleaning. Such an expense to property owners would be wholly unnecessary if all scarlet fever cases were dealt with by my system. I never order even the washing of a blanket or a night-dress for merely disinfecting purposes after scarlet fever, far less the disinfection of a room. Wherever a patient has been properly treated he ceases to be a centre of infection, and there is no infective risk remaining. Any child may sleep in the bed which the patient has been occupying. In this matter alone there would be a very large saving to the public purse without any risk to the public health. That is only one of many directions in which the marked benefit of the treatment would be manifested.

I should like to be permitted to add a word of warning on the subject of measles. Since my paper was written a measles epidemic appeared in our receiving home, where sixty children were in residence. The epidemic was limited to the first infection—that is, to cases occurring within twelve to sixteen days after the first appearance. Yet I cannot speak with the same confidence in regard to measles as with regard to scarlet fever. I should like to emphasize this, because several correspondents have written to me as if I had recommended my line of treatment being pursued with equal confidence in cases of measles as in cases of scarlet fever.—I am, etc.,

ROBERT MILNE, M.D.

London, E., Dec. 12th. Medical Officer, Dr. Barnardo's Homes.

MEDICAL MEN AND CONTAGIOUS DISEASES.

SIR,—A printed sheet about "insurance benefits for medical men only" has been received by me. I see from it that 920 claims have been paid on account of accidents and certain diseases. I find that 27.5 per cent. of the claims were due to "septicaemia." I admit that medical men are exceptionally exposed to septic infections, but, nevertheless, it appears to me to be out of all proportion to what it ought to be. And yet, I am not surprised. Within a period of fifteen years I have known men to examine fresh wounds with unwashed fingers, and also to handle cases of diphtheria, scarlet fever, and even small-pox, without even deeming it necessary to wash their hands afterwards, until reminded of it by me or the nurse. Such gross carelessness or ignorance of medical and surgical cleanliness is, I am glad to say, the rare exception and not the rule. But it does exist.—I am, etc.,

M.D., D.P.H.

DIARRHOEA OR INFECTIVE ENTERITIS.

SIR,—In the article in the *Times* (Friday, December 25th) on "Immunization against illness," a brief summary

is given of the mortality from "diseases chiefly affecting children." The deaths from whooping-cough are stated to be 11,909, and that "there were also 29,759 deaths from diarrhoea or infective enteritis, of which total 27,494 were in children under 5 years of age."

When studying the etiology and symptoms of whooping-cough I came to a conclusion regarding one symptom, which I thought it well to state clearly in my lecture at the hospital in Great Ormond Street as follows:

There is one symptom to which I would direct your attention—the symptom of diarrhoea, usually occurring in hot weather, and not infrequently diagnosed as the special disease, infantile diarrhoea. It is a very serious and often fatal symptom. The only observation to be made respecting it is that the laryngeal and pulmonary symptoms usually subside when that of diarrhoea arises.

The question of interest is whether some of the high mortality attributed to "infantile diarrhoea" may not be due to whooping-cough. That was the conclusion I came to after several years' careful observation of this singular infectious malady.—I am, etc.,

ROBERT LEE.

Pwllheli, Dec. 26th, 1908.

THE COLD BATH TREATMENT OF TYPHOID.

SIR,—A few years ago very extensive and reliable statistics showed that the death-rate of enteric fever was undoubtedly reduced under the cold bath treatment by about 7 per cent. as compared with other methods. The same results appeared in England, Germany, the United States, and Australia, wherever the Brand system was employed in its essentials. As Osler said, "From 6 to 8 per cent. more lives were saved." In fact, the normal death-rate seemed to be from 6 to 10 per cent., instead of the 17 per cent. which had lasted in England from the days of Murchison.

More recently there has been substituted for the troublesome cold bath system in some places a method of cold sponging or cold packs. I wish to ask if there are any reliable statistics showing the mortality under this method.

Does cold sponging save the 7 lives in each 100, or do we drop back under it to the old 17 per cent.? Of course baths are not possible for all persons and in all places, and sponging is much less trouble, but have we any ground for believing in its power to replace the bath? No doubt it reduces temperature and relieves symptoms, as, indeed, antipyretic drugs did, but are those 7 lives in each 100 patients saved by it or are they lost? What are the actual facts? Are there any statistics which justify us in using it when baths are possible? If there are no statistics, I for one will gladly subscribe towards the cost of collecting them.—I am, etc.,

X.

EUCALINE AS A LOCAL RELAXANT.

SIR,—The action of eucaine in relaxing the sphincter ani in an operation for haemorrhoids as related by Surgeon-Major Porter in the *JOURNAL* of January 2nd (p. 17), is especially interesting to me, as I was the first publicly to draw the attention of the profession to the relaxing power of its congener, cocaine, on the rigid os in parturition (vide *Transactions of the Obstetrical Society of London*, vol. xxxvi, 1895). It will perhaps also be remembered by some, that since the reading of my paper on this question at the Edinburgh meeting, I have pleaded in the *JOURNAL* that a trial of the drug should, as suggested by Dr. Alexander Duke, be made in purely gynaecological work; but I have not so far noticed that the suggestion has been adopted. As eucaine is generally considered less toxic than cocaine, why not try the former in other cases in which relaxation of spasm is wanted—as is spasm of the glottis—another suggestion of Dr. Duke's? I have not used eucaine in rigid os, as I am quite satisfied with the action of cocaine in such cases; but it might perhaps be of service in spasm of other parts as well as in that of the sphincter ani.—I am, etc.,

JOSEPH FARRAR, M.D.

Gainsborough, Jan. 2nd.

THE FLEA AS A CARRIER OF PLAGUE.

SIR,—Has not Sir Havelock Charles, who writes on this subject in the *BRITISH MEDICAL JOURNAL* of January 9th, made a mistake in reference to the covering of the Ark?

The only covering the Ark had was gold. The coverings mentioned in his letter were of the tabernacle, and it does not appear that the coverings of the tabernacle were carried with the Ark in the incidents referred to.—I am, etc.,
January 9th. A. A. M.

SIR,—I was very interested in Sir Havelock Charles's letter, for I have long looked upon the pestilence of the Scriptures as the modern plague and, like him, thought that the Hebrew word probably covered both mice and rats. But a reverend gentleman who understands Hebrew wrote me a long letter in 1905 demonstrating that there was no warranty for it meaning anything beyond mice, and particularly field mice. Does the Hebrew word really represent both rodents? If so, the history, page 1247, vol. ii, 1900, is at once carried several centuries further back. The suggestion of the badger skins is ingenious.—I am, etc.,

Birkenhead, Jan. 11th.

GEO. S. STANFIELD.

THE RHEUMATIC ORIGIN OF SEROUS INFLAMMATIONS.

SIR,—I have read with great interest Dr. Eustace Smith's article on the above subject,¹ as well as Dr. Duker's remarks upon it.²

Dr. Duker speaks of gout and rheumatism, thus marking the identity of those troubles—a point which I have long insisted on.

I have also recorded a case of peritonitis, more chronic than that of Dr. Eustace Smith, in which salicylates cured at once, after many other things had been tried.³ I have not the least doubt that his case did get well because it was treated with salicylates; for years I have never treated appendicitis or peritonitis with anything else, and until the inflammation has gone on to suppuration, or unless it is due to tubercle, I always expect a speedy cure.

His case of endocarditis reminds me of a case of phthisis I saw a good many years ago in a patient who belonged to a very gouty family. As he was somewhat pulled down by night sweats, I gave some phosphoric acid and strychnine, and this was followed by a sharp rise of temperature with signs of arthritis in the left shoulder and the appearance of a systolic murmur at the apex of the heart. The patient died a year or two later of his lung disease, and meanwhile I saw him several times, and the murmur never disappeared. Since then I have believed that endocarditis may be produced by drugs—at least, in the gouty and rheumatic—and have investigated the point in other cases mentioned in my book.⁴

I have also cured many cases of intestinal catarrh in the same way that Dr. Duker did. The slighter and more chronic conditions of this kind are often related to cold, as Dr. Eustace Smith's case of peritonitis appeared to be, and may sometimes be completely cured by the use of warmer clothing over the abdomen and legs.

In the case of the bronchial mucous membranes, as I have pointed out in your columns,⁵ it is best to use alkali and not salicylate, but with other fibrous tissues either solvent may be used, salicylates acting best in acute cases with high temperature, alkalies best in less acute cases, where the acidity of the urine is not much raised. The minor conditions of flatulence and colic are often due to similar causes (urate precipitation by acids or cold, and lead colic is, I believe, due to urate of lead) and can be cured by solvents in exactly the same way. Similar troubles in the stomach are often called "gastralgia," "catarrh," or "gastritis," and the same in the uterus or ovaries, the prostate and bladder, or, in fact, in any fibrous tissue in the body; it is only after solvents of uric acid have been properly given and have failed that we need look for other causes of local trouble—for example, septic conditions, tubercle, or new growths. The conditions that are due to urate retention are generally worst in the hours of physiological retention (evening and night), and, as my friend, Mr. J. Guthbertson Walker of Rochdale, recently pointed out to me, the highest temperatures in appendicitis have been recorded exactly in the hours of greatest uric acid retention (9 to 10 p.m.).

¹ BRITISH MEDICAL JOURNAL, November 28th, 1908, p. 1601.

² Ibid, December 12th, 1908, p. 1778.

³ Uric Acid, edition vii, p. 425.

⁴ Loc. cit., p. 753.

⁵ BRITISH MEDICAL JOURNAL, May 9th, 1908, p. 1100.

I should be inclined to say from my experience that the cases in which appendicitis originates in mechanical conditions are small in number compared with those in which it originates in gout or rheumatism (uric acid retention), though the former may precipitate the latter.—I am, etc.,

London, W.

ALEXANDER HARRIS.

MEDICAL INSPECTION AND SCHOOL CLINICS.

SIR,—Your leading article on January 9th calls for some comments from members of the class frequently referred to in that article and in the reports which it discusses, but, as far as I can judge, very poorly represented in the deliberations of the committees that have taken up this inquiry—namely, the general practitioners, unattached to any hospital, provident or Poor-law dispensary, who, I venture to think, constitute the bulk of the profession. With the possible exception of Dr. Beaton I find no one either on the subcommittee appointed by the London Education Committee, or among the witnesses invited to give evidence before the same, who might be said to represent the class to whom I refer.

You, Sir, in your article presumably take up the cudgels on behalf of the general practitioner, but I venture to think that your conclusions go further towards undermining and ultimately shattering his present status, livelihood, and prospects than does even the report referred to.

The conclusion to which I wish specially to object is that "the State is committed to the policy of . . . giving or procuring proper care for sick or defective children of school age" (p. 103). I ask where and when has such a principle ever been conceded? The furthest we have gone in this direction will be gathered from the findings of the subcommittee; but, Sir, they do not go so far as you do, and the general public may see fit to differ from their comparatively moderate conclusions. When you tell us that all children of school age who are sick or defective must be cared for by the State we rub our eyes.

We are willing to admit (and that is a great advance, or concession if you will) that such children as the State may compel to attend its schools shall be brought there in such a condition of body and mind that the instruction gratuitously provided may be used to the best advantage. Compulsion, in other words, has discovered obligations such as were not dreamt of by the early advocates of free education; but privileges entail similar obligations, and whether these obligations are primarily binding on the compelling State (viewed as a whole) or on the privileged portion of the State (the parents and guardians) in particular is, I think, still open to discussion.

But even if the former of the two alternatives be admitted, this is not going so far as does your article when it refers to all "of school age" as being the care of the State. If age is to be the criterion, then it must be shown that school age is the period of life beyond all others in which non State-aided effort has proved inadequate, and in which State-aided effort is likely to prove most advantageous. What, then, about the clause in the report: "An education authority . . . has no power over a child during the first three critical years of its life, when the harm is usually done." Clearly, if age is the criterion, it would be more rational to attempt treatment during this "critical period," and such, no doubt, will be the next suggestion.

Space does not allow a discussion into the vistas of possibilities that the principle, as enunciated by you, opens up, but let me indicate a few; and here I avoid exaggeration, for I consider the man who exaggerates not so much a knave or a fool, as the limping advocate of a losing cause. A child comes to school insufficiently clad—it is, therefore, "a defective child" within the meaning of the principle; the State must therefore provide boots, socks, and underclothing; insufficiently fed, therefore the State must feed it (we have advanced a few steps in this direction); any illness, however caused, however trivial or serious, however protracted, must be the care of the State if the child is "of school age." This, Sir, and no less, is what can be legitimately deduced from the principle as laid down by you. We shrink from the prospect.

Some very substantial qualifications are demanded, or we, in general practice, shall feel that we have been betrayed by an ill-considered pronouncement. We shall be

¹ BRITISH MEDICAL JOURNAL, 1908, vol. ii, p. 1874.

constrained to say that we looked for confidence but behold confession, for firmness but behold a cry (of despair).—I am, etc.,

Nottingham, Jan. 19th.

A. CHRISTIE REID, M.D.

THE TREATMENT OF SCHOOL CHILDREN.

SIR,—Your correspondent, "Country Doctor" (BRITISH MEDICAL JOURNAL, December 5th, p. 1721), need not worry himself, for very shortly, as far as I can see, he and all his fellows will be as extinct as the dodo, or else in receipt of that reward the State so graciously provides for worn-out workers. For what do we see?

I suppose that my practice is, on the whole, rather above the average. I manage to net about £400 a year; of this about £50 goes for taxes and insurance, and nearly £200 for rent and education of my children, who must be sent away to boarding school, as there is no school available in the neighbourhood.

Now, nearly half my income comes from Poor-law, vaccination, and sanitary appointments. We have already got the vaccination fees docked; we are threatened with a drastic alteration in the Poor-law appointments and the loss of our sanitary work. School officers have just been appointed, and we are advised that school clinics must follow, and that they will be in the hands of the school officer, who will also in most cases be the medical officer of health, who must be in theory a whole-time man, but who, under the new arrangements, appears likely to spread himself over all the paying parts of our work, leaving us the task of making a living by going to help uneducated midwives with impecunious patients in circumstances of difficult midwifery, for whom no one will be financially responsible further than 3s. 6d.—I am, etc.,

December 15th.

ANOTHER COUNTRY PRACTITIONER.

OLD AGE PENSION MEDICAL CERTIFICATES.

SIR,—If Dr. Pearson Taylor looks at the Instructions to Pension Officers, 26, paragraph 113, he will find that the pension officer can, by visiting the person, relieve the medical man of responsibility, a duty which might very properly be left to him to discharge till provision is made to remunerate us for our labour and loss of time.—I am, etc.,

Cahir, Jan. 10th.

J. POWER, M.B.

SIR,—Dr. H. P. Taylor asks in the JOURNAL of January 9th to whom are we to look for payment for signing certificates to the effect that the claimants mentioned on the certificates are permanently incapacitated through bodily infirmity from attending at the post-office in person? I say without any hesitation that the pension officer of the district should provide the money for this purpose. It is he who brings the certificates with the request that they should be signed, and it is he, therefore, who employs the doctor. But he is a representative of the State, and, to quote from another part of the JOURNAL, the experience of the medical profession in Germany should be quite sufficient to teach the profession in this country—if, indeed, it still needs the lesson—that the State will not go out of its way to deal generously with doctors.

We do not ask for generous treatment, but we do ask for fair play and justice. Therefore the correct method to adopt is to demand payment, and if no money is forthcoming to return the certificate unsigned. I wonder at the officer having the impudence to ask such a thing from any doctor. Of course, the amount of money to be paid for each certificate would be small, and would not repay one for the time spent in visiting and examining the claimant, but it is not the £ s. d. I am thinking of, but the principle underlying it. I sincerely hope that all the medical men who have to sign these certificates will get their fees, or else return the certificates unsigned. It is simply another turn of the wheel for other things to follow: our last surprise was the Notification of Births Act, and it is high time now these things were nipped in the bud, and the Government and the public generally were made to know that we want paying for our work, and that we do not consider it *infra dig.* to receive money for work.—I am, etc.,

Liverpool, Jan. 10th.

A. STANLEY PARKINSON.

SIR,—I think Dr. Taylor should have no hesitation in charging pensioners for certificates of bodily infirmity—for

this reason, that any gratuitous services will simply give rise to one more "doctor's grievance," and as such will exist for all time; whereas if the pensioner has to pay for the certificate, the grievance—if grievance there be—is his, and will probably be remedied before next January. Feelings of compassion for these poor old people should not blind us to the utter uselessness of charity; that whatever we give benefits not the recipient, but him whose duty we usurp, in this instance the State.

On the same grounds of pity, we might easily saddle ourselves, as in part we have already, with gratuitous attendance on all sick labourers, whereby we should benefit not the labouring class, but their employers; who could and would speedily cut down wages to the reduced minimum of subsistence resulting from free medical attendance.

An instructive book to read on this subject is G. B. Shaw's *Common Sense of Municipal Trading*, wherein it is shown how a little extra pay to the corporation servant provides the outside employer with cheaper labour from the other members of the family.

The plan I have followed in regard to pension certificates is that, where I know the old people personally, I fill up the certificate gratis, but with strangers and whenever it is likely that the matter will be known to others and be talked about, I have charged an ordinary visiting fee.—I am, etc.,

Bristol, Jan. 9th.

HARRY GREY.

THE STATE REGISTRATION OF NURSES.

SIR,—My absence from home has prevented me from asking before for permission to reply to a letter from Dr. J. A. Coutts, on the State registration of nurses, which appeared in the BRITISH MEDICAL JOURNAL on December 12th, 1908. After Miss Mollett's admirable reply to that letter I need only, and briefly, correct some of the inaccurate statements made by Dr. Coutts, as I feel sure he will not desire that your readers should be misinformed on this important question. Dr. Coutts, I gather, is under the impression that only the matrons of hospitals to which a medical school is attached have either the right or the capacity to form a reliable opinion on the organization or work of nurses. In his attempt to depreciate the constitution and influence of the Matrons' Council he argues as if there were but twelve hospitals in London! The fact is that the sick require equally careful and experienced nursing in upwards of 150 hospitals in the metropolis, and it is greatly to the credit of the matrons of many of these institutions that in spite of very considerable intimidation, carried on for the last twenty years, they have associated themselves together to obtain much needed reforms and improvements in the work and education of nurses. Dr. Coutts cannot deny the Matrons' Council the credit of bringing the question of State registration into the sphere of practical politics; and, considering the determined opposition of influential persons to its policy, one must conclude that it is not quite so contemptible and ineffective a body as Dr. Coutts suggests.

The Society for the State Registration of Trained Nurses only claims to represent the 2600 nurses who have, in spite of the above opposition, associated themselves for the one definite purpose of organizing trained nursing under the authority of an Act of Parliament, although nearly every organized nurses' society in the kingdom is represented by delegation upon its executive committee.

Dr. Coutts, who tells us he is a member of the Central Hospital Council for London, evidently shares the animosity of its moving spirits to independent professional co-operation on the part of trained nurses. He writes:

Now considering that there are, according to Mrs. Bedford Fenwick, 50,000 nurses who will be entitled to registration under the present bill (I have never made any such statement), the fact that only 2,000 could be induced to join the promoting society, after more than twenty years of "strenuous work," is a sure indication that there is no strong desire on the part of the nurses themselves for registration. In the course of these years, moreover, many who joined have doubtless married or given up nursing, and it is a natural inference that a large proportion of the members of the society are not engaged in the active practice of their profession.

What are the facts? The society he criticizes was founded in 1902, and has therefore been working for six

and not "upwards of twenty years." During this time it has been joined by upwards of 2,600 matrons and nurses, who with very few exceptions are unmarried and actively engaged in the practice of their profession. Nurses who have had the courage of their opinions are fully aware that as soon as our bill becomes law thousands of "the best nurses" all over the country will eagerly avail themselves of the professional privileges which it will bestow; but, as registration will not be compulsory, those who consider it injurious to their individual interests will be under no obligation to register.

Finally, Dr. Coutts scouts the idea that coercion has been employed to prevent nurses associating together for professional purposes. I would recommend him to study the papers, pamphlets, and letters of more than one of his colleagues on the Central Hospital Council, and to read up the legal cases in connexion with the Royal British Nurses' Association. Moreover, Dr. Coutts surely knows that various hospital committees who employ large numbers of nurses have for years been publicly opposing the registration movement. Yet he desires your readers to believe that those working women dependent on such committees for their professional education, and thus for their future livelihood, would actually dare to publicly support a reform which their employers publicly oppose. This is a point in nursing economics which need not be further discussed.

But this long-debated question of the registration of nurses is not one to be decided by hospital committees. It is a question affecting the safety and well-being of the community in general, and as such must be dealt with by Parliament. Within the last few years trained nurses, or women posing as such, have been convicted and hanged for murder, proved guilty of performing illegal operations and manslaughter, of extensive frauds and of numerous thefts, have been admitted into private houses on the strength of false certificates, and have over and over again, between their periods of incarceration in gaol, gained "an honest livelihood" at the bedside of the sick, women of evil character flaunt our once honoured uniform "on the street," figure in the divorce court, and frequent the pot-house. Others, ill-trained and incompetent, cause an incalculable amount of human suffering. Year by year an increasing number of such "nurses" are exploited by innumerable nurse farms, which, at enormous profit to themselves, defraud the sick public.

At last this long-suffering public is beginning to realize the disorganization which reigns supreme in the nursing world. This is proved by the widespread support given by all classes of the community to the Matrons' Council and the Society for the State Registration of Trained Nurses in their demand that, by Act of Parliament, order should be evolved out of chaos, the public protected, and the nurses of the future given systematic education, and, when certified, placed under rules of professional discipline.—I am, etc.,

ETHEL GORDON FENWICK,

Honorary Secretary, Society for the State Registration of Trained Nurses.

20, Upper Wimpole Street, W., Jan. 8th.

SIR,—In a letter in a recent issue of your JOURNAL Mr. Sydney Holland has made a statement which may be misleading to many, and one which I think, for the credit of the nursing profession, we are entitled to have corrected. He says that "a two years' London Hospital trained nurse was good enough to be chosen to nurse His Majesty." We know it is a fact that the London Hospital is accustomed to send out to serious cases of illness nurses with this amount of experience only, charging the same fees for them as are required by the nurses who have had their full three years' training. But I put a question to him. Was this nurse sent to His Majesty, after having been seven weeks in Tredegar Home, one year ten months and one week in the wards of the hospital (less, of course, holidays and days off duty), or had she had several years' experience before she was sent to nurse this important case? As Mr. Holland has made such a statement in your columns I think we are entitled to a plain answer from him.

If, as he says, the bill for the State Registration of Nurses will in no way affect the London Hospital, why agitate against it? One can scarcely put any other inter-

pretation upon such a sentence as "Our nurses would not register," than that he is posing as the autocrat of that institution. Surely this will be a matter for each individual nurse unless undue pressure is to be brought to bear upon them?—I am, etc.,

Clapton, N.E., Jan. 11th.

W. F. HADFIELD.

EPSOM COLLEGE.

SIR,—Mr. Morris, in his recent appeal for subscribers to this most excellent institution, stated that only one-eighth of the profession gave their financial support to the college—a not very creditable state of affairs. It is, however, to the concluding remarks of the letter, where he attributes the smallness of the number of subscribers "to lack of thought or to the need of being reminded," to which I would specially refer, in the hope of finding a remedy. I would suggest the institution of an Epsom College Day—say the anniversary of the foundation—for a simultaneous appeal to every member of the profession not already on the subscription list. This could be made through the local secretaries, but sent from the chief office. I would further suggest that sums as low as 5s. should be accepted, in the hope that the regulation guinea would follow in course of time.

Under this scheme no one could plead ignorance of the obligation to support an institution which is of such great benefit to the children of the less fortunate of our body, besides giving comfort to those of our colleagues who "fall by the way."—I am, etc.,

London, W., Jan. 11th.

CHAS. W. CHAPMAN.

COLLEGE REFORM AND THE HOOD.

SIR,—The latest effort made to defend the old position of the Royal Colleges in medicine has been that by Sir John Tweedy, and it was mentioned in your leader on November 28th, 1908. Such authority and support of this endeavour to counteract my original suggestion to join the colleges with the university system demands an answer. It is to be hoped it will be the last of a long series of piecemeal counter-schemes, the weakness of this one and the others being that they would only be makeshifts. No word was sounded why this new view of a united English, Scottish, and Irish college university should be formed at all, nor even why it should supersede the progress so far accomplished in the reform of the colleges during the year. So the movement would be retrograde and undo what has been done, and at best can but serve to warn the University of London of a countervailing opportunity if she were so unloyal as to refuse access to her institution. However, to join all these countries together could give no possible common ground for a university. Besides, this formation of a totally separate, unsupported, and ridiculously insufficient and unprovided-for university, jammed together out of the college system, was entirely rejected when Sir William Jenner's committee proposed the same thing in 1889. We want something better than that in England! Let London lead in this matter with her premier colleges in a substantial and statesmanlike alliance with her own university. Then, if the Scottish and Irish colleges will permit me to say so, the same thesis I have maintained for fifteen years in this cause for the English colleges may equally apply to them.

At the last annual meeting of the Royal College of Surgeons Mr. F. W. Collingwood introduced a small reduplication of the ditto when he asked that the council should grant "some more sufficient title" to the diplomates. This is the frequently discussed theme of the title of doctor, and obviously the colleges cannot grant the degree of doctor as from a university.

But I have often pointed out the "courtesy title of doctor" is quite a different thing, and it is undoubtedly very widely acquiesced in. And it stands not only on a similar application to the custom with M.B.s, but on a fairly earned basis and nearly equal curriculum in comparison with university degrees. The council can therefore legitimately be asked to recognize the "courtesy" custom of such a title, so long as no use were made of the letters M.D., nor any claim put forward to a legal right, until the above reciprocity with the University of London has been established.

At the same meeting the council demurred to grant a hood to the Fellows and Members. At the previous

meeting, when the resolution in favour of a hood was carried, I categorically traversed their reasons for refusing it. They have never satisfactorily been able to reply to this, but blindly adhere to the formula, "Is it likely the council will alter its decision in a matter once decided?"

It is a mistake to assert that no college gives a hood, for, without counting any divinity college that may, the regulations of the Royal College of Organists and the College of Preceptors do make clear reference to the wearing of their own hoods.

It would only be just, on the part of the council, to reconsider the whole matter, and to revise their misguided decision, so as to arrive at conformity with so patent an issue. The right to wear a hood is claimed by right of custom after a completed academical course, and beyond that of a mere certificate, though the degree or licence of the colleges is often acknowledged to be on a fair and legal equality with many graduates who have taken non-honours degrees. The Council of the College itself has often acknowledged this equal talent of their members with graduates from the universities. The same equality is borne out on public grounds. The colleges have been named in the London University Act as worthy of representation with the graduates upon the senate of the University of London. Similar representation has been accorded to the colleges upon the governing bodies of several provincial universities. Other public bodies, such as the General Medical Council and the Midwives Board, treat the college representatives on an equality with those of the universities. And in the eye of the law the statutory qualification of members and graduates, apart from any special or frequently varying local requirements, must be regarded as synonymous. It will be regrettable neglect of the Fellows' and Members' interests if the council refuses to supply this outward mark of equal treatment, and, if an academical dress is to be worn at all, to fail to complete by a hood the academical costume now supposed to be worn.—I am, etc.,

Bognor, Dec. 25th, 1908.

H. ELLIOT-BLAKE.

P.S.—The reform of the colleges concerns a large body of Members and graduates. I propose to print a condensed account of the reform; and if those interested will send me their address, I would intimate to them when it was ready.

THE ST. JOHN AMBULANCE ASSOCIATION AND THE MEDICAL PROFESSION.

SIR,—In the JOURNAL of October 24th, 1908, you publish a memorandum from the Chief Secretary of the St. John Ambulance Association, pointing out how much the association is indebted to the medical profession, and what awards and distinctions are conferred upon doctors who render special service in the cause of the association. As there are exceptions to every rule, so perhaps the association may be free to make what exception it thinks fit; and in my case I may be classed amongst the exceptions. For about twenty years I have served the aims of the association as honorary lecturer and as a paid examiner. When Mayor of Durham (in 1894 and 1895) I organized and arranged a large meeting of miners, holding first-aid certificates, in the Town Hall; and a service in Durham Cathedral, when a special preacher advocated the principles of the association. At the Town Hall meeting I was assisted by the Mayor of Stockton for the time being, when we endeavoured to urge the need of instruction in first aid for miners, and we initiated a subscription for an ambulance for the Durham County Hospital, which was afterwards obtained.

Within the last six years I exerted myself in moving coalowners and others to provide an ambulance shield for the county of Durham for competition amongst teams of miners in first-aid work. The shield was obtained, and the competitions have been regularly held, and ambulance work has been considerably stimulated thereby.

About this time I discovered that a medical neighbour of mine had his name enrolled in the list of distinguished ones in the annual report book of the association; this neighbour had been a lecturer and an examiner for about half the time during which I had been connected with the association. I wrote to the secretary and pointed out to him the difference in his claim as compared with mine for

any mark or distinction. The secretary, in reply, forwarded me a form to fill in, and for me to state what distinction I should like to obtain. Needless to say, the form was not filled in, nor did I ask for any distinction. I preferred to remain an exception to the general rule.

If this is the usual way in which the St. John Ambulance Association confers distinctions on those who have worked for its advancement, then I do not think others will be much encouraged; nor do I think that the association deserves so much gratuitous support from the profession.—I am, etc.,

Durham, Jan. 12th.

EDWARD JEPSON, M.D.

PAYMENT OF DOCTORS FOR HOSPITAL INQUESTS.

SIR,—At a meeting of the honorary medical staff of the Enfield Cottage Hospital held recently, it was unanimously decided to forward an appeal to the Departmental Committee appointed by the Home Secretary, "to inquire into the law relating to coroners and coroners' inquests, and into the practice in coroners' courts."

In this appeal it was pointed out how hardly the law presses upon such medical staffs in not allowing any fees to be paid them when attending inquests on patients who have died in hospital.

Reference was also made to the invariably sympathetic attitude of coroners and juries towards medical men when their attention is drawn to this injustice, and the committee was asked to recommend that the law be altered so that we should receive the usual remuneration.

If the medical staffs of all such hospitals throughout the country would act in the same way, without delay, there can be little doubt that sufficient pressure could be brought on the committee to induce them to consider this appeal favourably, and it is with this object in view that I am asking you to publish this letter.—I am, etc.,

HOWARD DISTIN, M.B.

A Member of the Honorary Medical Staff of the Enfield Cottage Hospital.

Enfield, Jan. 12th.

GRATIS PATIENTS.

SIR,—The increasing difficulties that beset medical men in their endeavours to maintain their social position and to pay their debts are more and more enhanced by the number of people who ask for, and obtain, professional assistance without paying a fee. It would be interesting to know what is our duty as a profession in this matter.

I have attended the following cases during the last week, and they have been a great tax on my energies, and a considerable expense in journeys.

M., aged 64. Enlarged prostate with retention. A gentleman much reduced in circumstances and unable to pay a fee. Several visits at a considerable distance.

F., aged 45, widow of doctor. Receives advice as a matter of course. No fee offered or asked for.

F., aged 38, daughter of retired physician; living with father. No fee offered or asked for.

F., aged 35, daughter of deceased doctor. Earning own living; much reduced in circumstances. Unable to pay fee.

F., aged 40, an Irish lady. Much reduced; trying to get work. Unable to pay.

M., a professor of languages. Illness two years' duration has reduced him to poverty. "Asked by a patient if I would kindly look after him."

I sometimes wonder whether my brother practitioners have as many of these cases on their lists as I do, or whether my reputation consists in being "a good-natured fool." Of this I am certain: "like begets like." A guinea patient will recommend guinea patients, and a no-fee patient will send their equally unprofitable friends, with the doubtful praise: "Oh, go and consult Dr. So-and-so; he is so kind; he saw me for nothing."

With regard to attending doctors' relations, I may mention that I always do all I can to persuade the doctor looking after my family to accept a fee, but usually without success. Personally I think it would be much more satisfactory to all concerned if fees were offered and accepted in the case of doctors' relatives, except where poverty made this impossible or inexpedient.—I am, etc.,

X.M.D.

Medico-Legal.

MIDWIVES AND STILLBORN CHILDREN.

THE coroner for the city of Lincoln held an inquest on January 4th on the body of a child which had been buried as stillborn and exhumed by order of the Home Office in consequence of the receipt by the police of an anonymous letter. In the course of the inquiry, medical evidence was given by two witnesses to the effect that the child was at full term, and weighed 5 lb. 13 oz. There were no external marks or bruises on the body. The right lung was in its upper part completely dilated, and its lower part was also dilated but not entirely. The condition of the left lung was of a corresponding kind. The other organs were normal and healthy. The witnesses could not declare that the child had had a complete and separate existence, but it had evidently breathed, though not for long. There was nothing in the *post-mortem* phenomena inconsistent with the statement made by another witness, not present at the birth but in the same house, to the effect that she had heard the child scream. There was no reason why it should not have lived if it had received proper attention. It probably died for lack of attention during birth or immediately afterwards, being suffocated by being allowed to lie face downwards.

The mother of the child, it was stated, might have had a motive for not wanting the child to live.

The burial authorities accepted the body for interment on the strength of two certificates. One was to the effect that it was a certificate given by a person who was a registered midwife, that she had delivered the mother of the child herself, that that the child was stillborn, and that no medical man was in attendance. The other certificate stated that the person signing it declared that the body brought for burial was the child of certain persons mentioned, that it was born on a given day, but born dead, and that the signer of the certificate was present at the birth. The midwife in question, it was shown, had applied to a medical man for a death certificate but had been refused. She admitted when examined in court that she had not been present at the birth, and did not know whether the child was stillborn, and did not now think it was. She did not know why it had died. She did not write the certificate herself, but admitted that it was written to her dictation and signed for her with her authority. As regards the second certificate, the woman signing it admitted that she had signed it under a name which was not her own, and that she had not really been present at the birth. She did not look at the child when she arrived, as she had been told by the mother to go downstairs and make a fire, and did not know really whether it was alive or dead.

The jury brought in a verdict to the effect that the child failed to live owing to want of attention at birth, and stated that the midwife should be warned as to her future conduct, and that the other woman deserved censure for not attending to the child immediately she arrived at the house.

The coroner, during the course of the inquiry, drew attention to the importance of the issues raised. The facts revealed showed how very deficient the law was in regard to stillbirths. Nothing could be easier than for some one who wished to hush up the circumstances of a birth to get a child buried without any inquiry by any qualified or responsible person as to whether it had been born alive or dead. Questions of infantile mortality were at the present time much to the fore, and it was remarkable that those in high places who had the power to alter the law did not alter it and make death-certificate requirements more rigorous. At the conference of coroners on infantile mortality it was pointed out how defective the law was in this respect, and it was clear that persons, even as ignorant as those who had appeared before the court, could get round the present provisions. In conclusion, he warned both the women involved in the case that they might have to answer for their conduct in another court.

JUDGE'S COMMENTS ON INDUSTRIAL INSURANCE METHODS.

WE learn from the *Birmingham Daily Post* of January 7th that at Tunstall County Court on January 6th, before Judge Ruess, Edward Evans sued the Universal Insurance, Loan, and Investment Company, of Leeds, for £5 18s., the amount of a policy effected by him on the life of his uncle, Joseph Boulton. In support of the claim, it was stated that the policy was taken out on June 24, 1907, that it was issued by the company named Willett, who said there would be no difficulty about the uncle's life, and that he would pay the money if the uncle died. The uncle died in November last, and the company relied for refusal to meet the claim on misstatements as to his health. The plaintiff, in his evidence, said he did not know anything about the questions in the form of proposal, and he did not fill in the answers, but merely signed the form. He admitted that his uncle suffered from bronchitis, and had been under medical treatment for three years. His honour said they had to warrant that the man was free from disease or physical defect. In other words, he had to be a perfect man, which was not often found. Bernard James, district superintendent of the defendant company at Hanley, gave evidence as to the effecting of the insurance. The company issued industrial policies to working people. The agents did not generally fill out the forms to his knowledge. He and the judge said they could not accept that statement, because in ninety cases out of a hundred it was done. William Roberts, superintendent of the company at Tunstall, admitted that a good many of the forms were filled up by the agents; and

Arthur James Willett, who effected the insurance, admitted that he filled in the answers to the questions, but said he put each question to the plaintiff and recorded his answers.

The Judge said it was the recognized business for the agent to fill in the forms. The company could not carry on their business without it. The questions on the form which they got people to sign were most unreasonable. They put the people entirely in the company's power. All they had to do when the death occurred was to find that the deceased at one time had bronchitis, and so on, and so they would escape liability. The policy in that case ought never to have been disputed. He gave judgement for the plaintiff with costs and refused leave to appeal, remarking that one of these days he would give leave to appeal, but it must be on terms. It must be on some such terms that the company paid costs on both sides.

WORKMEN'S COMPENSATION CASES.

Compulsory Operation.

IN *Falloon v. White Star Steamship Company*, which was decided by his Honour Judge Shand at the Liverpool County Court on January 5th, the applicant, a marine fireman, had sustained injury from an accident on the ss. *Celtic* in September, 1908. Since the accident he suffered from rupture to an extent which incapacitated him from following his employment, and he received compensation down to November 27th, 1908; but on that date the employers brought the matter before the court, and alleged that if the applicant submitted to a simple and not dangerous operation the man would be completely cured in about two months. As he had declined to submit to the operation, they contended that they were no longer bound to pay him anything. His Honour adjudged the case to January 5th, by which time the man might be assumed to have recovered if he underwent the operation. On January 5th it was proved that the applicant still refused to undergo the operation.

In giving judgement, his Honour said: If there had been any danger it would have been another matter; but the medical evidence is conclusive that the operation would be simple, and, with anaesthetics, attended with little or no pain, and would have enabled the applicant to resume his employment. His continued incapacity is therefore the result of his own fault, and the payment agreed upon at 16s. 8d. a week during incapacity will be terminated as from this date. In this finding I am confirmed by certain Scottish cases and by the case of *Warneck v. Moreland* in the Court of Appeal. I must close the compensation altogether, making a note that the applicant's incapacity no longer arises from the injury, but from his refusal to undergo the operation.

COMPENSATION FOR BURNS IN AN EPILEPTIC.

H. writes: A workman has an epileptic fit while at work and falls in the fire, sustaining burns which incapacitate him for several weeks. Can he claim compensation? He states that his employer knew he was subject to fits.

* * We are of opinion that this matter can be settled only by the county court judge. It is very probable that if an employer undertakes the responsibility of employing a workman who is the subject of epilepsy he might be called upon to pay compensation if this man suffered an injury "arising out of and in the course of his employment." The knowledge that the workman was an epileptic would probably not relieve the employer of his liability. The workman ought to consult his solicitor with a view to having his claim adjudged before the court.

POOR-LAW MEDICAL OFFICER AND THE COMMISSION OF THE PEACE.

"RUSTICS" writes that he is informed that he cannot be appointed a Justice of the Peace for the county, because he is one of the Poor-law medical officers of the district in which he resides. He wishes to know if this is a general rule throughout the country.

* * Before the passing of the Local Government Act, 1894, which abolished *ex officio* guardians, a Poor-law medical officer could not be appointed a Justice of the Peace, because he was *ex officio* a member of the board of guardians, but since 1894 there has been no legal obstacle to such an appointment.

LIABILITY OF HUSBAND FOR ATTENDANCE ON WIFE.

W. F. E. writes that he was called in to attend a married woman, while on a visit in his district, by her mother. Her husband was aware of this, as he visited his wife several times during her illness. Our correspondent now finds that it will be necessary for him to take steps to recover his fees. He wishes to know who is legally responsible—the mother, who called him in, or the husband.

* * The husband is legally responsible if he lives with his wife. It might be otherwise if there is a judicial separation between them. In that case the question whether he or the wife were responsible for the doctor's fees would depend on the terms of the separation. The mother is not liable, unless she gave an undertaking in writing to be responsible for payment.

Obituary.

DOUGLAS ARGYLL ROBERTSON, M.D., F.R.C.S.E.,
LL.D., F.R.S.E.,

HONORARY SURGEON-OCULIST TO H.M. THE KING IN SCOTLAND;
CONSULTING OPHTHALMIC SURGEON TO THE ROYAL
INFIRMARY OF EDINBURGH.

INTIMATION by telegraph reached Edinburgh on Tuesday, January 5th, of the death at Gondal, India, on Sunday, January 3rd, of Dr. Argyll Robertson. On retiring from practice in 1904 he made his home at Mon Plaisir, St. Aubins, Jersey, for the sake of the milder climate. On November 30th, 1903, he left Jersey for India, via Marseilles, taking with him the Prince and Princess Tarabas, the son and daughter of the Thakur of Gondal, whose acquaintance he first made when that Indian potentate was studying medicine at the University of Edinburgh some twenty years ago. The acquaintance ripened into a warm and close friendship, and Dr. and Mrs. Argyll Robertson were entrusted with the care and education of the eldest Princess after the Thakur returned to his Indian State.

Douglas Argyll Robertson (he was always known thus, though his name is entered in the Register of Fellows of the Royal College of Surgeons as Douglas Moray Cooper Lamb Argyll Robertson) was born in Edinburgh in 1837. His father was John Argyll Robertson, M.D., F.R.C.S.E., a Lecturer in Surgery in the Extra-Academical School, who devoted himself chiefly to ophthalmic surgery, was President of his college in 1848, was followed in the President's chair by James Syme, and had two brothers—Robert and William—also Fellows of the college. Thus, Douglas Argyll Robertson was not only born into a surgical connexion but was, by his father's main bent, directed to that department of surgery in which he was afterwards to become so great an authority and ornament. He was educated at the Edinburgh Institution, at Neuwied in Germany, and at the universities of Edinburgh, St. Andrews, and Berlin. He graduated M.D. St. Andrews in 1857, and became a Fellow of the Royal College of Surgeons of Edinburgh in 1862.

From the beginning of his career he devoted himself exclusively to ophthalmic surgery. From 1867 to 1870 he was Assistant Ophthalmic Surgeon to the Edinburgh Royal Infirmary, his Senior being Dr. William Walker, and in 1870 he was appointed full Ophthalmic Surgeon along with Dr. Walker, and at the latter's retirement in 1862 he was sole Surgeon till 1897, after which he was Consulting Surgeon. While, as has already been said, it was his father's influence that first directed him to ophthalmic surgery, it must be remembered that the time was ripe for the development of this branch of surgery in Edinburgh and elsewhere, inasmuch as it was the time when the founders of modern ophthalmic surgery, Bowman and

von Graefe, were at the height of their fame, and were drawing round them the younger and more brilliant members of the medical profession from all parts of Europe. Argyll Robertson visited von Graefe's clinic at Berlin. Von Graefe died, at the age of 42, in the year 1870, the year in which his admiring pupil was made full Ophthalmic Surgeon to the Edinburgh Royal Infirmary.

Acting on a hint from his friend, Dr. (now Sir) Thomas Fraser, Argyll Robertson turned his attention to the Calabar bean as an important agent in the treatment of eye conditions. The result of his studies was embodied in a paper on the Calabar Bean as a New Ophthalmic Agent, which appeared in the *Edinburgh Medical Journal* and the *London Ophthalmic Journal* in 1863. In 1869 and 1870 he published papers in the *Edinburgh Medical Journal* On Eye Symptoms in Spinal Disease, in which he directed attention to the loss of the reaction of the pupil to light, while it still continues to act

with accommodation in tabes dorsalis—a condition now generally known as the "Argyll Robertson phenomenon." In the Royal London Ophthalmic Hospital Reports for 1876 he contributed a paper on Trephining the Sclerotic: a New Operation for Glaucoma. Later, in the *Transactions of the Ophthalmological Society of the United Kingdom*, he had a paper on a Case of *Filaria Loa*, and several others.

For several years he was Lecturer on Diseases of the Eye in the University of Edinburgh. In 1886 he was elected President of the Royal College of Surgeons of Edinburgh, and in 1896 the University of Edinburgh conferred on him the honorary degree of LL.D. He was Vice-President of the Section of Ophthalmology at the British Medical Association meeting at Dublin in 1887, and also at the meeting in London in 1895, while he was President of the Section at the meeting in Edinburgh in 1898, and he had been President of the Edinburgh Branch of the British Medical Association. He was Honorary President at

the International Ophthalmic Congress in 1888 and 1899, and President of the Congress in 1894. He had been President of the Edinburgh Medico-Chirurgical Society, a President of the Ophthalmological Society of the United Kingdom, a Corresponding Fellow of the New York Academy of Medicine, an Honorary Member of the Royal Medical Society of Edinburgh, a Foreign Associate of the Society of the Practising Physicians of Prague, and an Honorary Member of the Neurological Society of New York.

For many years he was a member of the Committee of Management of the Scottish Joint Board, which grants the Triple Qualification. He was Surgeon-Oculist to Queen Victoria in Scotland, and later Surgeon-Oculist to His Majesty King Edward VII for Scotland.

Dr. Argyll Robertson was fond of the social side of life, and naturally was a member of the Aesculapian Club, the Round Table Club, the Harveian Society, and the Cap and Gown Club. On his departure from Edinburgh in

DOUGLAS ARGYLL ROBERTSON.

McGet, Edinburgh

1904, the last-named club entertained him at a farewell dinner attended by over one hundred members. In replying to the toast of his health he made one of the most delightful speeches he ever delivered. He dwelt on the value of golf to the busy professional man who knew how to make the wise and correct mixture of work and play. Of all recreations he thought it was most to be commended. It was to golf that he attributed much of his good health and much of his enjoyment of life. Some forty or fifty years ago he was one of the leading amateur golfers on the Scottish links. He won the gold medal of the Royal and Ancient Club in 1865, 1870, 1871, 1872, and 1873; and the silver cross in 1867 and 1871. He also attained distinction by winning the gold medal of the Honourable Company of Edinburgh Golfers in 1870, 1874, and 1876. Of all recreations, "commend me to golf" he was wont to say. Golf was his great recreation.

His portrait, painted by Sir George Reid, was presented to him by a number of his professional brethren before he retired. A replica of the portrait hangs in the Surgeons' Hall.

He was fond of shooting, and was a member of the Royal Archers the King's Body Guard for Scotland, where his fine and handsome physique and dignified bearing marked him out in all the public appearances of that select and splendid *corps d'élite* of Scotland. Nor were his recreations confined to golf, shooting, and archery. He was a keen fisher, was fond of travel, had been in India more than once, and once as far as Japan. At one time he was a keen and notable curler. He was a member of that old and select club, the "Coates Club," which has existed for more than two hundred years. Argyll Robertson's dictum was the time-honoured one of curling—"everything level on the ice." A good story of him is told in this relation, not that there were not also many other good stories of his recreations. On one occasion his side was short of a man. Argyll Robertson went into the tent where the beef and greens were being prepared and asked a waiter if he could "play a good stone." The waiter replied that he thought he could. On the ice he did so; he sent up a very good "stone," although it failed to reach the "pot-lid." "Put a little more mustard in it," shouted Robertson, as the waiter sent up his second "stone."

In 1882 Dr. Argyll Robertson married a daughter of Mr. W. M. Fraser, of Findrach and Tornavein, Aberdeenshire. Another daughter married the late Dr. James Foulis, and a third is the wife of Lord Robertson of the Appeal Court. Mrs. Argyll Robertson was a great favourite in Edinburgh social life, and great regret was expressed when she and her husband decided to move to Jersey in 1904. A wide and deep sympathy will be given to her in her great sorrow. There were no children.

Dr. Argyll Robertson's most intimate friend in the medical profession, if not even without that restriction, was the late Sir Thomas Grainger Stewart, whose death he felt very keenly.

We are indebted to Sir Anderson Critchett, Bart, for the following: For nearly forty years I enjoyed the friendship of "the dear old chief," as he was affectionately called by his students, and I know only too well that his loss will leave a void which no other personality can fill in the hearts of all who loved him. The handsome, intellectual head and splendid frame once seen could never be forgotten, for he was the ideal representative of well-balanced mental and physical vigour. The watchwords of his life were Courage, Duty, and Honour, and he possessed in a marked degree that old-world courtesy of manner which is too seldom to be found in this age of lustre, advertisement, and self-assertion. Those who were present at the International Ophthalmic Congress held in Edinburgh under his presidency in 1894 will recall the blended dignity and geniality with which he controlled the meetings, and the generous hospitality extended to one and all by his fair partner and himself. In more recent times he was asked to preside at meetings during similar congresses held at Utrecht and at Lucerne, and we, his colleagues, rejoiced to see him occupy that exalted position, for we felt that Great Britain could not possibly have a grander or more efficient representative. He was an exceptionally brilliant and successful operator, fertile in initiative and resource, possessing that firm yet gentle power of manipulation which begets such perfect confidence in the patient, while those who watched his skilful operations might well exclaim, in the words of his gifted countryman, "The hand of Douglas is his own." The only occasion, within my knowledge, on which he hesitated to face the surgical situation was when it became necessary to operate on his brother, the late Dr. Lockhart Robertson, for cataract, and I felt much honoured when he asked me to relieve him of the fraternal responsibility. It would be impossible to find a more perfect example of the *Mens sana in corpore sano*, for with his great intellectual powers and deep scientific knowledge he combined a love of manly sport. He was an excellent shot, he belonged to the Archers of the Royal Body Guard, and his wife's most cherished ornament was a necklace formed of the numerous gold medals he had won at golf. Although he could show unflinching firmness and force of character when the occasion demanded those qualities, he was never so happy as when in genial companionship he could throw off the fetters of professional responsibility and heartily join in the fun and frolic of the moment. He had a keen sense of humour, and I shall never forget the leonine roar of mingled appreciation and reproach with which he received my suggestion that it was far better to be an Argyll Robertson pupil than to have one. I sincerely hope that his sorrowing friends and former students may be able to provide some permanent memorial of this great and good man, either in connexion with Edinburgh University or with the Ophthalmological Society of the United Kingdom; but the splendid work which he has done

has already placed him in the ranks of the immortals, for he has left a reputation and a name which cannot die.

Not Heaven itself upon the past has power.

That which has been has been, and we have had our hour.

A former colleague writes: Up to the time when Argyll Robertson began practice as an ophthalmic surgeon in Edinburgh the newer methods of treatment of eye disease had received little attention in Scotland. The foundation of what is recognized as the modern ophthalmology was mainly the work of one man—v. Graefe. No doubt v. Graefe's great contemporaries, v. Helmholtz and Donders, contributed not a little to the scientific development of this branch of medicine. Yet it was v. Graefe who gave the lead and took the giant share in the enormous clinical advances which were made in the early part of the second half of last century. It was to v. Graefe that every one specially interested in ophthalmic surgery turned for guidance. Argyll Robertson was of the number who had the privilege of working under and of learning from the great pioneer himself. He was thus inspired with the confidence and enthusiasm in the teaching of v. Graefe which characterized all the pupils of that truly wonderful man. It was not long, indeed, before the knowledge and experience which Argyll Robertson had gained in Berlin began to bear fruit in Edinburgh. Possessed himself of the scientific spirit, he was able to make many important contributions to ophthalmology. Though not given to much writing, he maintained throughout his career a profound interest in his own subject, and, indeed, in medicine generally, and always kept himself fully abreast of the times. As a teacher he was successful in interesting his students. Teaching as he did a subject so full of complex physiological problems, he nevertheless carefully avoided puzzling them by the introduction of any hypothetical or even recondite matter. Clinically, he taught treatment and not pathology. As a practitioner he was able, both in private and in hospital, to render important service to a large *clientèle*. Argyll Robertson had many interests besides those of his own profession, which in a place like Edinburgh, where so many varied interests are represented, brought him a very wide circle of acquaintances. He was a connoisseur in art, and at one time one of the judges in the Royal Scottish Academy. As a golfer he was a well-known figure on the links at St. Andrews, and on more than one occasion carried off the various medals awarded by the Royal and Ancient Club. As a member of the Royal Bodyguard of Scotland—an archer, he was successful in different competitions. Argyll Robertson also took an interest in travel. At different times he visited America, Japan, and India. It was while on a visit to India to the Thakur of Gondal that he died. Although it is now some years since, owing to ill-health, he was obliged to sever for good his connexion with Edinburgh and take up his abode in Jersey, where frequent visits in spring had accustomed him to a more congenial climate, he left behind him many old colleagues and friends who now lament his death.

HUGH M. MONTGOMERIE, M.D. EDIN.,

SENIOR PHYSICIAN WEST CORNWALL INFIRMARY.

We regret to have to record the death of Dr. Hugh Mayer Montgomerie, of Penzance, on December 12th, 1908. For the greater part of the week he had been moving about the town as usual, and very few indeed knew of his sudden illness. He was present on the preceding Wednesday at the opening of St. John's Church House, and the same evening he attended a concert at St. John's Hall on behalf of the West Cornwall Infirmary. He had, however, contracted a chill, and exposure to the weather aggravated his condition. Dr. Symons attended him, but the case rapidly took a serious turn, angina pectoris being the cause of death.

Dr. Hugh Montgomerie was the only child of Dr. J. B. Montgomerie, an old Penzance practitioner, and was born on July 31st, 1864.

He was educated at Winchester School and Edinburgh University, where he took the degree of M.D. He also spent some time abroad, in Paris, Vienna, and Berlin, studying throat and ear diseases, in which he specialized. He practised as a physician, and among other good qualities, was esteemed for his great professional kindness

to the poor. Dr. Montgomerie joined the West Cornwall Infirmary as Honorary Physician about 1887, and was sole physician there for nineteen years. Since the rebuilding of the institution he had been senior of the medical staff. In the Thirties, Dr. Montgomerie's grandfather—after whom the present deceased spelt his name with "ie"—was Physician at the Infirmary, and since that time the family have worthily maintained their association with this good work. Dr. Montgomerie was Secretary of the Penzance Antiquarian Society for three years down to 1900, and in the following year he became its President. In 1898 he was President of the South-Western Branch of the British Medical Association. At one time "Dr. Hugh" was a devotee of bathing, and in his college days played football. His father, Dr. J. B. Montgomerie, who survives him, was President of the South-Western Branch in 1877, and he and Mrs. Montgomerie have the sincere sympathy of a large circle of friends in the loss of their only child.

The funeral took place on December 17th, 1908, at Gulval churchyard, and was very largely attended. The Mayor of Penzance and many leading residents were present. The medical profession was represented by the following: Drs. Miller, Chas. Bramwell, Kenneth Bennett, Edwards, R. Lawrey, R. D. Boase, W. R. Wilson, Basil Page, Collier, Russell Phillips, and Chetwood-Aiken (Penzance), Greenwood-Penny (Marazion), Best (St. Ives), M. R. Taylor (Helston), representing the British Medical Association; Hemstead (Marazion), Jago (St. Buryan), Richmond (St. Just), R. G. Nesbitt (St. Just), Backhouse (St. Ives), and J. M. Nicholls (St. Ives). The floral tributes were very numerous.

SURGEON-GENERAL JOHN EDWARD TUSON, M.D., who died at Eastbourne on December 24th, 1908, at the age of 79, received his medical education at St. George's and Middlesex Hospitals, and took the diploma of M.R.C.S. in 1851. In 1862 he graduated M.D. St. And., and became a Fellow of the Royal College of Surgeons of England in the following year. He entered the Bengal Medical Department as an Assistant Surgeon, June 17th, 1853, and became Surgeon-General September 8th, 1884, in which year he retired from the service. He served in the campaigns on the North-West Frontier of India in 1855 and 1860, being present with the expedition into the Miranzai Valley and mentioned in dispatches; with the Mahsud Waziri expedition in 1860, when he was again mentioned in dispatches, and received a medal with clasp; and in the Indian Mutiny campaign in 1857-8, including the disarming of the Mooltan population, the operations in Rohilund, and the action of Nugeena; for these services also he was mentioned in dispatches, received the thanks of the Commander-in-Chief, and granted a medal. He was the author of an essay on the hypodermic injection of neutral sulphate of quinine in intermittent fever.

The Services.

TERRITORIAL FORCE.

REMUNERATION FOR MEDICAL EXAMINATION OF RECRUITS. WE have received a letter from a Territorial medical officer protesting against the smallness of the fee (£s.) offered for the examination of a recruit. We agree that this is not adequate remuneration, and believe that strong representations have been made to the authorities without effect. The responsibility for the examination of recruits rests with the county associations, and to these bodies the Army Council forwards ls. for each recruit attested. This, we believe, is offered to the medical officer who carries out the examination, and in many cases accepted, but when no medical man can be found who is willing to accept the shilling the county association has to provide the necessary amount. We do not think that 2s. 6d. per recruit would be at all unreasonable, assuming that the examination is conducted according to the regulations.

R.A.M.C. TERRITORIAL.

A. A. M. writes: I was surgeon-captain in the artillery volunteers. Last year I elected to remain with the artillery in the Territorial Force as a surgeon-captain. I am now gazetted as captain in the R.A.M.C. attached to the artillery. What is my designation and what uniform am I to wear? I am unable to find any definite instructions on these points offered by the War Office.

* * The designation is captain, R.A.M.C. (T.F.). the uniform that of the R.A.M.C. (T.). The only compulsory uniform is the service dress.

Contract Practice.

FRIENDLY SOCIETIES AND MEDICAL CONTRACT PRACTICE.

SIR,—The course adopted by the Denbigh and Flint Division is precisely on the lines advocated by Dr. F. W. Style in the *JOURNAL* of January 2nd, p. 68, and a recital of the mode of procedure may interest those of your readers who are engaged in contract practice work.

A subcommittee was appointed to draw up a code of rules for the regulation of contract practice as applied to sick and benefit societies within the area of the Division. Invitations to attend a meeting for the consideration of the proposed rules were sent to every medical practitioner resident within the area.

The meeting was well attended and after careful deliberation the rules were adopted. A resolution to the following effect was also passed:

That in cases where a medical practitioner serves notice on a friendly society, insisting that he declines to undertake attendance upon the members of such society, except in accordance with the contract rules adopted by the Division, no other practitioner within the area of the Division shall apply for or accept the same.

Copies of the rules and of the foregoing resolution, together with a request that the recipient would sign an "undertaking" not to accept any contract practice appointment except in accordance with these rules, were sent to every medical man practising within the Division area.

The results have been highly satisfactory, and several instances have come to my knowledge where both members and non-members of the British Medical Association have declined to continue to hold certain appointments except on the terms and conditions indicated, and the unwavering loyalty of their *confrères* has secured to them the retention of the appointments on their own terms.—I am, etc.,

E. D. EVANS,

Wrexham. Honorary Secretary, Denbigh and Flint Division.

SIR,—Your correspondent Dr. F. W. Style, in your issue of January 2nd, complains that nothing is done to remedy the grievance of remuneration paid to medical men by friendly societies.

In Newcastle-upon-Tyne and in other places the organization of the British Medical Association is effecting a change, and has so far been successful in its procedure, which, if continued, will gradually eliminate the features objected to.

If Dr. Style cares to communicate with me, I shall be glad to furnish him with some information which may be of assistance to him.—I am, etc.,

GARFORTH DRURY,

Secretary, Northumberland Committee, North of England

Branch, British Medical Association,
55, Pilgrim Street, Newcastle-upon-Tyne, Jan. 7th.

M.D. writes: The statistics given in Dr. F. W. Style's letter are interesting and might well be taken to heart by the bulk of the profession, or at least that portion of it which must needs take contract practice to make both ends meet. I cannot help thinking that your correspondent is just a trifle too optimistic as to results of his proposed circular. As long as the "powers that be" are either unable or unwilling to inflict adequate penalties, which shall touch the pockets of delinquents, so long will the friendly societies continue to prey on us. Some twelve years ago, when practising further south, I held a friendly society appointment in conjunction with a neighbouring practitioner. We divided the club about evenly and got 5s. a head. The club, thinking no doubt to play off one doctor against the other, decided to offer a lump sum for attendance on the whole club. This lump sum worked out at a fraction over 5s. a head. I of course refused to have anything to say to these terms; but my worthy colleague ponched the whole without even a protest—as I ascertained from the secretary. Would any working man fall so low? I think not. This class of individual must be curbed through his pocket, and until that happy day arrives I should advise Dr. Style to sit tight on any appointments he may hold.

THE Danish Paediatric Society which was founded last November held its first meeting on December 2nd, when Dr. S. Monrad, Physician-in-Chief to the Queen Louise Children's Hospital, was elected President. Professor Hirschsprung was elected a honorary member.

Public Health

AND

POOR-LAW MEDICAL SERVICES.

NUISANCE FROM FLIES.

THE Public Health Committee of the London County Council has issued a further report by Dr. Hamer, founded on observations made during the summer of 1908, on the extent to which a nuisance from flies is produced in London by accumulations of offensive matter. The observations were conducted on lines similar to those followed in the summer of 1907, the results of which have already been noted in the *JOURNAL* (May 9th, 1908, pp. 1123 and 1135). In 1908, 141 places of observation surrounding nine sets of premises were chosen. These centres consisted of four depots where stable manure or other refuse was manipulated, two stable premises, a cowshed, a glue and size manufacturer's premises, and a jam factory. The places of observation were generally kitchens or living rooms occupied by poor people; in these flypapers were hung, the flies caught were counted, and the species identified. The investigations confirm the conclusion that collections of horse manure play a prominent part in the propagation of flies. Commenting on this fact, Sir Shirley Murphy remarks: "The need of a power regulating the sanitary condition of stables; and, further, of strict exercise of the powers for requiring the removal of manure at sufficiently frequent intervals, and upon due precautions being taken with regard to such removal, has been long felt, but this need has been greatly emphasized now that it has become realized that the fly nuisance of cities is to a large extent due to neglected conditions at stable premises." Dr. Hamer discusses the possibility that there may be a causal relationship between the prevalence of flies and summer diarrhoea; but upon this question no definite conclusion appears to be warranted.

We have also received a strongly-worded pamphlet by Dr. H. E. Armstrong, medical officer of Newcastle-upon-Tyne, on the dangers of flies as carriers of disease. He suggests that the Local Government Board should be asked to hold an inquiry into the subject. From Dr. Hamer's report it appears that Dr. Copeman, Medical Inspector of the Local Government Board, is engaged upon an investigation of this nature.

BORIC ACID IN MILK.

ON December 31st two summonses issued at the instance of the corporation were heard in the Rotherham Borough Court against milk vendors for selling milk containing boric acid. In the first case the analyst's certificate showed that the milk contained a compound in the proportion of 15 grains of boric acid to the gallon. The summons was for having sold milk not of the nature, substance, and quality demanded by the purchaser, and the Town Clerk contended that boric compounds were not natural constituents of the milk being added as preservatives. Dr. A. Robinson, M.O.H., gave evidence to the effect that boric acid was injurious to health, especially in the case of children and invalids. Taken in any quantity it would cause indigestion, and would after a time produce a rash; in his opinion boric acid was only used in milk which came from dirty dairies, or when the utensils conveying the milk were unclean. The bench imposed a fine of £3. In the second case a dairy company was summoned on similar grounds. The analyst had found crystallized boric acid in the proportion equal to 19 grains per gallon. Dr. Robinson, in cross-examination, said that, although the Board of Agriculture had laid down a standard as to the quantity of milk fat in milk, it had not laid down a standard for preservatives. For the defence it was contended that no case had been made out; the milk was skim milk, and would not be used for invalids and babies; the preservative found in the milk was not present in an injurious quantity; it was suggested that a smaller proportion than 40 grains per gallon was not injurious. The bench imposed a fine of 40s. and costs in this case. The probability of an appeal was intimated.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following degrees were conferred on December 17th, 1908:

M.B., B.C.—G. G. Collet, Trin.

M.A.—A. J. Cardew, Clare.

Mr. J. S. Gardiner, M.A., Caius College, has been appointed University Lecturer in Zoology; and Mr. H. B. Fantham, D.Sc. (Lond.), Christ's College, Assistant to the Professor of Biology.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved at the examinations indicated:

PHARMACY Part I.—*Biochemistry*: K. L. Hart, Davis. *Medicinal Materia and Pharmacy*: W. E. North-Smith, C. J. H. Riches, H. E. Rose.
PHARMACY Part II.—*Anatomy*: R. S. de C. Bennett, J. J. Benyon, H. E. B. Fainalson, A. J. Fainalson, G. F. Malden, H. Rowntree. *Physiology*: R. S. de C. Bennett, J. J. Benyon, A. J. Frädersdorf, C. A. Mortlock-Brown, H. Rowntree.

An Address

ON

MYOMA AND PREGNANCY.

DELIVERED BEFORE THE OBSTETRICAL SECTION OF THE ROYAL
ACADEMY OF MEDICINE, IRELAND.

BY SIR WILLIAM SMYLY, M.D.,

CONSULTING GYNAECOLOGIST TO THE ROTUNDA HOSPITAL, DUBLIN.

My object in this communication is to record a case in which child bearing was complicated by a myoma of the uterus; but I shall first give a short account of the subject generally.

We are all familiar with myomata in pregnant women who are approaching the end of the child-bearing period, which as a rule cause little or no trouble, and are soon forgotten. The few, however, which do cause trouble are noted and published, so that to collect and tabulate the cases which appear from time to time in medical journals would give an altogether erroneous impression of the seriousness of this complication. On the other hand, it must not be forgotten that occasionally serious complications do occur in these cases which tax the skill and resourcefulness of the attendant to the utmost.

We may consider the subject from two aspects: First, the effect of pregnancy on the tumours; and, secondly, the effect of the tumours upon the course of pregnancy, child birth, and the puerperium.

I.

The occurrence of pregnancy in a myomatous uterus causes a change in the position, size, shape, and consistence of the tumours. As the uterus enlarges and rises out of the pelvis, so do the tumours attached to its body. Even those which are attached to the lower segment are drawn upwards towards the end of pregnancy or even during labour, and only cervical tumours or those which grow into the cellular tissue at the sides of the uterus maintain their position or are driven downwards during labour, and are therefore the most likely to cause trouble. As the uterus grows larger and softer so do the tumours attached to it. This change in size and consistence is due to development of their tissues or oedema, the latter condition sometimes causing a rapid enlargement out of proportion to the enlargement of the uterus. At the same time they lose their globular shape, becoming flattened out as the uterus expands, and are more difficult to differentiate from the normal tissues. Necrotic changes are rare during pregnancy, and are generally caused by twisting of the pedicle, but are more common during the puerperium, and may then result in sloughing supuration and general sepsis.

In the puerperium, as the uterus involutes the tumours return to their original condition, and in a few cases have completely disappeared.

II.

If we now turn to the effects of myomatous tumours upon the course of pregnancy, childbirth, and the puerperium, we find that during pregnancy they rarely give rise to serious complications, but that cases have been recorded in considerable numbers in which they caused haemorrhages, abortions, placenta praevia, ectopic pregnancy, intestinal obstruction, ischuria and obstruction of the ureters, with consequent hydronephrosis; twisting of the pedicle with peritonitis; and serious pressure symptoms from the great size of the growth, or from retroversion and impaction of the uterus in the pelvis.

A fact of considerable importance in connexion with pregnancy complicated by myomata is that not infrequently there is great difficulty in forming a correct diagnosis; and as a matter of fact, a large number of uteri have actually been removed in total ignorance of the complicating pregnancy. These mistakes are partly due to the fact that many of the symptoms are common to both conditions, such as enlargement of the uterus, blueing of the vagina and the uterine souffle. Haemorrhage is a common occurrence in pregnancy complicated by myomata, especially in the early months, and all operators should therefore lay to heart the warning given by Olshausen

"that a rapid enlargement of a myomatous uterus accompanied by haemorrhages should always excite a suspicion of pregnancy." In these early cases, too, when the uterus is completely imbedded in tumours, the peculiar softening so suggestive of its condition may be difficult or even impossible to detect.

During labour tumours of the body of the uterus seldom give rise to trouble, and are often overlooked or mistaken for fetal parts, from which, however, with a little care they can be easily distinguished, because they never change their position and cannot be pressed back into the uterine cavity. Not infrequently, however, they cause inertia, and when situated in the lower segment or cervix the latter dilates with difficulty, so that labour may be prolonged over several days. But, as a rule, Nature overcomes the difficulty by drawing up the tumour, or it is pushed down and flattened out by the presenting part. But large tumours adherent in the pouch of Douglas, or which have developed into the subserous areolar tissue, may cause serious and even insuperable obstacles to delivery. Malpresentations are frequent in these cases, and are due either to deformity of the uterine cavity, or to the presenting part being unable to enter the pelvic brim. Placenta praevia occurs with such relative frequency as almost to prove the existence of cause and effect; and the most probable explanation is that the mucous membrane covering the tumour affords such an unfavourable surface that the formation of the placenta is not limited to the serotina, but involves a much wider area, including the reflexa, and therefore more likely to extend into the lower segment.

In the third stage myomata cause trouble much more frequently than in either of the other stages of labour. Imperfect contraction and retraction of the muscular tissue, or retention in whole or in part of the placenta, are frequent causes of haemorrhage. Adhesion of the placenta when implanted upon the tumour itself is especially serious, because the membrane covering submucous tumours is generally so thin that instead of imbedding itself in the decidua, the ovum passes completely through it, and the placenta becomes so intimately connected with the tissue of the tumour that separation may be found difficult, or even impossible; and cases of this kind have been reported in which fatal haemorrhage has followed removal of the placenta, and others in which extirpation of the uterus has proved the only possible way out of the difficulty. Inversion of the uterus due to fundal attachment of the tumour is a well-known complication.

More important because more frequent than any other complication is haemorrhage after labour is completed. It may occur at any time during the puerperium, so that it is difficult to say when a patient with a myomatous uterus is safe. Probably the most frequent and peculiar kind of haemorrhage is that described by Barnes as *paulo-post-partum* haemorrhage. I recorded a fatal case of this kind in the Rotunda Hospital Reports. The patient was delivered in the evening after a normal labour, at midnight there was a violent haemorrhage which was controlled; at six in the morning, a second and fatal haemorrhage occurred; a submucous myoma was found at the *post-mortem* examination. Septic complications due to retention of lochia, portions of the placenta or membranes, or to sloughing and supuration of the tumours themselves are by no means infrequent.

The treatment of these cases, as is evident from what I have already stated, is always a matter of importance and often of grave anxiety to the attendant.

During pregnancy interference is seldom called for, although tumours have been successfully removed without interrupting gestation, but excepting those rare cases in which extreme pressure symptoms, twisting of the pedicle, or sloughing of the tumour render operative interference necessary, it is better to postpone such measures until full term. The induction of abortion, frequently resorted to in former times, has now been altogether abandoned.

At term and during labour those tumours which cause no obstruction or other serious trouble need no special treatment. Polypi should be removed and cervical myomata enucleated, but tumours which grow into the cellular tissue can seldom be removed per vaginam without great danger.

When the tumour is so large and in such a position as

to cause serious obstruction to the passage of the child, we have a number of methods of delivery to select from, and the best choice is often very difficult to determine.

We know by experience that in such cases Nature unassisted will often succeed in overcoming an obstacle which seemed insuperable. This was well illustrated by a remarkable case reported to us by Dr. Kidd, in which a large tumour appeared to fill the pelvic cavity and to offer an insuperable obstacle to delivery. He performed a successful Caesarean section, yet in a subsequent confinement this same woman delivered herself spontaneously. We should therefore make it a rule to wait as long as spontaneous delivery is possible, but not so long as to render operative interference hopeless.

Efforts to drag the fetus past the obstruction by forceps version and extraction, or after perforation, are liable to cause irreparable damage, and are in general to be condemned.

As regards abdominal operation, Caesarean section alone is seldom sufficient. It is more generally advisable to combine it with enucleation of the tumours or extirpation of the uterus. As a rule, panhysterectomy has proved more successful than the supravaginal operation, because, after a prolonged labour, the uterus is often more or less septic, and the retention of a septic stump is not only in itself a source of danger, but its complete removal affords better drainage. Another reason for the complete operation is that the tumours which cause obstruction are always situated so low in the uterus that it is difficult to obtain a stump altogether free from disease.

When the fetus is known to be dead it is better to remove the uterus unopened.

After delivery it is scarcely necessary to point out that *post-partum* haemorrhage must be looked for, and free drainage of discharges secured. And in no other class of cases is complete asepsis from start to finish a more absolute necessity.

I shall now proceed to relate the case:

In September, 1903, I was consulted by a lady, who told me that she had been married eight years, but had no children. She complained of severe neuralgic pains in her breasts, especially at the intermenstrual periods, when they became swollen and painful. Menstruation was regular but very profuse, with expulsion of clots, and lasted a full week generally, but not always accompanied by pain.

The uterus was found to be enlarged, but no tumour was discovered. I diagnosed the case and treated it as chronic metritis.

A year afterwards, September, 1904, she became pregnant and the pregnancy pursued a normal course. Labour commenced on July 5th, 1905, the breech presented and pains were weak and inefficient. On the evening of the fourth day the membranes ruptured and I found the child lying obliquely with the breech in the right iliac fossa. I then made my first internal examination and found the os three-quarters dilated and a head presenting. To the left of the cervix I also found to my surprise a tumour as large as my fist and which I could not push out of the pelvic brim. Having anaesthetized the patient I introduced my hand into the uterus and brought down a foot without difficulty, but extraction proved unusually tedious and the child died before it was completed. Ultimately, however, I succeeded in delivering the dead child without serious injury to the maternal soft parts. After the expulsion of the placenta the uterus contracted well and for some time there was no haemorrhage; but after a time the organ relaxed and enlarged and the discharge became more profuse. The uterus was rubbed and pressed, some clots expelled, and ergot administered with good effect; but after a time the haemorrhage recurred and I washed out the uterus with hot water. The benefit was only temporary, but at no time could the loss be called a flooding; there was no injury to the cervix nor was she at any time bad enough to suggest the advisability of plugging, but still her condition was so unsatisfactory that it was between two and three hours from the birth of the child before we thought it safe to leave the house.

On the fourth day after delivery the lochia became fetid and there was a rise of temperature, which on the following evening rose to 103 F., and the vagina was washed out with creolin lotion.

The following morning she was no better, so I douched the uterus with 1 per cent. formalin solution, after which the temperature sank to normal and remained so for two days. After that it rose again and on the eighth day it was so high and her general condition so unsatisfactory that I asked for a consultation, and Sir Arthur Macan saw her with me in the evening.

Having discussed the advisability of exploring the uterus to see if anything could have been left behind we finally decided to try the intrauterine douche again. Next day her temperature was normal and she gave me no further cause for anxiety.

The numerous complications in this confinement were no doubt all due to the presence of the tumour. The

tedious labour was due to the difficulty in expanding the lower uterine segment. The change in the fetal lie was caused partly by the inability of the presenting part to enter the pelvic brim, and partly to the unequal expansion of the lower segment of the uterus, the left side remaining rigid, whilst the right, becoming overdistended and thinned, would yield to the pressure of the presenting part, which consequently became displaced in that direction.

The hand presentation was due to the lie of the fetus, and its death was caused by obstruction to its delivery and pressure on the cord.

Post-partum haemorrhage is, as I have already pointed out, a common occurrence in myomatous uteri, but is not quite so easy to understand in this case, where the body of the uterus was healthy, and I am inclined to think that it was due to the tumour acting as a ball valve, closing the os and obstructing the escape of discharge, which consequently accumulated in, and by distending the uterus acted in antagonism to its retraction. But whether this was the cause of the haemorrhage or not, it certainly must have been the cause of the retention and putrefaction of the lochia and the septic fever which accompanied it. I had therefore little difficulty in deciding what advice I should give when some months later this lady consulted me again. I explained to her that the tumour, which had then shrunk to about the size of a billiard ball, was at that time doing her no harm, and that unless she again became pregnant would probably cause her no inconvenience. But that in future pregnancies, unless it had been previously removed, she would probably encounter similar dangers to those which she had already passed through.

After some consideration she decided to submit to operation, and accordingly on October 28th, 1905, I opened her abdomen and found the tumour within the left broad ligament, which I incised on its anterior aspect, and enucleated the growth from the cellular tissue and uterine wall into which it was imbedded by about one-third of its bulk. Having closed the cavity with fine silk sutures, I closed the abdomen, and she made a good recovery.

In 1906 she again became pregnant, went to full term, and on April 17th, 1907, delivered herself of a fully-developed living child. Her labour was normal, and excepting a mammary abscess her convalescence was quite uneventful.

A Clinical Lecture

ON

ADENOMYOMA OF THE UTERUS.

DELIVERED AT THE MIDDLESEX HOSPITAL.

By J. BLAND-SUTTON, F.R.C.S.,

SURGEON TO THE HOSPITAL.

ALTHOUGH the pathological condition of the uterus known as adenomyoma was carefully described in a monograph by Professor von Recklinghausen in 1896, and two cases were reported by Cullen in the same year, and many since that date, this disease has not received in Great Britain the adequate attention its importance demands. Cases have been described by Frank E. Taylor, S. Cameron, Tate, Leitch, Uthbert Lockyer, and myself. One of the reasons, and perhaps the chief, which militates against the recognition of adenomyoma is the necessity for a microscopic examination of the tissue, and as this remarkable change in the endometrium is often associated with fibroids, and the symptoms caused by the disease are identical with those set up by submucous fibroids, the nature of the trouble in the uterus is often overlooked. Nevertheless, the tissue changes in the uterus in adenomyoma, in well-marked examples of the disease, are so characteristic that they cannot be mistaken, and the naked-eye features, though they cannot be relied on without the confirmation afforded by a microscopic examination, are often sufficiently marked to lead the surgeon to suspect the presence of this adenomyomatous change in the endometrium.

The specimen which I use to-day to illustrate my lecture is the best example out of fifteen which have come under my observation in the last five years. The

uterus was removed by the subtotal operation from a spinster, 43 years of age, on account of rebellious menorrhagia; the organ completely filled the pelvis, and at the time of the operation measured 40 cm. (16 in.) in circumference. When the uterus was exposed through the abdominal incision in the course of the operation (which was undertaken on the impression that the patient's trouble was due to a large submucous fibroid), I was struck by the peculiar vivid redness of the uterus, and the crown of the organ presented a number of short, ragged villous tufts like soft adhesions. This caused me to remark that I had doubts concerning the nature of the tumour. As soon as the operation was completed I divided the uterus in such a way as to expose the uterine cavity, and on inspecting the cut surface at once realized that this gross enlargement of the uterus depended on changes in the endometrium, and that in all probability we had in hand an exceedingly severe example of diffuse adenomyoma. The parts were carefully hardened, and in due course I made sections through the whole organ.

On looking at the parts, as represented in Fig. 1, it is seen that the walls of the uterus are thickened in a fairly uniform manner, but when the cut surface is critically examined the new material can be distinguished from the strictly parietal or muscular tissue of the uterus; and although it lacks a capsule there is, nevertheless, such a marked distinction between the adventitious and the true tissue of the uterus that the naked eye can fairly well define its limits, and it is possible to trace the line of the endometrium over that portion of the new tissue where it bulges towards the cavity of the uterus. The cut surface of the adventitious tissue differs from that represented by the common hard fibroid in another particular, for instead of forming the well-known vortex arrangement, the muscular tissue is disposed in an irregular manner, and on the freshly-cut surface it produces a pattern not unlike that of the fabric known as "watered silk." When this tissue is examined microscopically, the harder bundles, as already mentioned, consist of unstriated muscle tissue and connective tissue, and the spaces enclosed by these bundles are filled with the peculiar stroma characteristic of the endometrium, and contain gland tubules lined with columnar epithelium of the same type as that which lines the normal tubular glands of the uterus. When isolated sections are examined, the glandular elements appear as islands, but when a consecutive series is examined it is easy to observe that the various glandular tracts are continuous with each other, and, if the investigation involves a sufficiently large tract of tissue, it is possible to follow up the gland tracts until they become continuous with the normal endometrium.

The example just described shows very well the condi-

tions produced when the endometrium is uniformly involved in the adenomyomatous change. In some cases the disease may be restricted to one wall and produce a local enlargement of the uterus. The specimen represented in Fig. 2 illustrates this very well. Here the adventitious mass is formed in the posterior wall of the uterus, and a small nodule which looks like a fibroid projects from the subserous surface of the uterus, and another is embedded in the wall itself. To the naked eye these may be easily mistaken for ordinary hard fibroids, and they often are; but it occasionally happens when such isolated nodules are examined microscopically, they contain the peculiar tissue characteristic of "diffuse adenomyoma," and they are, as it were, the terminal buds of out-runners from the endometrium which have crept through the muscular wall of the uterus, and blossomed under its serous capsule. Pedunculated processes of this kind are more common immediately in the neighbourhood of the cornua of the uterus, and this is explained by the anatomical fact that the walls of the uterus in this situation are thinner

than elsewhere because they are funnelled by the terminal section of the Fallopian tubes. In reference to this, it may be mentioned that the adenomyomatous tissue in the specimen represented in Fig. 1 had involved the endometrium in the left uterine cornu, and had also implicated the mucous membrane of the tube.

The localized patch of adenomyoma which occupied the uterus, represented in Fig. 2, is interesting in another way.

When the specimen was first removed, and the thick mass divided, we could at once discern, even with the naked eye, that the gland spaces in the mass were dilated and filled with colloid material. In some specimens the cystic spaces measure a centimetre or more in diameter.

A sufficient number of uteri affected with diffuse adenomyoma has been examined to show that there is a large variation in the proportions of the two tissues concerned in the pathological formation—namely, the adenoid or glandular element and the myomatous tissue. Judging from my own observations, when the myomatous tissue is in excess, the uterus will be but slightly enlarged and hard, sometimes very hard. In this condition the surgeon will be apt to regard the change as being due to fibrosis unless a very painstaking microscopic examination of the uterine wall is made throughout its whole thickness, in

order to determine the presence of isolated gland spaces, which in some of these hard specimens lack the usual stroma. I am quite certain that some specimens classed as examples of "fibrosis uteri," a diseased condition of the uterus which I described in this JOURNAL in 1899, were really examples of diffuse adenomyoma. When the glandular elements predominate the uterus is much larger than usual, and the fundus of the organ will sometimes

Fig. 1.—Uterus in section, showing diffuse adenomyomatous disease. The polypoid process contains glandular elements. From a spinster 43 years of age.

rise high in the hypogastrium, and then the nature of the disease is scarcely likely to be overlooked when the uterus is removed, unless it be associated with submucous or interstitial fibroids.

In some specimens the glandular tissue may so preponderate over the myomatous that a tumour-like mass is produced with tubular spaces lined with a double row of epithelium; such are sometimes erroneously described as adeno-carcinoma. The naked-eye characters of the organ in such a case further resemble cancer in the fact that polypoid processes project from the free surface of the endometrium into the uterine cavity.

The early investigators of adenomyomatous disease of the uterus, especially Recklinghausen, held the opinion very strongly that these glandular formations could be explained from an embryological standpoint. After an elaborate research, Recklinghausen expressed the opinion that uterine adenomyomata, and especially those about the tubal angle of the uterus, were mainly derived from vestiges of the Wolffian (mesonephritic) and the Müllerian ducts. Cullen has studied the disease with great thoroughness, and has worked out more than seventy specimens, a larger amount of material than has fallen to the lot of any other investigator; he believes that the epithelial elements are solely derived from the normal glands of the endometrium. Cullen somewhat picturesquely describes the changes in this way:

In cases of adenomyoma of the uterus we usually find a diffuse myomatous thickening of the uterine muscle. This thickening may be confined to the inner layers of the anterior, posterior, or lateral walls, but in other cases the myomatous tissue completely encircles the uterine cavity. This myomatous tissue contains large or small chinks and into these chinks the normal uterine mucosa flows. If the chinks are small, there is only room for isolated glands, and where the spaces are of goodly size, large masses of mucosa flow into and fill them. We accordingly have a diffuse myomatous growth with normal mucosa flowing in all directions through it. The mucosa lining the uterine cavity is normal.

There is another side of the question. Now that this disease is more widely recognized, several observers have drawn attention to the frequency with which inflammatory complications of the Fallopian tubes are associated with diffuse adenomyoma of the uterus. It is true that tubal inflammations are fairly common accompaniments of the ordinary forms of fibroids, especially the submucous variety, but the inflammatory complications of diffuse adenomyoma are not only very frequent, but they are by no means confined to the tubal tissues, they involve the peritoneal investment of the uterus also. This is a

matter of great interest, because it may ultimately come to pass that bacteriologists will prove that the tissue changes which lead to fibrosis uteri and diffuse adenomyoma have a microbic origin. Some important evidence in relation to this view of the disease is afforded by the observations of Archambault and Pearce in New York, and by Grünbaum in Berlin. These observers have recorded cases in which adeno-

myomatous uteri have become infected with tubercle. In both cases the women had a tuberculous focus in the lung, and in Grünbaum's patient a few tubercle bacilli were found in sections prepared from the adenomatous tissue in the uterus. Although tuberculous endometritis is rare, the clinical symptoms which accompany it so closely simulate a degenerating submucous fibroid or a mass of adenomyoma that it is extremely likely to be overlooked. In 1904 I removed the uterus from a spinster 46 years of age,

which was enlarged, and its fundus appeared as a rounded body in the hypogastrium. The patient had become profoundly anaemic in consequence of very profuse and frequently recurring uterine bleeding, associated with an elevated temperature. The irregularity of the haemorrhages and the fever led me to attribute these troubles to the presence of a degenerate submucous fibroid. In due course I performed subtotal hysterectomy. The uterus had firm and troublesome adhesions to the rectum and bladder.

On opening the uterus, after its removal, we saw at once that the trouble did not depend on a fibroid, but on a rounded, unencapsuled mass projecting from its anterior wall into the uterine cavity; the diseased tissues extended into the uterine cornua and the terminal sections of the Fallopian tubes. The manner in which the abnormal tissue involved the endometrium is well represented in Fig. 4. I perceived at once that the disease was of an uncommon kind, and Dr. Gabbett kindly undertook the microscopic investigation of the uterus, and found the new tissue to be a tuberculous mass arising in the endometrium. It contained giant cells, epithelioid systems, and

detached pieces of the uterine glands. He also succeeded in finding tubercle bacilli. Reconsidering this specimen in the new light afforded by Grünbaum's observations, it appears to me extremely possible that this was in all probability an adenomyomatous uterus which had become infected with tubercle bacilli. Cuthbert Lockyer has described in detail an adenomyomatous uterus removed from a spinster 48 years of age in which both Fallopian tubes were tuberculous.

It has been already remarked that this diffuse adeno-

Fig. 3. - A magnified section of endometrium showing the peculiar stroma in which the gland tubes are embedded.

Fig. 4. - Uterus laid open by a vertical incision. The endometrium on the anterior wall is occupied by an unencapsuled mass of tuberculous adenomatous tissue. From a spinster 46 years of age. The patient was in excellent health four years after the operation.

myomatous disease of the endometrium lacks a specific symptomatology. The leading clinical features may be summed up thus: It is most common between the thirtieth and fiftieth years, but it has been observed in patients of 20 and in women of 60 years. It occurs in spinsters and in barren married women as well as in those who are fertile. In regard to this matter, Cullen examined the clinical histories of 49 cases of diffuse adenomyoma of the uterus: "Nine patients were spinsters and 40 were married; of these, 6 were sterile, 2 had had miscarriages, and 32 had had children." Among the 16 cases observed by Grünbaum, 6 had borne children. Of the 15 cases under my own care, 7 of the patients were spinsters; and of the 8 married women, 4 were mothers, and 1 had been delivered of fourteen living children.

The symptoms of which the patients complain are profuse menorrhagia, and in severe cases sanguineous fluid may flow from the vagina, sometimes for five or six weeks without intermission. Pain at the menstrual period is fairly common.

On physical examination the uterus is found to be bigger than normal, and in some cases the enlarged fundus may rise high in the hypogastrium. The contour of the uterus may be quite smooth, but in many instances it is irregular. This unevenness may be due to the localization of the adenomyomatous tissue to one wall of the uterus, or the disease may be complicated by the presence of subserous or interstitial fibroids.

It will be seen that these signs and symptoms are those which commonly accompany a submucous uterine fibroid, and it is under this impression that operative treatment is most commonly recommended and undertaken. These are also the signs furnished by fibrotic uteri. When adenomyomatous changes in the uterus are complicated by chronic bilateral infections of the Fallopian tubes, the nature of the affection is very liable to be overlooked, especially when the uterus is only moderately enlarged.

Occasionally a shrewd and experienced observer may suspect adenomyomatous disease before operation; even then the use of the microscope is indispensable for its identification.

TREATMENT.

The only effectual mode of dealing with this disease is removal of the uterus, either by the vagina, or preferably by the abdominal route. Subtotal hysterectomy with conservation of an ovary gives admirable results, immediate and remote. Even in those cases in which the adenomyomatous mass was complicated with tubercle the patients made excellent recoveries, and the condition of these women many months after operation is stated in the reports to have been excellent. It is also worthy of note that no instance is recorded in which hysterectomy has been performed for this disease and the patient has again come under observation with recurrence.

In order to show the uselessness of drugs against diffuse adenomyoma of uterus I will mention the case of a patient who suffered from profuse menorrhagia. An obstetrician of repute thinking she had a submucous fibroid recommended her to take thirty drops of the liquid extract of ergot three times each day. She continued regularly to swallow this stuff for fifteen years. The menorrhagia became so profuse that at the end of this time I was asked to remove the uterus. It was adenomyomatous. The prolonged use of ergot had caused the tip of her nose to become blue and dry, indeed it resembled the nose of a mummy.

REMARKS ON A SERIES OF CASES OF ADENO-CARCINOMA OF THE BODY OF THE UTERUS.

By J. M. MUNRO KERR,

GYNÆCOLOGIST, WESTERN INFIRMARY; OBSTETRIC PHYSICIAN,
MATERNITY HOSPITAL, GLASGOW.

It is very often stated in textbooks that carcinoma of the body of the uterus only occurs in some 2 or 3 per cent. of cases of malignant disease of that organ. This, I believe, is a quite incorrect estimate and has misled the general practitioner into the belief that the disease is very rare.

Within the last year amongst the cases of malignant disease of the uterus upon which I have operated there have been five in which the disease was an adeno-carcinoma of the body. All these cases occurred in my private practice, and in every case the uterus was examined microscopically in the Pathological Institute of the Glasgow University, and the tumours pronounced to be adeno carcinoma.

In three of the cases adeno-carcinoma was suspected. In these the uterus was curetted and the tissue removed was sent to the pathologist. In two of the cases, however, the diagnosis of fibromyoma of the uterus was made, and the true nature of the condition was only recognized after the uterus had been extirpated. I shall refer to these cases later.

In three of the cases the disease had become diffused over the whole endometrium, but in two it was circumscribed. In one of the latter (Case 1) it was so limited that I had almost completely removed the disease with the curette.

The following is a brief summary of the cases:

CASE I.

Miss K., aged 52, was sent to me by Dr. J. S. McKendrick. Patient stated that the menopause came on when she was 49. The only symptom in this patient's case was irregular uterine haemorrhage, which had been going on for three months before she consulted Dr. McKendrick. Suspecting carcinoma of the body of the uterus, I curetted the uterus and had the scrapings examined by Dr. Teacher, who pronounced them to be adeno-carcinoma. I performed abdominal hysterectomy, removing the entire uterus and upper part of vagina, in St. Elizabeth's Home on October 18th, 1907. Upon examining the uterus after operation a small cavity, about the size of a finger-nail, was observed just inside the internal os. On cutting sections through the part it was found that the curette had almost removed the whole of the malignant tissue. The patient made an uninterrupted recovery.

CASE II.

Miss McH., aged 52, was seen by me in consultation with Dr. McMillan, Pollokshields, on November 3rd, 1907. She stated that the menopause had not occurred, and that for fully sixteen months she had been having uterine haemorrhages. These were sometimes very excessive. During the previous four months she was seldom free from a haemorrhagic discharge. She never had any pain, and, indeed, had no other symptoms but haemorrhage. Upon bimanual examination the uterus was found enlarged to about the size of a fetal head. Both Dr. McMillan and I considered the condition a diffuse fibromyoma. Upon November 14th, 1907, in the Park Nursing Home, I performed abdominal hysterectomy, leaving a portion of the cervix behind. After the operation I opened the uterus which had been removed. I suspected the tumour was malignant because of its being so diffuse and friable. My surmise proved to be correct, for Dr. Teacher reported it to be an adeno-carcinoma. I therefore removed the cervix per vaginam a few days later. The patient made an uneventful recovery.

CASE III.

Mrs. E., aged 54, was sent to me by Dr. Gemmell of Coatbridge on March 10th, 1908. The patient informed me that she had three children, and that the menopause occurred when she was 52. Eighteen months later a haemorrhagic discharge began to occur. This continued almost constantly until she consulted Dr. Gemmell a few days before he sent her to me. During the three months before I saw her there was abdominal pain; prior to this she had no pain. Upon bimanual examination an irregular nodular swelling about the size of a fetal head was felt in the pelvis; the uterus appeared to form part of the swelling. I diagnosed the condition as a fibromyoma. She went into the Lyndoch Nursing Home a few days after I saw her. Considering the case to be one of fibromyoma I performed abdominal hysterectomy, leaving only a small portion of cervix. I sent the specimen afterwards to Dr. Teacher, who reported that the myoma had become invaded by an adeno-carcinoma. I consequently removed the cervix per vaginam a few days later. The patient made an uneventful recovery.

CASE IV.

Miss W., aged 61, was placed under my care in the McAlpine Nursing Home by Sir H. C. Cameron in last May. She informed me that the menopause had occurred fully ten years previously. For nearly two years there had been vaginal hæmorrhages. At first these had been irregular and slight, but eventually they had become more profuse and constant. Beyond a feeling of pelvic uneasiness there was no other symptom. Upon examination under an anæsthetic the uterus was found retroflexed and slightly enlarged, but there was no disease of the cervix. Suspecting the condition to be an adeno-carcinoma of the uterine body, I curetted the uterus; in doing so my curette went through the uterine wall. This, however, was attended with no ill-effects. Dr. Teacher reported that the curetted tissue was an adeno-carcinoma. A few days later I removed the entire uterus and a small part of the upper portion of the vagina. Upon examining the uterus after the operation it was found that the tumour tissue extended over the whole internal surface of the body. In some parts it penetrated so deeply into the uterine wall as to almost reach the peritoneum. The patient made an uninterrupted recovery.

CASE V.

Mrs. McE., aged 55, a widow, was sent to me by Dr. Muir, Possilpark, in July, 1908. The patient informed me that she had never been pregnant. The menopause had not occurred, but about three years previously menstruation began to be a little irregular. Eighteen months ago bleeding from the vagina became continuous. At first she had no pain, but during the last few months she had had a good deal of pain in the lower part of the abdomen and back. On examination under chloroform in Miss Tisdall's Nursing Home, the uterus was found to be slightly enlarged and displaced backwards. The appendages were normal. The cervix appeared normal. Suspecting malignant disease of the body of the uterus, I curetted the uterus. The scrapings were examined by Dr. Hasler Wilson, Pathological Institute, and pronounced to be typical adeno-carcinoma. Upon July 22nd I removed the entire uterus and upper part of the vagina. The examination of the uterus after its removal showed it to be extensively invaded by a diffuse friable tumour. The tumour tissue had penetrated in some parts almost through the whole thickness of the uterine wall. The patient made an uninterrupted recovery.

In considering the above cases the first striking feature is the menstrual history. In two cases a distinct menopause had occurred, but in the three others the menstrual discharge had been irregular, then more profuse, then finally more or less continuous. In the former class of case, when bleeding occurs some time after the menopause, there is little likelihood of the condition being overlooked, for a recurrence of bleeding always attracts attention. In the other class, however, both patient and doctor are apt to take up the attitude of presuming that this excessive discharge is simply a feature of the menopause. Such an explanation is only justifiable if the uterus is curetted, and the scrapings have been pronounced non-malignant.

The second point of interest is the age of the patients. The youngest was 52. This is in agreement with the experience of all gynaecologists that the maximum morbidity is between 50 and 60 years of age.

The slow progress of the disease is another matter of interest. In all, except Case i, the disease had been in existence for a very considerable time.

Yet another feature is the fact that three of the cases were unmarried, and only one of them (Case iii) had borne any children. It would appear that while carcinoma of the cervix is favoured by the occurrence of previous parturitions, carcinoma of the body is not, and in fact is relatively more common amongst those who have not borne children.

The frequency of the coexistence of adeno carcinoma and fibromyoma is another striking feature. In the five cases recorded two had distinct multiple tumours, while one had a few small myomatous nodules. This is a matter well worthy of attention. If one looks over recorded cases of fibromyoma of the uterus, in quite a distinct proportion of cases, 2 or 3 per cent. at least, adeno carcinoma of the body of the uterus was found. I have now performed hysterectomy for fibromyoma of the uterus in nearly 150 cases, and in four of them an adeno carcinoma of the body of the uterus was present.

Except for hæmorrhage there are no characteristic symptoms, pain is seldom a marked feature. A feeling of uneasiness and bearing down may be mentioned by the patients, but these are common complaints amongst women. Severe pain is complained of usually only when the disease is far advanced. Small multiple fibroids occasionally are associated with considerable pain. In only one of my cases was severe pain complained of, and in that case there were several small fibroid tumours. The

hæmorrhage varies very much in amount. Occasionally it is very profuse, but it is often quite moderate. It is most likely to be overlooked when it occurs at or about the menopause, for there is often excessive menstruation at that time.

There is only one way of making certain regarding the nature of the condition—namely, to curette the uterus and examine the scrapings. Curettage of the uterus in this condition must be performed with great caution, for if the disease is far advanced the uterine wall is so friable that the curette may very easily perforate it. This happened in one of my cases (Case iv). As a rule perforation of the uterus with a curette is not attended with serious symptoms provided the operation is performed with all aseptic precautions, but with advanced adeno carcinoma there may be a septic condition of the uterus. In the case referred to no evil effects followed.

The absolute importance of curettage in all cases in which there is the slightest doubt is well illustrated by the following one, which was under my care eighteen months ago:

The patient was 61 years of age. She came to me two years previously, and informed me that she was attending another gynaecologist on account of occasional bleeding from the uterus. I advised her to return to her medical attendant and insist upon having the uterus curetted. She did not take this advice, however, and I did not hear of her for two years. She then consulted me and said she wished to place herself in my hands. At the same time she sent me a small portion of tissue which had come away from the vagina, and which on examination proved to be an adeno carcinoma. When I removed the uterus a few days later the whole cavity was filled with tumour tissue, and the uterine wall was almost completely destroyed.

As I have already indicated, the condition is in many cases associated with fibromyomatous tumours of the uterus, whilst in other cases the uterus may be so distended by the tumour tissue that by reason of its size it simulates a myoma.

In the cases in which there are co-existing fibroids, especially if the patient comes under one's care about the time of the menopause, there is a tendency amongst some practitioners to encourage the patient to wait until the menopause is over, with the idea that in time the fibromyomata will cease to give further trouble. Such a procedure is always very questionable, and, as I have said, is only justifiable if the uterus is curetted, and the scrapings are found to be of a non-malignant nature.

There is another important and practical point in this connexion. In cases where the uterus is very much distended with a malignant tumour, and the condition is mistaken for a fibromyoma because of the size of the uterus, the operator, if he performs supravaginal amputation of the uterus, will leave the cervix behind, and may only discover that he has to deal with adeno carcinoma when he splits open the uterus after the operation is finished and the patient has been placed back in bed. In two of my cases this occurred. In both I removed the cervical stump by the vagina a few days after performing abdominal hysterectomy.

All the patients made uninterrupted recoveries, and left the respective nursing homes within the month. At the present time they are all absolutely well.

RUPTURED TUBAL PREGNANCY AT FOUR MONTHS: OPERATION IN A COTTAGE: RECOVERY.*

By T. LISTER LLEWELLYN, M.D., B.S. LOND.,
BARGOED.

I was asked on May 19th, 1908, by Dr. C. Reidy, of Bargoed, to see a case which he had diagnosed as one of tubal pregnancy.

History.

Mrs. J. E., aged 24, married in February, 1906, had had in May, 1907, one child, which was nursed up to May, 1908.

Menstrual History.

The periods started at 17, but were very irregular for the first two years. From the age of 19 they had varied not more than a day. After the birth of her baby in May she missed four periods. Menstruation started again in October, 1907, and remained regular up to January, 1908, after which date it stopped.

* Read before the autumn meeting of the South Wales and Monmouthshire Branch of the British Medical Association.

Previous History.

She had had no illnesses except constant attacks of epigastric pain since the age of 16. In her first pregnancy she was very well throughout, and had none of the usual unpleasant symptoms. Since January, 1908, she had had repeated attacks, sometimes twice a day, of temporary faintness lasting for two to three minutes, associated with a general feeling of weakness. She had no vomiting, but felt sure she was pregnant.

History of Attack.

At 5 a.m. on May 19th, she awoke with severe pains in the lower part of the abdomen. They lasted fifteen minutes, but did not prevent her from getting her husband's breakfast at 6 a.m. She then felt as well as ever, and was able to do a full day's washing. While scrubbing the floor at 5 p.m. she was seized with very severe pains in the lower part of the abdomen. She lay down on the couch, and felt herself getting very weak. She had a hazy idea of Dr. Reidy's visit, and of being carried upstairs. I saw her with Dr. Reidy at 11 p.m. on May 19th.

Condition on Examination.

The woman was absolutely blanched, restless, and unaware of her surroundings. Her breathing was hurried, short, and gasping. The pulse could be felt at the wrist only with difficulty, and it could not be counted. The abdomen was slightly distended and tense, but nothing was made out on palpation. Vaginal examination was quite negative.

Diagnosis.

The history of four months' suppressed menstruation, together with the sudden onset, severe abdominal pain, and obvious internal hæmorrhage, at once suggested the diagnosis of ruptured tubal pregnancy.

Operation.

Dr. W. A. Reidy gave chloroform. The abdomen was opened in the middle line below the umbilicus, and a large quantity of fluid blood at once escaped. On introducing my hand I found a fetus 4½ in. long quite free among the intestines; the umbilical cord had been torn close to its attachment. The right tube was greatly enlarged and funnel shape. It had been ruptured at the extremity. I ligatured the tube, removed the enlarged portion, and left the ovary intact. The left appendages were normal. I then removed several large clots of blood and pieces of the placenta from the pelvis. There was some slight hæmorrhage deep in the pelvis which I was unable to see or locate. To control this bleeding I placed a gauze plug in the pelvis, and then sewed up the abdomen, bringing the plug out through the lower angle of the wound.

The general condition of the patient was still very bad. Six pints of saline were run into a vein at the elbow with very satisfactory results, the pulse improving very rapidly.

After-History.

May 20th.—Plug removed and not replaced. Slight oozing of blood.

May 21st.—Considerable oozing of blood through lower angle of wound.

May 23rd.—Bowels open after calomel.

May 26th.—Stitches removed. Wound completely closed.

The patient made a good recovery. There was no temperature above 99° F. during her stay in bed. Her only trouble was that she was unable to pass her urine for the first week. She came downstairs at the end of four weeks.

Present Condition.

December, 1908.—She menstruated six weeks after operation, and regularly since. The abdominal scar is quite sound, and there is no trace of a hernia.

The case is interesting from several points of view. Rupture of a pregnant tube is rarely delayed until the fourth month. The chief interest, however, lies in the conditions under which the operation was performed. The room was small and almost completely filled by a large, wide, and low bedstead, which had to be pushed against the wall on one side and left 3 ft. clear on the other. The patient lay in, not on, a large feather bed. The light was very bad: a small tin lamp was nailed to the wall above my head and another lamp stood on a table at the foot of the bed. It was practically impossible for Dr. Reidy to give me any assistance beyond handling me instruments.

No sponges were used, their place being taken by a roll of cyanide gauze taken straight from its package. The case ran an aseptic course throughout, and the precautions taken may be of interest. All instruments, needles, and ligatures were boiled. The operation area was surrounded with towels which had been boiled in water for five minutes. Skin and hands were cleaned with soap and

water and lysol. The nursing was entirely left to her neighbours, who were colliers' wives.

I publish this case in the hope that it will encourage other general practitioners to deal with these cases themselves. Delay of even an hour or two may make all the difference between success and failure. I am convinced that asepsis is not difficult to attain even in a cottage.

I am deeply indebted to Dr. Reidy for his skilful treatment of the patient after operation, and for his help in preparing these notes.

PYELITIS OF PREGNANCY TREATED WITH COLI VACCINE.

By H. T. HICKS, F.R.C.S.,

HONORARY GYNAECOLOGIST TO THE DERBYSHIRE ROYAL INFIRMARY.

THE following case is a very typical example of a moderately virulent infection of the right renal pelvis during pregnancy:

S. T., aged 20, was sent to my out-patient department by Dr. Mackay suffering from acute pain in the right side of the abdomen. She was at the fifth month of her second pregnancy, the first pregnancy and labour having been normal in every respect. During the present pregnancy she had been very much troubled with constipation.

The illness started three weeks before admission with aching in the right renal region, beginning behind, but spreading rapidly round to the front of the abdomen and downwards toward the right iliac fossa. The pain was quickly followed by a rise of temperature and a general feeling of malaise. There was no frequency of micturition nor any sign of cystitis.

In spite of a fortnight of incomplete rest in bed at home the symptoms became more marked, and the patient's general condition began to give cause for anxiety. During the first

three weeks the temperature had been irregular, and when I saw her it was 103° F. The pulse was rapid and feeble; the tongue dry and furred. The patient looked pale and ill, and complained of intense pain over the right side of the abdomen. On examination the maximum point of tenderness on deep pressure was below the twelfth rib behind, and there was a definite history of the pain having started here, and of it having spread downwards and forwards into the appendicular and right iliac regions.

There was slight rigidity over the right half of the abdomen, and it was interesting to note the extremely well marked superficial tenderness, which is so often a characteristic sign of pyelitis occurring during pregnancy. The uterus was enlarged to about the fifth month of pregnancy and seemed quite normal. The patient was admitted and was put on a milk diet and a mixture consisting of urotropin (10 grains) and potassium iodide (3 grains). The urine contained pus and a few epithelial casts. It was acid in reaction. There was no tenderness over the bladder, nor was there any evidence of cystitis. A pure culture of *Bacillus coli* was obtained from a catheter specimen of the urine, and a vaccine was prepared. After four days' rest in bed, on the milk diet and medicine, the temperature and pain did not abate; 10 c.cm. of the coli vaccine was then injected. The temperature dropped almost immediately and remained normal, except for one small rise two days later. The pain decreased in severity in a marked manner, so that within a few hours the patient hardly complained at all. She had one or two attacks of slight pain during the rest of the time she was in hospital, but the improvement in her general condition was most satisfactory. The pyuria persisted, but for more than forty-eight hours at a time the urine would be free from pus, and then a large quantity would be passed. After being in hospital a month and a half, the patient went out apparently well in

general health and with the pregnancy unharmed. About three weeks later the pain returned and her general health again became impaired, and she was readmitted. There was, however, no recurrence of the pyrexia, and the patient picked up rapidly with rest in bed and proper dieting. She remained in hospital until full term, when a healthy child was born normally. Four days after delivery the urine was free from pus, and remained so up till now (three weeks later).

There was no difficulty about the diagnosis in this case. The acute onset of the pain, localized at first behind and below the right costal margin, and then spreading rapidly along the course of the right ureter, accompanied with pyrexia and pyuria, left no doubt as to the true nature of the disease. One very prominent feature of these cases is the somewhat diffuse area of great superficial tenderness, which seems to be confined to the cutaneous distribution of the anterior branch of the twelfth dorsal nerve. Pyelitis of pregnancy has to be distinguished in its early stages from pleurisy at the base of the right lung and in the later stages from appendicitis and enteric fever. The knowledge that pyelitis is a fairly common complication of pregnancy, a careful inquiry into the history of the pain, and the fact that the tenderness is most marked behind and below the twelfth rib and along the course of the ureter, together with the intense hyperaesthesia, without much rigidity over the right side of the abdomen, will easily settle any doubt in most cases. The presence of pus in the urine will also give a definite clue to the condition, but it is not by any means safe to negative pyelitis if pus is absent from any given specimen. Several specimens must be examined, and it often happens that the pus does not appear in the urine until some days after the onset of the pain and pyrexia.

No doubt constipation plays a prominent part in the etiology of pyelitis, and almost without exception the infection is due to an invasion of the renal pelvis by the *Bacillus coli*. The renal pelvis is probably infected direct from the colon by means of the lymphatics. It is impossible to accept the ascending theory, because one cannot see why the infection should nearly always be right-sided, and, moreover, the bladder seldom shows signs of infection. In the few cases that I have seen in which the disease was ushered in with cystitis, the infection has been bilateral; and no doubt in these cases, which are far more serious, the infection was ascending. This condition is very different to what may be called simple pyelitis of pregnancy, which, as a rule, runs a very definite and satisfactory course.

The above case shows clearly what I have noted in many of these cases—namely, that the pyuria persists up till the time of delivery, but all the virulence appears to pass out of the organisms as soon as the acute stage is over. Nevertheless, the patients require a considerable amount of care after the acute stage is passed, and they still maintain the pale toxic look which is so characteristic of chronic *coli* absorption. The patient during this quiescent interval should lead an invalid's life. She should be kept warm, and take only very gentle exercise, and her food should consist mostly of milk and farinaceous stuffs. She should take no red meat, and very little fish and other white foods. Alcohol should be strictly avoided. Iron tonics and special attention to the bowels should be insisted upon, and occasional doses of urotropin given. She should accustom herself to drink a considerable quantity of water, especially in the early morning, for flushing purposes. One of the diuretic saline waters will probably be found useful in combination with the urotropin.

She need not be confined to bed, but should take plenty of rest, preferably in the sunshine. If, after the acute symptoms have abated for some time, the patients are treated in the manner outlined above, the pregnancy will in all probability pass on to a normal delivery at term, and at the same time there need be little fear that there will be any permanent damage to the kidney. Should the pyuria persist after delivery, some permanent damage to the kidney substance must be suspected, and the patient should be warned that she may have a recurrence of the disease in future pregnancies, which will possibly result in the formation of a pyonephrosis. One must also not neglect to search for a renal calculus or tubercle bacilli if the urine does not remain free from pus some time after the child is delivered. I have once seen a pyonephrosis develop during the second pregnancy in a patient who had had an attack of pyelitis at the fifth month of her first

pregnancy, but recurrence in future pregnancies is a very rare exception.

With regard to the vaccine, it is, of course, impossible to be sure whether the sudden drop of the temperature and the cessation of the pain in the above case was due to the vaccine or whether it was simply coincidence. I have seen improvement follow the injection of 10 c.cm. *coli* vaccine in other cases of pyelitis, and have no doubt that this treatment should be given a fair trial. If, however, the temperature and pain persist for more than ten days and infection appears to increase in virulence, in spite of the vaccine, dieting, and the administration of potassium iodide and urotropin, the uterus should be emptied.

On several occasions I have seen rapid recovery from pyelitis after spontaneous delivery. No doubt the presence of gestation in the uterus causes pressure on the ureter and prevents free drainage.

The uncomplicated cases of pyelitis run such an even and satisfactory course and the signs and symptoms are so typical that any mistake in the diagnosis must be a matter for regret. The greatest danger lies in mistaking this condition for appendicitis, and since the general appearance of the patient and the acute onset of pain and pyrexia are very similar in both diseases, a hasty conclusion may lead to a disastrous laparotomy.

If the symptoms are prolonged and the infection does not abate within a fortnight on suitable treatment, it becomes a question as to whether the kidney substance itself has not become infected. In one case in which the kidney was explored we actually saw small abscesses in the kidney substance; and although the section of the kidney did no good, for there were many unopened abscess cavities and drainage was impossible, the patient eventually made an excellent recovery, and the pus completely disappeared from the urine after the birth of a living full-term child. If the kidney becomes infected, the possibility of renal pyaemia may be thought of; but since the infection seldom affects both kidneys, there need be little fear of uraemia or anuria.

For practical clinical purposes I should divide the cases of simple *coli* pyelitis of pregnancy into three groups: (1) Mild, (2) moderate, and (3) severe. For the mild forms rest in bed, a milk diet, careful regulation of the bowels, and the administration of potassium iodide and urotropin will probably be sufficient. For the moderate the same treatment should be adopted, with the addition of a *coli* vaccine; and for the severe forms, when this treatment does not meet with success, the uterus should be emptied. It is not advisable to attempt to drain the pelvis of the kidney through the loin, because the patients cannot well stand the shock of the operation, and moreover, if the kidney itself is infected there will be many small foci which cannot be effectively dealt with. By far the safest way to effect free drainage is to relieve the pressure of the uterus upon the ureter. The labour, of course, should be set going by passing a sound or a bougie.

ACUTE INVERSION OF THE UTERUS.

By ALAN W. HOLTHUSEN, L.R.C.P., M.R.C.S.,
HOUSE-SURGEON TO THE LEVETON, WALTHAMSTOW, AND WANDSEAD
CHILDREN'S AND GENERAL HOSPITAL.

The following case is of interest, not only on account of its rarity, but of other points to which attention will be drawn:

On August 23rd, 1908, I was called to Mrs. W., aged 31, a primipara, who had been in labour for nine hours when seen at 5 a.m. The child was found to be in the fourth position of the vertex, with the head imperfectly flexed. At 8.30 a.m. the os was fully dilated, and an attempt was made to improve the flexion of the head. The head being still unrotated two hours later, Dr. S. J. J. Weakley was called in; the forceps was applied under chloroform; the head rotated easily, and the child was safely delivered in twenty-five minutes. The patient soon recovered consciousness. The pulse-rate was then 108.

Only one contraction of the uterus was noticed during the first half-hour after the birth of the child, and 1 c.cm. of ergotin was therefore given hypodermically. The patient was restless from bearing down during this period. The uterus remained soft for half an hour longer, when a sudden violent and painful contraction occurred. This was immediately followed by the protrusion from the vulva of the inverted uterus, with the placenta attached. Very little haemorrhage had taken place up to this point. The placenta was easily and quickly peeled off the inverted fundus, which was at once pushed back by the

doubled-up fist. I sent for assistance, as the patient became suddenly very collapsed—pale, clammy, unconscious, the pulse at the wrist flickering and uncountable. The uterus was quite atonic, and immediately the hand was withdrawn from its cavity it reinverted. The haemorrhage was now considerable. In the absence of Dr. Weakley, Dr. E. B. Randall attended, and the patient was given a further 1 c.cm. of ergotin and 25 grain of strychnine hypodermically, and 2 pints of saline were infused into the right median basilic vein. Meanwhile the uterus was controlled as far as possible by bimanual compression. The patient gradually recovered from the shock; the uterus began to retract; so that at the end of half an hour the compression was no longer necessary. The patient recovered consciousness and inquired eagerly after the baby. Her pulse-rate at this point was 120. The haemorrhage had now practically ceased.

The placenta was not morbidly adherent at any spot; no difficulty was experienced in detaching it from the fundus; it was of the "battledore" variety, and appeared to be centrally situated on the fundus. The cord was only 13½ in. long, and was coiled once round the child's body.

AFTER-HISTORY.

The foot of the bed was raised on a chair. For the first four hours 1oz. of brandy was given every hour in an equal quantity of milk. The patient was also encouraged to drink as much water as she could. Later the stimulant was reduced, so that by the third day the patient was taking 2oz. in twenty-four hours. A mixture was given containing ergot in xv and hyoscymus. The bowels were opened on the fourth day by 1 oz. of castor oil; ordinary light diet was allowed after that day. The ergot was stopped on the sixth day; later a mixture was given containing ferri et amm. cit. gr. x and tinct. nuc. vom. m.

The patient's recovery was uneventful; she got up on the twenty-eighth day. The temperature did not rise above 98.3° F. during the puerperium; the pulse-rate after the second day varied between 76 and 84. The uterus involuted naturally; the lochia were scanty and ceased on the eighth day; they were not otherwise abnormal in any way.

I saw the patient on October 20th, 1908; she was then in her usual good health.

I would call attention to this case for several reasons:

1. Its rarity. Acute inversion of the uterus occurred once in 190,000 labours at the Rotunda Hospital Dublin,¹ and not once in 250,000 labours reported by Braun and Spathe;² 1 in 180,000 to 200,000 are the figures given by Eden.³
2. The extreme uterine inertia, whereby the uterine walls were so lax that, after the uterus had been replaced, it reinverted if the hand were withdrawn from its cavity.
3. The shortness of the cord, which was only 13½ in. long; it was further artificially shortened by being coiled once round the child's body, giving a "practical" length of about 6 in.
4. The characteristic and excessive shock which occurred immediately after the inversion, before any haemorrhage occurred. The shock was out of all proportion to the amount of blood lost, which was probably less than 2 pints.

5. I would call special attention to the value of bimanual compression as a successful means of controlling *post-partum* haemorrhage while the uterus is regaining its tone.

I would suggest the following explanation of the events that took place. The explanation is based upon the theoretical considerations detailed in Champneys's epitome⁴ of Matthews Duncan's chapter on acute inversion.⁵ When the child was delivered by forceps, the fundus, owing to the extreme shortness of the cord, was unknowingly pulled upon. After the birth of the child the placenta and its site were further introverted into the cavity of the relaxed uterus by the weight of the child's body exerting traction on the cord. When the uterus did contract, the introverted placental site acted physiologically as a foreign body; it was, therefore, expelled by the contraction. The uterus then relaxed again; the placenta was removed, and consequently an ordinary *post-partum* haemorrhage occurred from the relaxed placental site, both before and after its reposicion inside the body. This was eventually controlled by bimanual compression. The case would thus fall into the class of "artificial active inversion."⁶

In conclusion, I have to acknowledge my indebtedness to Dr. S. J. J. Weakley and Dr. E. B. Randall, of Forest Gate, for the prompt and successful assistance they gave me.

AN EXPERIMENT IN THE TREATMENT OF EPILEPSY.

By DAVID GOYDER, M.D.,

CONSULTING MEDICAL OFFICER TO THE BRADFORD BOYS' HOSPITAL; CHAIRMAN OF THE HOSPITALS COMMITTEE, BRADFORD FOUR-LAW UNION.

THE Bradford guardians decided to remove the same epileptics from the workhouse to a house, Daisy Hill, in order to test the effect upon them of open-air residence with appropriate occupation, but with entire exclusion of medical treatment or the use of any drugs, it having been asserted that such residence alone would reduce the number of fits, and would probably lead to cure. While still at the workhouse, and on the initiative of Mr. Edward Milnes, the same epileptics were separated from the rest, and under an attendant set to work in the gardens of the house, with the objects of improving their condition and rendering them useful. When I joined the guardians, at the election of 1904, the method of treating epileptics by sodium bromide as salt with their food, and the exclusion of all common salt (chloride of sodium), had so impressed me, that I proposed the addition of this treatment in lieu of any other medicines for the same epileptics whom Mr. Milnes had set to work on the grounds. The proposal was accepted and carried into effect by me. This treatment was continued until their removal to Daisy Hill, and with decidedly satisfactory results.

Upon their removal, and in view of the test as to the value of place, all medical treatment was abandoned, the hope being expressed that they would improve without medicine. During this period the personnel of the guardians was radically changed by the election of March, 1907, and Mr. Milnes's excellent supervision as a guardian was gone. Some time afterwards he begged me to keep an eye on the same epileptics at Daisy Hill, and over a year ago I made systematic visits to Daisy Hill and took shorthand notes of their condition. This supervision I have continued to the present time.

I found that the number of fits suffered by the men had not only largely increased, but month by month got progressively worse; as Chairman of the hospital committee I felt my responsibility for the condition of these men, and I took upon myself the duty of altering that condition. I made up my mind that this state of things and this test of place should at once be put an end to; and through Dr. Spark and Mr. Carter it was determined to see that the bromide salt treatment was strictly carried into effect. Dr. Spark is the accredited attendant at Daisy Hill, and under his supervision the new treatment, when determined upon, was cordially carried out.

The following table and comments show the conditions of things from January, 1907, to October of the same year, at which date I intervened:

TABLE I.

No. of Men.	Date.		Fits.	Increase.
	From	To		
10	Jan. 1, 1907	Jan. 31, 1907	65	
10	Feb. 1, ..	Mar. 12, ..	69	(About 6 weeks.)
10	Mar. 13, ..	Apr. 13, ..	58	
10	Apr. 14, ..	May 11, ..	55	
10	May 12, ..	June 8, ..	80	16
10	June 9, ..	July 6, ..	70	
9	July 7, ..	Aug. 3, ..	90	2
9	Aug. 4, ..	Aug. 31, ..	90	
9	Sept. 1, ..	Sept. 28, ..	100	5
9	Sept. 29, ..	Oct. 26, ..	113	48
9	Oct. 27, ..	Nov. 23, ..	108	
			898	in 11 months.

It will be observed that although from July to November the number of men was reduced to 9, the increase in the

number of fits was progressive from 25 to 48. At this stage—namely, November, 1907—the administration of the bromide salt was begun, and the results are seen in the following table:

TABLE II.

No. of Men	Date.		Fits.	Decrease.
	From	To		
9	Nov. 29, 1907	Dec. 27, 1907	70	45 from Sept.
9	Jan. 3, 1908	Feb. 22, 1908	25	53
9	Feb. 23, ..	Mar. 21, ..	50	
9	Mar. 22, ..	Mar. 31, ..	15	(In 9 days)
9	Apr. 1, ..	Apr. 28, ..	59	
10	Apr. 25, ..	May 23, ..	13	100 from Sept.
10	May 23, ..	June 20, ..	50	
8	June 21, ..	July 18, ..	21	
8	July 19, ..	Aug. 15, ..	19	
8	Aug. 16, ..	Sept. 12, ..	9	104
8	Sep. 13, ..	Oct. 10, ..	4	103
7	Oct. 11, ..	Nov. 7, ..	5	
6	Nov. 8, ..	Nov. 30, ..	7	

In 12 months 317—Nov. 1907 to Nov. 1908.

Less fits by 581 than 1907.

It is to be noted that in April and in May-June the number of fits largely increased—this was due to the omission of the salt by the attendant; this man was admonished, but his carelessness was repeated, and he was replaced by another who has proved himself thoroughly reliable, with the result seen at the end of the table. It is also to be noted that the number of epileptics treated fell from 10 to 8, and ultimately to 6, 1 having been removed to hospital for an abdominal operation, but the general and almost continuous fall in the number of fits from 113 a month in October, 1907, to October, 1908, when there were only 4 in the month, sufficiently proves the efficacy of the treatment. The greatest number of attacks, 113, occurred in October, 1907, increasing from the previous July, when only 9 instead of 10 men were under treatment, whereas in Table I when 10 men were again under treatment, that is, from April 26th, 1908, to May 23rd, 1908, the number of fits fell 100 below those recorded from September 29th to October 26th, 1907, before any treatment was begun.

In observing the effects of the bromide salt treatment, it is found that when the epileptics come under its full influence they become rather listless, stupid, and drowsy; this is the expected result, and a result to be attained; it indicates the point of saturation of the system by the salt, the point when the fits become controlled; the dose daily can then be diminished one half, but not altogether discontinued. The drowsy, listless, symptoms soon pass off and the patient is fit again for work. It should be said that the administration of the salt is not confined to giving a definite amount with the three daily meals, but their bread is specially baked for them, the amount of common salt usually mixed with the dough is excluded and is replaced by an equivalent quantity of the bromide salt.

Some eight or ten years ago two French physicians, MM. Toulouse and Richet, discovered that the desired effects from sodium bromide were interfered with when sodium chloride was allowed to be used in the food. When the common salt was excluded from the food, the good effects of the bromide immediately became pronounced; the cause of antagonism was supposed to be decomposition of the salts in the body when taken together. The results were published in the *BRITISH MEDICAL JOURNAL*, and Dr. Enrich read a paper on the same results in his own practice before a meeting of the Bradford Medico-Chirurgical Society. I immediately thereafter tested the treatment in my private practice, with most satisfactory effects in several cases.

The amount of bromide given by experts to patients largely exceeds the doses given by general practitioners,

Dr. McCallum of Kendal, the medical officer of the Starnthwaite colliery and school for epileptic boys, with whom I corresponded after my visit to Starnthwaite, gives 1 to 2 drachms or even more in a day. Our dose may have been a third or sixth of this in mixture, but now the bromide salt we give at meals and with the bread approaches more to his, as he believes, necessary standard. He pushes the doses to saturation of the system, indicated by the diminution or ceasing of the fits, and some degree of drowsiness and stupidity of the patient; but he alleges that this condition does not in any way impair the ultimate intellectual capacity, which returns when the doses are reduced and the fits subside, but he continues the bromide until assured that the attacks are subdued. It is no use trifling with epilepsy if any permanent results are to be achieved; the treatment must be strong, continuous, and well watched. In some cases the salt produces an eruption, but this can be met by cleanliness and appropriate applications; better the rash a hundred times than the epileptic nerve storm and convulsive spasms of the epileptic fit. There is no proof that the mere place of residence has any influence on the ultimate cure of the disease; change of place does diminish the fits for a time, but they ultimately recur and continue as bad as or worse than before; what is wanted is adequate treatment, not change of place.

ON THE FLAGELLATION OF LYMPHOCYTES IN THE PRESENCE OF EXCITANTS BOTH ARTIFICIAL AND CANCEROUS.

HOME FOR INCURABLES.

PRELIMINARY NOTICE.

In a recent paper¹ we have described how the plasmata of patients suffering from carcinoma will excite amoeboid movements in the leucocytes of healthy persons. In another paper,² which will be published shortly, one of us has shown how leucocytes can also be excited by placing a drop of blood on a film of agar jelly containing a mixture of methylene blue and atropine. In yet another paper³ experiments are detailed which show how this atropine excitant can be so modified as to reduce its poisonous effects, and also that by omitting the agar jelly it can be prepared in a liquid form which enables it, still remaining effective, to be mixed with blood. In this last paper several formulae for making the excitant are given, and among them is one prepared from the following solutions:

1. A volume of Unna's polychrome methylene blue (Grübler) is diluted with an equal volume of water.
2. A neutral solution containing 4.5 per cent. sodium citrate, 1.5 per cent. sodium chloride, and 0.225 per cent. atropine sulphate.
3. A 5 per cent. solution of bicarbonate of sodium.

Of these solutions mix together in a test tube 1 c.cm. of the diluted stain, 4 c.cm. of the citrated solution, 1 c.cm. of water, and 0.2 c.cm. of the sodium bicarbonate solution.

Into a capillary tube draw up a volume of this mixture, and add to it an equal volume of the blood to be examined, freshly drawn from the finger. Incubate the tube at 37° C. for half an hour, and then place a drop of the mixture on to a slide, and cover with a cover-glass, which may be gently pressed down if the blood will not spread. The slide should be examined at a temperature of 20° C.

The granules, but not the nuclei, of the leucocytes are well stained. The polymorphonuclear cells can usually be distinguished by the arrangement of the granules which outline the many-lobed nucleus. The eosinophiles of course have large granules which stain well.

In from a quarter to half an hour these cells will extrude long snake-like pseudopodia identical with those seen when agar jelly is employed, because they have absorbed the excitant with the stain while they were in the incubator.

In the first paper to which reference has been made,¹ we have shown that when a cancer patient's blood is mixed with an equal volume of a certain solution of sodium

citrate in a capillary tube, and its plasma, obtained by centrifugalization, mixed with one-eighth of its volume of a healthy person's blood, and then incubated for half an hour, and the slides prepared and examined as above, some of the leucocytes will show the same exaggerated movements. The blood plasma of apparently healthy people occasionally causes the leucocytes of another healthy person to throw out pseudopodia, but if the effects of the cancer plasma be compared with those of the healthy, it will be seen that the movements caused by the former are exaggerated as compared with those produced by the latter. We are therefore of opinion that the plasma of cancer patients contains some excitant for leucocytes.

In the present paper we desire to direct attention to the behaviour of the lymphocytes of healthy people in the presence of the excitant, whether it be cancerous or that composed of methylene blue and atropine. If the slide, prepared according to the stain-containing formula which has just been given, be examined, the small mononuclears will readily be recognized by their size, which is much less than that of the other leucocytes. By this method of *in-vitro* staining (for the granules of the colourless cells become stained) the lymphocytes present rather unusual characters. Most of the textbooks state that they are either non-granular or only contain very small granules, and in fixed films when the cells are killed this usually appears to be the case. When, however,

Sketch of two flagellated lymphocytes and one polymorphonuclear leucocyte, showing exaggerated amoebic movements.

they are living and resting in the stain-containing excitant, it will be seen that the cytoplasm of the small mononuclear cells contains a few deeply-stained granules arranged round the nucleus. These granules may be, and generally are, larger than the granules of the polymorphonuclear cells, though slightly smaller than those of the eosinophiles, and they are further differentiated by the very bright way in which they stain, so that they appear of a brilliant scarlet colour compared with the granules of other cells. It will be noted also that the granules will appear to collect in masses in the cytoplasm round the nucleus.

If the specimen is passed rapidly under the objective (preferably $\frac{1}{2}$ in.), and all the leucocytes examined in turn, suddenly the eye will be arrested by a larger cell which also contains the same sort of bright scarlet granules as are seen in the small mononuclears. We believe these cells to be the large mononuclears or large lymphocytes. Their granules are larger than those of the polymorphs, and slightly smaller than those of the eosinophiles, but they are fewer in number and usually more discrete, and may be collected in masses, as in the case of the smaller cells. By careful observation the outline of the single nucleus may be made out, for it will not be stained, the cells being alive. If the nuclei are stained the cells are dead,⁴ and the excitant has been wrongly prepared. The specimen should be searched and all the lymphocytes carefully examined, the other cells, although they will probably be showing exaggerated movements, being neglected.

We will now describe how these lymphocytes may become flagellated, though it must not be supposed that

flagellation always occurs, for sometimes we see it in every specimen and at other times numerous preparations may be examined without its being observed although the same exciting solution is employed.

Suppose the specimen has been prepared with the methylene-blue formula and the slide is being carefully searched for cells large and small (for lymphocytes of both sizes may become flagellated), which have bright discrete granules, suddenly one meets with a cell, which may or may not be extruding pseudopodia, probably not, and which appears to have a granule which is dancing about, as though by Brownian movement, just outside its cell wall. A close scrutiny will show that the granule is attached to the cell by a thin, hair-like filament. Sometimes this flagellation begins immediately after the slide has been prepared, at other times it may take an hour before it begins, and, as we have stated, it may not occur at all. The cell should be watched and it may be seen that the flagellum is slowly extruded until it may become longer than the width of the cell. Occasionally cells will be found with several flagella extruded, all waving about in the surrounding plasma. We have seen a cell almost surrounded by twenty such flagella. They nearly always have a dot or granule at the distal end and may have others at intervals in the length of the filament. On one occasion we have seen these flagella exhibiting what appeared to be lashing movements. They must not be mistaken for the pseudopodia thrown out by the cells in the presence of the excitant; the pseudopodia, which are much thicker, may continue to be slowly extruded and retracted for some hours, and they generally contain no granules. The flagella, unlike pseudopodia so far as our experience goes, never become retracted, but usually break off in a short time. They must not be mistaken for fibrin, which is much thicker than a flagellum, and it must be observed that if the excitant is correctly prepared, no fibrin will be present as coagulation is prevented. They are quite characteristic and we do not think they will be mistaken once they are seen.

Up to the present we have only seen flagellation occur in those cells, large and small, which have bright staining granules, and as we shall show later, we are of opinion that they are lymphocytes, though when we first saw them we thought they were a variety of eosinophile owing to the size of their granules.

The phenomenon of flagellation was seen by one of us more than a year ago, when he had made the excitant in liquid form, but it was not until more than six months later that one of us suggested that there might be a similar excitant in cancer. The reasons for this suggestion have been fully given in a former paper, together with the steps taken to demonstrate it. The flagellation-producing properties of the blood plasma in cases of carcinoma were observed in one of the early cases which we investigated (a case of cancer of the pylorus). In this case, as in the others, eight volumes of the citrated plasma of the patient were mixed with one volume of the blood of one of us, and having incubated the mixture in a capillary tube and made the slide in the usual way, we found that some of the lymphocytes had become flagellated in precisely the same manner as had so often been seen when the artificial methylene blue excitant was used, though in this experiment there was neither methylene blue nor atropine present.

Since this case we have found that the plasma of several cancer patients have caused healthy people's lymphocytes to become flagellated, but we have not succeeded in demonstrating this phenomenon in every cancer case. On the other hand, we have never yet seen it occur with the plasma of persons other than cancer patients unless artificial excitant was added. In stating this it must be remembered that we have not seen flagellation in many cases, and we do not wish to be dogmatic, for it is quite possible that we may yet find it produced by the plasma of other persons.

We wish to take this opportunity of pointing out that we have recently found excited movements in the leucocytes of healthy persons produced by the plasma of persons who are not apparently suffering from cancer, though the movements so produced are not so marked as those caused by cancer plasma, and the two can be differentiated. We are experimenting with a modification of the citrate solution with which we mix the blood, as we

find that a 3 per cent. solution of sodium citrate sometimes itself excites the production of short pseudopodia. By this means we hope to get a better contrast between cancer and other plasmata. It will be necessary to make a large number of experiments before we can satisfy ourselves that other persons' plasmata never excite amoeboid movements to the same extent as we have found to be characteristic of those produced by the cancer plasmata, or cause lymphocytes to become flagellated.

The next question is: Is flagellation a living phenomenon or is it a *post-mortem* effect? We consider that it must be a living phenomenon, because not only can the extrusion be watched, but we have also seen a flagellated cell extruding and retracting long snake-like pseudopodia. Moreover, the cover-glass has been carefully removed from a slide in which flagellated cells were seen, and was then dropped on to an agar film which contained excitant, when all the cells immediately showed excited movements even if they were not doing it in the first slide.

We have stated that the cells with bright staining granules or masses in the cytoplasm, which appear to be the only ones which become flagellated, are the mononuclear leucocytes or lymphocytes. The identity of the small lymphocytes is conclusive owing to their small size, and in order to determine the class of the larger cell with brightly-stained granules in the cytoplasm we succeeded in staining their nuclei and so clearing up their nature by the following experiment:

A specimen was made with artificial excitant, as described in the early part of this paper. Some flagellated cells were seen, and the appearance of the brightly stained granules noted. An agar film was prepared which contained a sufficiency of stain and alkali to stain the nuclei of lymphocytes at 37° C. in ten minutes.¹ The cover-glass was carefully removed from the first slide, and without allowing the adherent leucocytes to dry, was dropped on to the agar film. A field was found which contained a cell with brightly stained granules. The slide was then incubated at 37° C. for ten minutes. Since the agar film contained sufficient stain and alkali to stain the nuclei in ten minutes, it was found on removal from the incubator and examination of the same field that the cells which had brightly-stained granules contained large single nuclei, which showed them to be lymphocytes. This experiment has been repeated many times.

Up to the present, therefore, we feel justified in stating that it is only the lymphocytes which present brightly staining masses or granules in their cytoplasm, and that it is only these cells which become flagellated.²

There is yet another reason which shows that these cells are the ones commonly known as lymphocytes; we mean the almost invariable presence in them of centrosomes. If blood is placed on a jelly which contains sufficient stain and alkali, and is kept at such a temperature as to cause the granules of the leucocytes to stain deeply, every lymphocyte will be seen to contain one, two, or three brightly stained small round or oval rings lying in the cytoplasm. (These have been illustrated in a former paper.) We presume that these bodies are centrosomes, but as far as can be seen the lymphocyte is the only leucocyte which contains them. They can always be seen on the jelly which excites amoeboid movement in leucocytes. They may be small rings or ovals, and sometimes appear thickened on one side like a signet ring, or they may be semilunar or horse-shoe shaped. They are always present, and can be readily found with a 1 in. objective.

Professor Ronald Ross, who invented the jelly method of *in vitro* staining, has frequently seen these rings. He thought that they might be what are commonly known as nucleoli because they appeared to be within the nucleus. When the cell is spread out between the jelly and the cover-glass, as the nucleus is so large the centrosomes will generally appear as though they were within the nucleus, whereas in reality they are situated outside it, that is, above or below it. One of us who has seen them a large number of times also thought they were nucleoli until he saw them lying in the cytoplasm beyond the edge of the nucleus. Moreover, they become stained long before the nucleus,

and cells will live and be very active with their centrosomes stained, but die if the nuclei are stained. The centrosomes must not be mistaken for "red spots,"³ which begin as small points, and attain a large size, whereas a centrosome (if such it be) is always the same size, and never appears to alter. A red spot is homogeneously coloured, whereas a centrosome is ring-shaped, and only its circumference will colour. As stated above, we have never seen a similar centrosome in any blood cell except a lymphocyte, and if the cells with brightly staining masses or granules in their cytoplasm are placed on stained agar, they will generally exhibit one, two, or three of these rings.

We wish to take this opportunity of stating that, although we have examined a very large number of fresh blood cells by this *in vitro* method of staining, we have never yet seen any sign of a mitotic phase in a cell, though of course we have only examined blood from the peripheral circulation.

At this stage we have no right to speculate as to the nature of these flagella; but perhaps we may be permitted to suggest an hypothesis which we have discussed with several of our friends who have seen this phenomenon. Anyone repeating the technique for demonstrating the excitant for leucocytes in cancer plasma is practically certain, sooner or later, to come across these flagellated cells, so that the advancement of a theory as to their nature, although it may be based on few facts, may not be amiss. The flagella usually separate off and progress through the plasma nodule first. Whether this progression is due to a living movement or to streams in the plasma is difficult to determine. Sometimes they look very much as if they had the power of movement. They can easily be seen to break off, and can be followed if the microscope has a mechanical stage. They usually either stick to a red cell or get lost among them.

About a year ago a lymphocyte which had become flagellated owing to artificial excitant was shown to Dr. E. H. Ross, of the Egyptian Public Health Department, Port Said, and he remarked upon the resemblance which it presented—though a possible association between flagellation and cancer was then quite unthought of—to the gametocyte of malaria. When he saw the separation he also suggested that the flagella were spermatozoa.

Now this is a suggestion which may be of the greatest importance, an importance which is greatly increased if flagellation is produced by a possible excitant in the plasma of persons suffering from carcinoma. We are aware, and Dr. E. H. Ross was also aware, of certain cytological difficulties in the way of the suggestion. But these difficulties are by no means insuperable, and do not render the suggestion impossible. In this paper we shall not go into these cytological problems, as our original intention was merely to record the facts as seen by us. Yet we will draw attention to the possibility of the brightly staining masses and granules in the cytoplasm being chromatin, and to the dot or nodule at the ends of the flagella being composed of one of these granules. Hermann, quoted by Walker,⁴ has described chromatin bodies in the cytoplasm of cells, deriving them from the nucleus, and it has been suggested that this may be the extrusion of the male element. If the flagella are spermatozoa, and if they are produced by some excitant in the plasma of cancer patients, they may play an important part in the causation of the disease. It is impossible to say what cells may be fertilized by these spermatozoa, if they are such, and we do not propose to speculate further.

In conclusion, we may add that we have not yet been able to fix a flagellated cell on to a slide, because the filaments break off on being handled. If a specimen containing cells with brightly staining granules in the cytoplasm is fixed on to a slide and restained, the brightly staining granules and masses seem to have disappeared in the process of fixation.

¹ Dr. Stevens has informed one of us that he has in the tropics seen red cells apparently become flagellated, but he has never seen a leucocyte appear like the one he saw in our laboratory. This is referred to in the *Practical Study of Malaria and Other Blood Parasites*, second edition, by Dr. Stevens.

NOTE ON THE TREATMENT OF PERNICIOUS ANAEMIA.

By BYROM BRAMWELL, M.D., F.R.C.P.E.,

SENIOR ORDINARY PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, ETC.

DURING the past year I have met with two cases of advanced pernicious anaemia in which, after a certain degree of improvement had taken place under arsenic, arrest of the improvement occurred, and in which the administration of iron was then attended with very marked and rapid alteration for the better.

It has for long been recognized that in typical cases of pernicious anaemia, in which the colour index is above the normal and each individual red blood corpuscle contains more than the normal amount of haemoglobin, the administration of iron is usually unattended with benefit, and is in many cases apparently injurious. This certainly has been my own experience; but I have met with some exceptions, amongst which the two cases to which I have just referred are perhaps the most striking. The notes of one of the two cases are as follows:

Mrs. P., aged 54, was admitted to the Edinburgh Royal Infirmary on September 1st, 1908, complaining of weakness, bleeding piles, and swelling of the feet.

History.

The patient stated that she had been a strong, healthy woman until three years previously; she then had an attack of what she termed "jaundice"; this lasted for seven weeks; she has had two other attacks of the same sort since, the last about a year ago. For thirteen years she has been troubled off and on with bleeding piles; for some months before her admission to hospital the piles had been worse.

Condition on Admission to Hospital.

Temperature 99.2°, pulse 108, respirations 32; extremely pale and anaemic. The face had a yellow tinge, but there was no jaundice; the feet were swollen. The patient was not emaciated, but stated that she had lost a good deal of flesh lately.

The blood showed all the characteristic features of advanced pernicious anaemia. The red corpuscles numbered 545,000 per cubic millimetre, the haemoglobin equalled 15 per cent., the colour index was 1.2, the white corpuscles numbered 3,800 per cubic millimetre. The differential count was as follows: Polymorphs, 73 per cent.; small lymphocytes, 19 per cent.; large lymphocytes, 7 per cent.; eosinophiles, 1 per cent. The red corpuscles showed marked poikilocytosis; no normoblasts or megaloblasts were found.

The appetite was poor; the patient complained of thirst. The bowels were constipated. All the teeth were absent. The patient stated that she had had no teeth for three years, and that she had for a long time only had one or two teeth; she further stated that she had not suffered from dental caries or from a sore mouth; her teeth simply dropped out, and did not decay.

The tongue was slightly furred; the liver was considerably enlarged, projecting $\frac{3}{4}$ in. below the costal margin; the spleen was somewhat enlarged.

The patient was very short of breath and suffered from palpitation, and at times faintness. The pulse was 108, soft and weak; the blood pressure 120. Blowing systolic murmurs were heard in all the cardiac areas, most marked at the apex.

The urine contained a trace of albumen but no casts or other abnormal constituents.

There were no haemorrhages in the retina; the fundus oculi was pale, the optic discs normal.

Treatment.

Gradually increasing doses of arsenic, commencing with 2 minims of Fowler's solution three times daily, increased every fourth day by 1 drop. The maximum dose, which the patient was able to take was 10 drops three times daily.

Progress and Result.

Under this treatment great improvement rapidly took place. On October 1st, the patient was looking and feeling very much better, and the condition of the blood showed a marked improvement—the red corpuscles were 1,800,000, the haemoglobin 50 per cent., the colour index 1.2. From October 1st to November 10th, although the general condition improved, there was no alteration in the state of the blood. On November 11th Robertson's Bland's pill capsules—one No. 3 capsule (equal to three Bland's pills) three times daily—were prescribed. Under this treatment striking improvement in the condition of the blood immediately took place. On November 20th, the red corpuscles equalled 3,000,000, the haemoglobin 60 per cent., and the colour index 1.2. On November 23rd the patient was discharged from hospital, and advised to continue the iron. On January 13th, 1909, when she was last seen, she stated that she was perfectly well. She looked very well—many years younger than on her admission to hospital. The blood examination showed the red corpuscles 4,100,000, the haemoglobin 65 per cent., and the colour index 0.7.

It is important and interesting to note that the iron produced a marked and rapid increase in the number of red corpuscles, and that after the administration of iron the colour index fell from 1.2 to 0.8.

* Arsenic prescribed.

† Iron prescribed.

‡ Patient discharged from hospital on November 21st.

The fact that the patient had had no dental caries and no glossitis and that there had been no oral sepsis is an interesting point. I have met with and recorded some other cases of pernicious anaemia in which the same fact has occurred. I consequently doubt whether oral sepsis has the important influence in the production of the disease which some authorities have suggested. I am disposed to think that the glossitis from which many patients who are affected with pernicious anaemia suffer is a consequence rather than a cause—due, presumably, to the same toxin, whatever it may be, which is the cause of the anaemia.

SOME REFLECTIONS REGARDING THE FREE USE OF BACTERIOLOGICAL CULTURES FOR THE DESTRUCTION OF RATS AND MICE.

By DR. J. DANYSZ,
THE PASTEUR INSTITUTE, PARIS.

Owing to the general use of certain microbic cultures for the destruction of rats and mice, field mice, rabbits, and other small rodents, the question of a possible danger which these cultures may present with regard to the health of human beings has lately been raised.

The destruction of vermin is of course most important, both from a hygienic and an economic point of view. Rats and mice are the principal propagators of the plague, and probably of many other contagious diseases; we know, also, that rats and mice in warehouses, etc., and mice and voles in the fields, are often the cause of enormous damage. In France, for example, in the year 1903, field mice did nearly a million pounds worth of damage to the crops, and the scourge was only stopped by applying in the fields a virus prepared at the Pasteur Institute in Paris at the request of the French Government. In Great Britain, according to recent estimates, the damage caused by rats amounts to as much as £10,000,000 per annum.

It is incontestable that the introduction of raticide viruses has played a most important part in the campaign against these animals, nor must we forget that the application of these bacteriological methods for practical purposes is only of recent date, and that they have not yet been brought to complete perfection. It will readily be admitted that it is only since the introduction of these methods that the systematic and scientific study of the destruction of rodents has begun, and that it is solely by persevering in this direction, and by taking advantage of

every resource offered by science, that serious and lasting results can be obtained.

It would, therefore, be most undesirable in the general interest, if the free development of this science and of this new industry were prevented, as we should thereby be denied the advantage to be gained by practical experiments and trials with biological methods, in the campaign against destructive animals. It would be most unscientific to do this without sufficient reason.

The viruses of Loeffler, Danysz, Issatschenko, Neumann, and Dunbar belong to the group of microbes called *Salmonella* or *Bacillus enteritidis*. According to the most recent investigations, two types are to be distinguished among these bacilli, differing from each other in several biochemical characteristics.

Type I, to which belong the bacillus of Loeffler, of hog cholera, and of psittacosis, all apparently identical with the *Bacillus paratyphus* B.

Type II, to which belong the bacilli of the viruses of Danysz, Issatschenko, Neumann, and Dunbar, which seem to be identical with the *Bacillus enteritidis* of Gaertner.

The bacillus of psittacosis, discovered by Nocard during an epidemic among parrots, must be placed in a special category, as it appears to be very dangerous to man. All the other bacteria belonging to the *Salmonella* group call for special examination. The bacillus of hog cholera was for a long time considered to be the cause of this disease, but we now know with certainty that, although this bacillus is often found in the excreta and in the blood of pigs affected with cholera, yet it is in reality another microbe, invisible under the microscope and able to penetrate porcelain filters, which is the real agent of the disease. The visible microbe is a concomitant of no importance, unable to cause hog cholera in pigs. I lay great stress on this point, as it has a most important bearing on the subject.

The investigations of the American bacteriologist, Salmon, have incontestably shown that if the blood or the serum of a pig that has died, or is ill with cholera, are filtered, and if another pig is inoculated with these liquids, freed from all visible organisms, it will become infected with the disease, whilst inoculation with the visible bacillus, which has up to the present been looked upon as the sole agent of hog cholera, produces no appreciable effect. Thus we have a microbe which has for many years unjustly borne a bad reputation, and it is only now, since the existence of microbes invisible under the microscope has been established, that we are able to do it justice and declare it to be quite inoffensive.

Is it not possible that similar circumstances may obtain with respect to the microbes of Flugge and Gaertner, and particularly with those of the raticide viruses, which, whilst bearing great resemblance either to the *Bacillus paratyphus* B or to the *Bacillus enteritidis*, differ considerably from them as regards their biological characteristics, especially in their virulence?

Cases of infection through food are comparatively rare, as appears evident from the very small number of cases reported in medical literature in the course of a year, and yet, surprising as it may seem, large quantities of preserved meats, smoked or salted hams, sausages, etc., and even smoked sturgeon, contain bacilli belonging to the groups *Paratyphus* B and Gaertner.

Valuable light has been thrown on this question by the recent investigations of Drs. Muehler, Dahm, and Fuerst at the Institute for the Study of Infectious Diseases in Berlin.¹ They bought at random, in the shops of Berlin, fifty-seven specimens of preserved meats, and subjected them to minute bacteriological examination. Some white mice were also fed with portions of each. The results were quite unexpected; forty of these portions of meat gave characteristic diseases to the mice, which in the majority of cases proved fatal, but upon the autopsy of the mice cultures identical with *Bacillus paratyphus* B and the Danysz virus were found, while in the meat none of either the one or the other of these microbes could be traced.²

Since Couradi and Uhlenhuth first drew attention to the frequent presence in Nature of paratyphic bacilli they

¹ This fact does not prove that there were no pathogenic microbes in the incriminated samples, but it proves in an incontestable fashion that preserved meats may produce serious accidents in connexion with which *Bacillus enteritidis* may be found in the blood of the victims, while at the same time it may be impossible to discover these microbes in the articles of food which have caused the illness.

have been found everywhere—in articles of food and in the excreta and the urine of perfectly healthy persons and animals. Huebener³ found *Bacillus paratyphus* B in various kinds of *charcuterie*, fresh and preserved, of which he and his family partook without the slightest evil effects. Rimpand⁴ found the *Bacillus paratyphus* B in the excreta and the urine of eleven perfectly healthy individuals, none of whom had come into contact with persons suffering from disease. Uhlenhuth, Huebener, Nylander and Bohtz⁵ have frequently found the bacillus of hog cholera or *Bacillus paratyphus* B in the normal contents of the intestines of pigs.

It should be noted that in 1903-4 nearly 600,000 litres of cultures of the Danysz bacillus were distributed in France, in different departments, for the purpose of destroying field mice; that for more than ten years some hundreds of litres of virus have been distributed every week for the destruction of rats, and that consequently more than a million persons have handled this virus without taking any special precaution, and that, in spite of that, no appreciable case of illness has resulted, either in man or among domestic animals.⁶

CONCLUSIONS.

The following points should receive special attention:

1. Mice die after having eaten meat, and show the presence of the *Bacillus paratyphus* B or Gaertner's bacillus in the blood, whilst these microbes could not be discovered in the meat itself. (Muehler, Dahm, Fuerst.)

2. Small and large quantities of food containing the *Bacillus paratyphus* B or Danysz virus have been eaten by human beings, without the slightest evil effects being apparent. (Huebener, Danysz.)

3. *Bacillus paratyphus* B is often found in perfectly healthy human beings. (Couradi, Uhlenhuth, Rimpand, and others.)

The following conclusions would, therefore, appear to be justified:

1. That the microbes of the *Salmonella* group are extremely widespread in Nature.

2. That, if these microbes are found frequently in cases of poisoning through food, it is far from being proved that they are the active agents in these occurrences.

It is much more probable, as maintained by Professor Marx,⁷ that they are due to ptomaines or other poisons emanating from foodstuffs more or less tainted, and that the microbes in question are only inoffensive concomitants, as in the case of hog cholera.

In the course of the above-mentioned investigations Drs. Muehler, Dahm, and Fuerst have once more confirmed the value of the raticide viruses; they found notably that the Danysz bacillus killed more than 50 per cent. of wild and over 90 per cent. of domestic rats.

I think, therefore, that microbic cultures which have been handled for more than ten years by more than a million individuals, and which have been scattered broadcast on bread or grain in many parts of the world and placed within reach of domestic or other animals without causing any serious accident, cannot reasonably be considered dangerous.

⁶ With a view of showing the many opportunities of infection which were afforded by the methods adopted when applying the virus over large areas, it may perhaps be of interest to describe in detail the manner in which it was distributed. For an area of 1,000 hectares (2,500 acres approximately) a quantity of 1,000 litres (225 gal. approximate) of the virus was employed, and from 1,200 to 1,500 kilos. (24 to 30 cwt. approximate) of crushed grain was soaked with it. If sufficient receptacles were not to be had to contain all this grain and liquid, the grain was put on the floor of a schoolroom, a barn, or the large room of an inn, the virus poured over it, and the mixture effected by means of spades. The bait, thus prepared in the morning, was distributed in the fields during the afternoon. For the purpose of distribution, a large number of the inhabitants of the village were requisitioned—men, women, and even children of over 12 years of age. Each person received some of the soaked grain in a basket or some other receptacle, and they used their hands to place it where required. One man was able on an average to lay the necessary bait for 1 hectare (2½ acres) in a day, and as the work had to be finished as quickly as possible, many persons were thus occupied for several days in succession. The bait was apt to stick to the hands, to the garments, to the baskets, and to everything with which it came in contact. The peasants, and especially the children, absorbed it more or less; the animals on the farms, game, and birds ate considerable quantities of it. The inhabitants of about 1,000 parishes in France were thus brought into contact with the virus.

ACUTE PANCREATITIS FOLLOWED BY PANCREATIC ABSCESS: OPERA- TION: RECOVERY.

By CARRICK H. ROBERTSON, M.B., B.S. LOND.,
F.R.C.S. (ENG.).

SURGEON TO THE WAIHI DISTRICT HOSPITAL, NEW ZEALAND.

Up to the present time there are few men who had the felicity of diagnosing a case of acute haemorrhagic pancreatitis before abdominal section; but in order that this privilege may be transferred from the few to the many it is necessary that these somewhat obscure cases (though not, it seems, so very uncommon) should be reported, in the hope that some points may be elicited which will help to make the clinical picture of this disease more complete.

The following case of acute haemorrhagic pancreatitis was followed subsequently by a pancreatic abscess and eventual recovery:

M. R., a married woman, aged 46, was admitted to the Waihi Hospital, New Zealand, on June 24th, 1908.

History of Attack.

Early on the morning of June 23rd she was seized with acute agonizing pain in the abdomen, accompanied by very frequent vomiting and sweating. She vomited about every half-hour, and, from the description, it was evidently very severe. The bowels moved once just after the pain began. At the end of twenty-six hours the pain lessened and the vomiting stopped; she was then brought to the hospital, a distance of some eight miles.

Condition on Admission.

The temperature was 100° and pulse 90. She complained of severe pain just above the umbilicus, and there was a little general abdominal distension. She would allow only the gentlest pressure on the abdomen, but it was not anywhere rigid. There was no jaundice; the face was rather pinched but not in any way "Hippocratic"; in fact, she did not look very ill.

Previous History.

It appeared that she had frequently had attacks of abdominal pain, the first occurring about seven years ago. Latterly the attacks had become more frequent, and after the last one, three months ago, she became jaundiced. The attacks were usually associated with diarrhoea. Dr. Cheesman, of Karangahake, had told her she had gall stones, and advised removal, but her aunt had died after an operation for gall stones, so that she was reluctant to undergo one. She had for a long time suffered from "indigestion."

Progress.

On admission enemata were given without result. The next day she seemed a little easier, although the pulse was a very little faster. On June 26th the bowels had not moved and the distension was increasing. The distended transverse colon showed below the umbilicus. No flatus had been passed. The pulse had increased to 120 and the tongue was very furred; she had not vomited but felt a little sick. There was no jaundice and the liver dullness was present. Pain was still definitely located at a spot about 1 in. above the umbilicus in the middle line. The upper part of the abdomen moved better in respiration than the lower. Rectal and vaginal examination proved negative. A few hours later she began to vomit again and immediate operation was decided on.

First Operation.

June 26th, 1908. An incision was made in the middle line, cutting out the umbilicus. On opening the abdomen, fat necrosis of the omentum was immediately noticed. The incision was now extended upwards, and a large quantity of blood-stained fluid was found free in the abdominal cavity. In the region of the head of the pancreas a large hard swelling, feeling about the size of a Tangerine orange, was palpated. On lifting up the stomach and omentum, many necrotic patches were seen in the fat round the region of the duodenum. In spite of gentle handling a hole was torn in the gastroduodenal omentum, just below the pylorus; this exposed the head of the pancreas, which was seen to be intensely engorged and the dark red colour. The tear had caused considerable oozing from vessels on the surface of the pancreas. It was now seen that all the structures in this region (except the pancreas) were unduly softened and friable, due to the action of the digestive ferments; this would account for the tear in the gastroduodenal omentum. Two small swabs soaked in adrenalin were passed into this tear, and attention turned to the distended condition of the bowel. It was not so distended as to warrant puncture, and a long rectal tube was threaded; on passing the tube a quantity of light yellow faeces evacuated; on passing the bowels more ran out. The gall bladder was small and thickened, and had two enlarged tortuous veins running over the surface; one stone was felt in it. The swabs were now removed from the rent in the pancreas; the bleeding had stopped. A gauze tube was passed down to the head of the pancreas through the hole in the gastroduodenal omentum and brought out of the upper end of the wound. A second tube was put down towards the pelvis. A small incision for drainage purposes was also

made through the abdominal wall about the level of the tip of the tenth rib and a tube passed down from here into the right kidney pouch. This tube was removed in forty-eight hours.

The next day the pulse was 100 and temperature 99°. There was a little vomiting but no pain since the operation. The patient felt comfortable. Rectal saline injections were given every four hours for two days. Sips of water and champagne were given for twenty-four hours. Tympanitis was still troublesome but it could always be relieved by the rectal tube. On June 28th a turpentine enema was administered with good result. She was now on peptonized milk. The wound required dressing twice a day. The patient got on well, and had a normal temperature until July 7th, when she had occasional attacks of pain, which reminded her of the pain she had experienced with previous attacks of "gall stones." At this time also the temperature began to rise, until on July 12th it was 102.8° and the pulse over 100. The abdomen once more became tender and tense. As the discharge coming away from the tube leading down to the head of the pancreas was becoming less and the temperature rising, further operative interference became imperative in spite of the low general condition of the patient; in fact, she was now in a worse condition than she had been since entering the hospital, and the following operation was performed as rapidly as possible; the time occupied was about thirty-five minutes.

Second Operation.

July 13th, 1908. Mayo Robson's incision for exploring the gall bladder was made with the patient on a sand pillow. Firm adhesions were met with fixing the liver to the colon and the great omentum. The great omentum showed patches of fat necrosis, but they were yellow and smaller than on any other occasion. There were also small filamentous adhesions about every patch of necrosis seen in the field of operation. The adhesions were separated with some bleeding, exposing the fundus of the gall bladder and part of the duodenum. A probe was then passed down the sinus leading from the original median incision, and it was found to end in adhesions just above a small hole leading into the region of the head of the pancreas. Swabs were packed into the kidney pouch and all round the site of the operation, and with the finger the opening in the pancreas was gradually enlarged. About an ounce of foul pus escaped, and the finger found itself in a cavity with smooth walls containing a necrotic piece of pancreas; this was removed with forceps, and was found to be about an inch and a half long by half an inch wide. Considerable arterial bleeding was now encountered from somewhere about the mouth of the abscess cavity; this was very troublesome, but finally stopped on pressure with a swab soaked in adrenalin.

Stones could be felt in the cystic duct and two in the common duct, but as the patient was in anything but a favourable condition I simply incised the thickened gall bladder, and tied in a small tube, hoping that some of the stones would eventually come out. No bile escaped, showing complete blockage of the cystic duct. The incision was closed after seeing the head of the gall bladder to the peritoneum and passing a large drainage tube well into the abscess cavity in the head of the pancreas and another into the right kidney pouch. The sinus in the original median incision was closed with fishing gut; 1½ pints of saline were then put into the right basilar vein, and the patient put back to bed.

The next day flatus was passed, and the bowels were moved; but there was considerable pain in the wound, and for the first time blueness of the lips and blue spots in the cheeks were noticed. From now on the temperature gradually came down to normal, but it was not until a fortnight after this operation that the temperature kept steadily on the normal line. The gall bladder drainage tube came out about seven days after the operation, and the tube from the pancreatic abscess was removed after the temperature became normal. A small gall stone came out of the wound about a week after the operation, and seemed to give the patient much relief; ten days after this six small pale stones appeared in the dressings, which were unfortunately thrown away by the nurse before I could examine them, but from the glimpse I had of them I should think they were pancreatic calculi.

On August 27th the temperature again rose suddenly to 103°. This was due to an abscess in the left arm, which discharged the following day just before I had arranged to incise it. No other rise of temperature was observed. Several times during the illness the urine was tested for sugar, but none was found. Cammidge's reaction I was unable to try.

She was discharged from the hospital on September 6th, feeling quite well.

Up till the time the abdomen was opened I must admit that the diagnosis of pancreatitis had not entered my head. I have thought since that if I had seen her in the first twenty-four hours when the vomiting and pain were so intense I might have considered it, but she did not come to the hospital until this had subsided. The reason for operation was that the symptoms of obstruction were becoming marked and the general condition of the patient worse. The diagnosis made before operation was obstruction due to an impacted gall stone, on account of the comparatively gradual increase in distension and the previous history of the patient. A symptom which has been described in these cases is that the abdominal distension

is more marked above the umbilicus, whereas in this case the abdominal swelling was more marked below the umbilicus, owing to the distension of the colon. No pancreatic tumour was felt, owing perhaps to the difficulty of palpation due to the general tenderness of the abdomen. The only symptom which seems now to have pointed strongly to pancreatic inflammation was the constancy of the tender point 1 in. above the umbilicus. A perforated gastric ulcer might have caused this, but in this case the liver dullness was always present, and neither the appearance of the patient nor the abdomen was at all suggestive of this latter condition, for the abdominal wall, though tender, was not rigid, and the distension was very slow in becoming marked, making the clinical picture more one of intestinal obstruction than peritonitis. I do not think this case would have required the second operation for the pancreatic abscess if I had made a deeper incision in the pancreas: as it was, the drainage tube must have lifted away just enough to prevent free drainage.

On October 19th, 1908, I saw this patient again, and she was in good health and felt quite strong, but is troubled with a small fistula leading from the gall bladder out of which a small quantity of mucus issues. At date of writing, November 16th, 1908, the patient is quite well, and the fistula has been healed for about three weeks.

ARROWS AND ARROW WOUNDS IN NORTHERN NIGERIA.

By ALLAN C. PARSONS, M.R.C.S.Eng., L.R.C.P.,
WEST AFRICAN MEDICAL STAFF, N. NIGERIA.

The weapon of war most generally used among pagan races of Northern Nigeria is the bow and arrow; even the more civilized races, who fight on horseback with spear or sword, generally include a strong company of archers among their forces. The arrow is also used in the chase, and is then, as far as one can learn, anointed with the same poisonous substances that are prepared for human quarry. Native big game hunters, who may have access to gunpowder, fire their arrows (which are much stouter than the ordinary bow arrow) out of Dane guns at close quarters; the hunter in this case is often the first to fall! There seems to be no objection among the natives to eating the flesh of game killed by these weapons. The arrow consists usually of a simple barb made from local iron mounted on a shaft of stout reed, the whole measuring about 2 ft. in length. They are usually very neatly made, and as many as thirty or forty arrows can be carried in one quiver. A winged arrow is practically unknown, but this is explained by the fact that the arrow is not meant to kill, but is simply a poison carrier; consequently they are generally discharged at close range, though instances are on record of men being hit at ranges varying from 150 to 200 yards.

Usually the first intimation that hostilities have commenced is a shower of arrows shot into the air, but there is no doubt in the bowmen's mind as to where they are to fall, and a few generally find their billet. Other tribes, especially hill pagans, adopt other tactics and go in for sniping at close quarters—a most unpleasant experience for those sniped at.

The bow apparently does not come in for nearly the same amount of care in its manufacture as do the arrows, though it seems to fulfil its purpose quite well.

There is great difficulty in extracting from the natives any reliable information as to the composition of their poisons, and there seems to be a different recipe for each district. Evidence is accumulating to show that in nearly all the Northern Nigerian poisons some form of *strophanthus* plays a part. The composition of the poisons, however, is never simple, but consists of various animal and vegetable ingredients which may have a local reputation for being noxious. Thus the inspissated juice of various cacti and euphorbiae is a favourite ingredient with hillmen, while the roots, leaves, and fruit of other wild plants are often incorporated.

Animal secretions in a state of decomposition are said to be used by some of the more savage tribes. The people in one district are credited with the manufacture of a poison so deadly that only the very aged and feeble are allowed to make it. Others, again, adopt the simple method of

using a decomposing carcass as a sort of pincushion for infecting their arrows. Finally, there would appear to be districts where the tetanus bacillus abounds, and arrows are rendered poisonous by merely planting them head downwards in the soil.

The native is particularly reticent (and often cunningly misleading) about a matter that affects him so closely, but the results of sending home all available specimens of poisons is encouraging. The poison paste, as seen on the arrow heads, has a dark and often varnished appearance: it is partly soluble in water, a resin-like substance being frequently precipitated. In all probability old paste loses most of its poisonous properties; injections into animals with old material generally produce no result. It would seem that the natives themselves realize this fact, for they generally "brew" a fresh supply of poison before starting on any raiding expedition, or in anticipation of a visit from the white man and his troops. On more than one occasion I have noticed that the marksmen are accompanied by poison bearers, who carry the poison in a fresh and liquid state enclosed in small gourds. The Bowman then inoculates each arrow as required by dipping it into the poison cup.

Nearly all the samples of arrow poisons from Northern Nigeria that have been sent to the Imperial Institute for analysis have been found to contain *strophanthus* and strychnine, besides several other substances physiologically unimportant. Both poisons are derived from plants growing locally.

The injuries from arrows range in severity from a mere skin scratch to the transfixion and laceration of some deeply placed organ; and the seriousness or otherwise of such wounds depends upon the part of the body hit and the character of the poison used. As far as my observations go, the individual powers of resistance on the part of the patient need not be considered, as the troops sent on an expedition are all picked men in sound health. The temperament and fatalistic tendencies of the native soldier, however, should always be remembered, as these factors certainly affect the prognosis.

The range at which an arrow is fired greatly affects, of course, the degree of its penetration, and the resulting wounds are proportionately serious. A deep artery may be wounded, or fatal haemorrhage may occur from the transfixion and laceration of some internal organ. I have come to believe, too, that the toxic effects of a poisoned arrow are enhanced by the depth of the wound it causes. In the first place, the poison is more easily rubbed off under such circumstances; secondly, the arrow head must necessarily remain a certain time *in situ*, thus allowing the poison to be absorbed; and, lastly, remedial measures are more difficult to adopt if the wound is deep.

A wound from a poisoned arrow should always be considered serious, however slight the injury may appear, and whatever part of the body is affected. Perhaps wounds of the limbs are less dangerous than most others, while wounds that affect serous membranes or vital organs are naturally graver on account of the attendant complications.

As mentioned above, the age of the poison is important; it may be old enough to be inert, or the paste may require a little time in contact with the blood and fluids of the body to be dissolved and absorbed. It may be taken for granted that no surgically clean arrow ever leaves the bowstring, so that sepsis has to be guarded against in any case.

The clinical symptoms vary considerably, as might be expected from the composite and uncertain character of the poison. Slight wounds that do not penetrate far beneath the skin generally do well and give rise to no symptoms if treated on sound surgical lines. Deep wounds, however, are more serious, and the accompanying table, which is extracted from the medical report on the Chibbuk expedition in 1907, shows briefly the history of the 10 fatal cases which formed 20 per cent. of the total casualties on that occasion.

It will be seen that the dangerous cases arrange themselves roughly into three groups:

Group I includes those cases in which death follows rapidly (quarter of an hour to two hours) upon the injury as the direct result of the poison, or from haemorrhage. The clinical symptoms here are those of a failing heart, and it is not always easy to say whether the patient is dying from a heart poison or from internal haemorrhage.

Case.	Length of Life after being Hit.	Nature of Injury (Arrow Wounds).	Remarks.
1	½ hour	Deep wound of back	Strychnine injections probably too late. In Case 2 also tannic acid not used at once, as the soldier thought slightly of his wound.
2	½ hour	Slight wound of thigh	Arrow extracted; death from syncope.
3	1 hour	Right lung pierced	Died almost at once on reaching hospital.
4	1½ hours	Right lung wounded	Patient brought in collapsed, and died in a few moments after admission.
5	1 hour	Left kidney wounded	Wound apparently clean, but cellulitis set in on the third day.
6	5 days	Perforating wound of forearm	Spreading cellulitis; death from meningitis; arrow extracted by patient; cellulitis.
7	36 hours	Frontal sinuses pierced	Tannic acid used early; arrow extracted by patient; cellulitis.
8	30 hours	Deep wound of thigh	Tannic acid used early; tetanus supervened thirty hours before death; wound apparently healthy.
9	8 days	Deep wound of buttock	Tannic acid used early; incisions for cellulitis, which cleared up; tetanus supervened twenty-four hours before death.
10	7 days	Forearm perforated	

When first seen the wounded are generally in a state of collapse, and the condition of such patients seldom warrants surgical search for internal bleeding. Diagnosis in such cases as 1 and 2, however, is not as a rule difficult. The stricken man with cold and sweat-covered skin, whose dilated pupils show no reaction, and whose pulse is slow, small, and irregular, presents a picture that is fairly easily recognizable.

Group II comprises cases in which apparently the heart poison is not at work but in which septicæmia sets in some hours or days after the injury. A certain number of cases are bound to become septic, but there are other wounds (of which Nos. 7 and 8 in the above table are instances) which apparently are aseptic in the beginning and give no cause for alarm. In those cases that end fatally there is a very rapidly-spreading oedema of the cellular tissues with high temperature, and the infection is probably erysipelatoid.

Group III contains what may be called the "convulsive" cases. Here the diagnosis is of some special interest as the spasms may be due either to tetanus or strychnine poisoning. In Cases 9 and 10 the early appearance of trismus, the tonic nature of the spasms, and the late onset of the symptoms generally, made the diagnosis of tetanus fairly certain; moreover, the samples of poison which were sent to England for analysis were declared to be free from strychnine.

The treatment of poisoned arrow wounds must necessarily be prompt, and where several cases are brought in at once the deepest wounds should receive first attention. Since promptitude is so important, and the surgeon cannot attend to each case immediately, I instruct the Europeans and the native non-commissioned officers in the principles of first aid. Each European engaged with the troops is supplied with a lancet, dressings, pure carbolic acid, and tannic acid, while each native section commander also carries a supply of tannic acid and bandages. In this way much time is saved. The procedure adopted whenever possible is as follows: A ligature is placed above the wound, which is then sucked by the wounded man himself or a comrade (the dangers of the practice are, of course, fully explained); the arrow is extracted when necessary and the wound cauterized by a glowing stick or by pure carbolic. The ligature is now removed and bleeding encouraged; finally tannic acid powder is packed into the wound and a dressing applied. In wounds of the face and other parts where ligation is not possible, manual compression should be tried and the wound excised or scraped, according to its size.

The French colonial surgeons place great reliance on tannic acid in the treatment of poisoned-arrow wounds. After using it in nearly 100 cases, I certainly think it has a curative action, provided that it is applied to the wound early enough. The exact method of its action does not seem quite clear, but possibly, besides constricting the blood vessels, it may form some insoluble or inert com-

pound with the active agents of the poison. Clinically it is observed that the efficacy of the drug varies inversely with the depth of the wound. It may be mentioned that the native soldiers have great belief in the drug, and such faith, of course, means a great deal in the treatment of sickness.

The after-treatment of simple cases is conducted on rational lines; a brisk purge is given as soon as possible, while stimulants and light food are generally indicated for the first few days. The more serious cases will require further treatment. In the first place, I think it is always advisable, in the case of natives, to remove the arrow if it has not been already extracted by the wounded man himself. Even where the case is hopeless, the patient generally wishes to be rid of his "thorn in the flesh," and I think in such circumstances the medical officer is justified in acting in accordance with the patient's wishes, rather than in following his own surgical instinct. Where an arrow has transfixed a limb, it is often better to thread the barb right through; much time is thereby saved, as backward delivery is often difficult; moreover, better drainage is thus established.

In the heart poisoning cases hypodermic injections of strychnine are indicated, and every attempt should be made to rally the patient. Each moment is precious, and while the wound is being attended to by an assistant, the surgeon should be injecting strychnine.

Obvious puncture of a large artery calls for ligation which should be well above the level of the wound on account of the possibility of septic infection and secondary hæmorrhage.

Cases of cellulitis require early and extensive incisions and generally prove very troublesome amid the rough and ready conditions of bush practice. A point worth remembering in such cases is, that baths, whether for the whole body or for the local treatment of wounded limbs, can be easily extemporized by excavating the ground and lining the cavities with waterproof sheeting.

It is best to isolate convulsive cases in some quiet part of the camp. The strychnine cases should be treated with the ordinary antidotes, but the tetanus cases do not seem very amenable to treatment. Chloroform and morphia would seem to be the only remedies as far as symptomatic treatment is concerned. The latter drug should be pushed and feeding conducted by enemata. In the absence of any antitoxin nothing more can be done beyond keeping up the patient's strength, and relieving distress.

In the general treatment of wounded soldiers in bush fighting it is well to remember one or two points. All wounds, of course, must be treated on strict antiseptic lines, though it must be admitted that compliance with these ideals is not always easy. Beds are very rarely available on active service, but it is important that patients with wounds should not lie on the bare ground, and native mats or ground sheets are generally available. Shade will be essential, and protection against dust storms and rains must be ensured. The water supply will need careful attention, and drinking water should be boiled before use. The food difficulty will arise quite early, and since the soldier's wife does not accompany him, other arrangements will have to be made. These, of course, will depend entirely upon local conditions, but, in any case, the medical officer will be amply repaid for any trouble he may take over the material comforts of his patients.

No real remedy for arrow poisons appears to exist among the natives themselves. Charms, of course, are popular, and they generally consist of small portions of a Koran bound up in leather, but almost any small article may be considered as a *ju-ju* according to the faith of the wearer.

At a recent meeting of the Zoological Society of London a paper by Dr. A. E. Brown, Secretary of the Zoological Society of Philadelphia, was read on the tuberculin test in monkeys. The paper described experiments recently carried out with a view of suppressing tuberculosis in monkeys. At the same meeting Professor E. A. Minchin read a paper on the flagellates parasitic in the blood of fresh-water fishes, in which five species of *Trypanosoma* and four species (two new) of *Trypanoplasma*, from fishes of the Norfolk Broads, were described in detail. Particular attention was paid to the minute structure of the parasites, and it was shown that it is possible to give a uniform description of the nuclear apparatus of both *Trypanosoma* and *Trypanoplasma*.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE USE AND ABUSE OF THE CURETTE.

I THINK the profession ought to feel deeply indebted to Dr. Herman for his timely and outspoken remarks on the above subject in his lecture published in the *JOURNAL* of December 5th, 1908. That the curette has become, in the hands of many medical men, by its too frequent and uncalled-for use, a weapon of offence, there is a deplorable wealth of evidence.

As a general practitioner, in my early days of practice I used the curette with a frequency for which I now chide myself. I learnt by experience that those cases of neurasthenia, with pain and aching in the iliac or hypogastric regions, with anaemia, leucorrhoea, and the other attendant symptoms, were not at all benefited by the operation of curetting to which I had submitted them, unless I except some little benefit derived by a few through the subtle suggestion of an operation. But I found that all those cases after operation required a more lengthy period of rest in bed to effect a cure than did my later cases whom I treated simply with rest in bed, plenty of natural food and sleep, douching, and sometimes tamponade. A general practitioner is more in a position than a consultant to learn the true nature of the causes which have induced the neurasthenic condition. More especially true is this in the case of newly-married women, who seem now to be resorting in droves to this operative procedure for relief from symptoms begot purely by a profound change in their lives, and at a time when the nervous system, unable to adapt itself to its new surroundings and conditions, exaggerates every little worry into a life's tragedy. A case I had a few years ago may illustrate my contention.

A dressmaker who had suffered for years from anaemia, dyspepsia and dysmenorrhoea, married. Her husband suffered from habitual insomnia and constipation following on an operation for appendicitis—a constipation only relieved by a daily enema. These and other troubles threw the newly-married wife into neurasthenia with pain especially in the ovaries and uterus. A few weeks' rest in bed with local treatment benefited her. She rose from bed and removed to a new house, which brought back a return of the congestion in the pelvic region. I had finished attendance before she removed. Her anxious husband on the advice of his friends consulted a specialist. I received a note from the latter saying that my patient was suffering from some enlargement of the body of the uterus with some atony of the muscular wall with a narrowed long cervix, that the operation of curetting was imperative, and that no conception was possible without an operation. The anxious husband had two or three weeks to cool his ardour for operation (during which time he learned that a friend's wife had had a similar operation performed upon her and nearly died from peritonitis following it). He went from one extreme to the other. I was asked to call again to see the patient. In my judgement the operation seemed unnecessary. I ordered rest, douching and tamponade for at least six to eight weeks. I attended to the husband's constipation and alleviated the insomnia. I had to discontinue the treatment of the wife in four weeks as I found she was pregnant. I have since attended her during two confinements.

Another case which came under my notice emphasizes certain points to which I have referred.

A married woman living apart from her husband suffered very much from metrorrhagia with enlargement of the uterus. Living in lodgings and lack of funds compelled me to send her to hospital. She was curetted, and on the second day after operation was obliged to walk from a private to a main ward. This brought on haemorrhage more severe than she had experienced, which persisted until her dismissal from hospital on the seventh day. Her condition on coming out was considerably worse than when she went in. I was informed by her that, out of the eleven patients in the ward where she lay, she was the only one, she was jokingly told, who had not had the distinction of being curetted more than once. The others had gone through two, three, or even four campaigns of curetting, and she was promised by them a speedy return. After she came out she rested in bed, and with local treatment was able to return to her former occupation of waitress.

The curetting of the virgin uterus is a thing apart. It appears to me as a routine to be a most revolting practice, and, on such slight grounds as instanced by Dr. Herman, one to be severely condemned.

Queen's Park, Manchester.

ALEX. FRASER, M.D.

A CASE OF HYDATIDS OF THE RIGHT OVARY.
The patient, aged 58, had during the last ten years lived in Italy, but prior to that she had lived in New Zealand. She had had two children and only ceased menstruating four years ago. At the menstrual periods she had never lost much.

About eight years ago she detected a small lump in the centre of the lower abdomen and twice she sought special medical advice regarding it. Those who saw her on these occasions and advised that it should be left alone no doubt considered, as I myself did, that the tumour was a fibroid of the uterus. Since she first observed the lump she has complained occasionally of a feeling of pressure on the bladder and of frequent desire to pass water. She consulted me because she had for eight weeks experienced more discomfort about the bladder. Apart from occasional backache she had practically never complained of any pain.

In the hypogastrium and extending farther into the left than the right iliac region was a very firm and somewhat ovoid swelling. It was not tender to the touch, and on bimanual examination it appeared to be uterine as the slightest movement of the abdominal swelling moved the cervix uteri immediately, and no portion of the body of the uterus was distinguishable from the tumour. It was quite evident, however, that the greater portion of the right half of the tumour was cystic, and on this account I strongly advised that the growth should be removed.

On November 2nd I opened the abdomen mesially. The tumour was so covered by bowel, omentum, and bladder, and was so very intimately incorporated with these structures and with the uterus, that the non-uterine character of the growth was only revealed as I freed these structures. The tumour then presented the appearances of a dermoid of the right ovary, and its exact nature was only revealed when it was laid open after the operation was completed. The tumour was of about the size of a full-term fetal head, and was crowded with the so-called daughter and grand-daughter cysts.

Hydatid cyst of the ovary is a great rarity. The tumour was not very large, and it evidently had grown very slowly. It, like other cysts of the ovary, had contracted firm adhesions with bowel, omentum, bladder, and uterus, without there resulting therefrom any very well-marked disturbance. Hydatids are not uncommon in Australia, but as far as I have been able to gather they are, comparatively speaking, rarities in New Zealand.

JAMES OLIVER, M.D. Edin., F.R.S. Edin.,
Physician to the Hospital for Women, London.

DIACHYLON AS AN ABORTIFACIENT.

THERE is some reason to believe that diachylon is now being used to a considerable extent in the East End of London as an abortifacient. Recently several cases have come to my notice in which puzzling symptoms following abortion were traced to the use of diachylon. Naturally, patients under such conditions are not likely to be frank in their statements, and the doctor is greatly hampered in arriving at a diagnosis. This is neither fair to the doctor nor the patient. The medical man is not given the chance of doing himself justice as a clinician, while the patient's sufferings remain unrelieved. I therefore feel that it is expedient to draw attention to the fact that this practice is becoming more prevalent in the metropolis. In the blue line on the gums we have fortunately an obvious and reliable sign which should always be looked for in suspected cases. There is an impression among some medical men who have given the subject little attention that the blue line requires some time for its development, and that it is not likely to be present if diachylon has been taken for a short period only. Experience, however, shows that in all cases of plumbism from the ingestion of diachylon in which severe symptoms appear, the blue line is almost invariably present, and is often very distinct. As has been pointed out before by several observers, diachylon is a particularly insoluble lead compound, and seems to be absorbed very slowly from the alimentary canal. The following three cases, about which I happen to have a few notes, may be of interest in this connexion.

CASE I.

MRS. H., married and mother of a numerous family, came to me on April 25th, 1908, complaining of severe pains in the abdomen. She had missed her periods for two months, and

admitted having taken some steel and pennyroyal pills. She was given a sedative, and told to keep in bed for a day or two. On May 13th she was called to see his room, and found that she had aborted, expelling a three months fetus. The secondines did not come away at the time, but were expelled on May 15th. Up to this point I considered the outlook very favourable. The patient's sister, however, who happened to be in the room, informed me that she herself had recently miscarried after taking some diachylon which she purchased in a shop and swallowed in the form of pills. On the patient's look at the patient's gums, and to my surprise I found that she had a well-marked blue line. She admitted having also taken a few diachylon pills. In the subsequent history of the case the pernicious effects of the drug soon became evident. The woman suffered from severe attacks of vomiting and abdominal colic over a period of six weeks. During this time I was called to her on two or three occasions at night, and had to administer morphine and opiates to relieve the intolerable pain. Her expression was anxious and her complexion sallow. There was obstinate constipation throughout. The symptoms of lead poisoning were the only sequel of the miscarriage; there was no pyrexia, pelvic tenderness, hæmorrhage, or foul discharge from the vagina. The treatment consisted in the administration of magnesium sulphate and opiates. The patient was kept in bed on a milk diet. Potassium iodide was given for three days in the second week, but as it appeared to aggravate the symptoms it was discontinued. The patient finally made a slow recovery.

CASE II.

Mrs. P., a mother of several children, came to my surgery on June 27th, 1908. She complained of pains in the stomach and pains in passing urine. She stated that she had suffered in this way for three weeks, and had been attended by a doctor who thought at first that there were some symptoms of enteric fever, but subsequently changed his diagnosis to that of "floating kidney." In reply to my questions she said that she had attacks of vomiting, with pain, but no diarrhoea. A certain reserve on the part of the woman led me to examine her gums, where I found a well-defined blue line. She then confessed that she had had a miscarriage four weeks previously, for which she had taken some diachylon made into pills. She was not at all surprised when I told her that her present symptoms were due to the drug, but said that she did not tell the first doctor who examined her anything about it as she had not asked her. She was given a mixture containing tinct. chloro. et morphinae to relieve the pains, and was told to take Epsom salts every morning. Improvement was rather slow. The urine, examined on August 5th, was found to be markedly albuminous. Being now free from attacks of colic, she was given potassium iodide in a mixture to aid the elimination of lead, and subsequently a mixture of liq. ferri perchlor. with liq. ammon. acet. for the anæmia and albuminuria. I saw her again in September, when she appeared to be doing well; the albumen had disappeared from the urine.

CASE III.

Mrs. M. H., aged 37, a mother of six children, sent her sister to me on December 10th last for a bottle of medicine to relieve pains in her stomach. The history was that the patient had miscarried some three weeks previously, that living a considerable distance from my surgery she was attended by a nearer doctor, who said that everything was all right, but that the retention of removal from one house to another, and possibly a cold, had brought the pains back again. My suspicions being aroused, I advised that, if possible, the patient should come and see me herself. This she did two days afterwards, and on inspecting the gums I found a well-marked blue line. On being questioned the patient stated that she had been taking somebody's female pills, but on my asking her if that was all she took she admitted that she had taken some pills which another woman had given her, and which had been made by the woman herself from some substance like soap. The symptoms were vomiting and attacks of abdominal pain. She had the same dazed, sallow, and anæmic look which was noticeable in the other two cases quoted. This patient is still under treatment.

In conclusion I wish to say that I have been greatly aided in coming to a correct diagnosis, particularly in the first case, by the perusal of the articles which have appeared on the subject in the BRITISH MEDICAL JOURNAL during the last few years. I have since had occasion to consult them several times for the elucidation of some obscure points in the symptomatology and for suggestions about treatment.

London, E.

EDMUND HAY, M.B., C.M.

RECTAL INJECTION OF BROMIDES IN
PUERPERAL ECLAMPSIA.

SEEING the letter of Dr. Alfred E. Townley in the JOURNAL of September 19th, 1908, brings to my recollection a severe case which I had during the deep snow of 1881 in a primipara. The convulsions came on before delivery, and continued for nearly two days after. The head was

shaved, ice applied to the scalp, and chloroform was constantly administered, but nothing appeared to relieve until I injected per rectum potassium bromide, gr. xxx, with chloral hydrate, gr. xxx. This I repeated four hours afterwards. Soon after the convulsions stopped, and she made a good recovery. Hydrate of chloral by enema is advised in Swayne's *Obstetric Aphorisms*, fifth edition, 1871, and about that time, whilst a student at Guy's, I heard potassium bromide suggested as an enema.

COVENTRY AND WARWICKSHIRE HOSPITAL.

A CASE OF AUDITORY VERTIGO: CURE BY OPERATION.

(Reported by F. FAULDER WHITE, F.R.C.S., Honorary Surgeon to the Hospital.)

The patient in the following case, a man aged 35, was admitted to hospital under my care on June 4th, 1908. He said he had had a running from the left ear for many years. Three months before admission he had suddenly become helpless from extreme vertigo while sitting at supper. He was very sick. Similar attacks recurred, becoming more frequent as time went on, until he was never sure of himself. He noticed that any exertion brought on an attack of vertigo. These attacks were often accompanied by vomiting.

State on Admission.—The man could not walk without staggering. He was quite deaf on the left side. The left ear was somewhat offensive in odour, and there was a minute central perforation in the membrane.

Operation.—On June 7th the membrane and malleus were removed through the meatus with a portion of the outer attic wall. Some carious bone was also removed from the walls of the middle ear. The parts were well cleansed with irrigation and attic mops, and a tympanic tube was left in the ear.

Progress.—For some days after the operation drops of chloroform solution were poured into the ear from time to time, but irrigation was not commenced before the fourth day. Some headache and giddiness were complained of at first, and antikamnia was prescribed.

Result.—There was steady improvement from the first, and no vomiting or severe vertigo occurred after the operation. He was transferred to the out-patient department on June 27th. The ear was sweet when he left off attending. Since then I have received the following letter from him; it is dated September 3rd: "I am very much better now. I am not suffering from giddiness up to the present. I thought a many times I would like to write to you to say how grateful I am." Three days later he cycled several miles to see me. He looked well, and said he had not felt giddy for some weeks. There was a slight discharge from the ear, which was without odour.

REMARKS.—I should not perhaps have reported this case but for the fact that two fatal accidents have recently been attributed to auditory vertigo. Some people have the idea that this trouble is necessarily hopeless; but, although a severe case, the above is one of many in which giddiness has passed away after disinfection of a diseased ear. Ear disease is most common, and vertigo may suddenly supervene. It follows that no one with ear disease should be allowed to drive a railway engine or motor car.

THERE are many who consider that the commercial strength of any seaboard country is best gauged by its shipping, and medical men interested in the subject will find a comprehensive review of it in the issues of the *Shipping World* for January 6th and 13th, the account being illustrated by an immense variety of photographs. Statements as to the shipping power of various countries are often misleading owing to registered tonnage alone being considered; but this error is avoided in this review, actual carrying power, not mere tonnage, being the unit of comparison.

Reports of Societies.

THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Friday, January 15th, 1909.

Sir PATRICK MANSON, K.C.M.G., President, in the Chair.

The Parasite of Kala-Azar and Allied Organisms.

Captain W. SCOTT PATTON, I.M.S., in a paper on this subject, said there was still much difficulty and doubt as to the cycle of events in the life-history of the parasite of kala-azar and those of the other closely allied organisms which were associated with Oriental sore and infantile splenomegaly. In all probability these were different species of the same genus. Christophers had shown, contrary to general belief, that the genus to which they belonged was not *piroplasma*; indeed, there was insufficient evidence that they could be regarded as a distinct or a new genus. Major Rogers had made an important contribution to our knowledge of the Leishman-Donovan parasite when he showed that in sterile citrated splenic blood the organism developed a flagellated form, but its morphology indicated that it was not a trypanosome. At no stage of the life-cycle did its appearance suggest a close relationship to any of the various phases of trypanosome metamorphosis. It was more nearly related to the familiar entozoan of the house fly, *Herpetomonas muscae domesticae*. Several of the stages of this organism were so closely allied to those of the kala-azar parasite that there could be no doubt of their affinity, and an exact knowledge of the life-history of *Herpetomonas* was essential to the study of the Leishman-Donovan parasite. Many erroneous impressions as to the morphology of *Herpetomonas* had gained credence. If carefully tested it would be found that the statement that it had two flagella (which was supported by the authority of Prowazek) was untenable. The double appearance, remarked by that observer, was due to fission, which took place during one of the earlier stages. Actually, there were three main periods in the life-cycle, the pre-flagellate, flagellate and post-flagellate, but there was no clear dividing line between them. The organism in the pre-flagellate stage, which was seldom seen, was found only in the upper part of the intestine; and it was then a round or oval body of 5.5 μ in diameter, with blepharoplast, small nucleus, and granules. In the flagellate stage a single stout flagellum developed from the proximity of the blepharoplast, and gradually elongated. There was a large central nucleus, with a clearly marked rod-shaped blepharoplast. At this period the organism divided by longitudinal division, and fission also took place lengthways through the flagellum. Large numbers of parasites in this stage of development could be found attached in palisades to the epithelium of the hind guts of flies; here, however, they lost their flagella, and in this post-flagellate stage became small rounded spheres which divided again by simple fission. As to communication of the infection in insects, infected flies were extremely prevalent in butchers' shops and at meat stalls, and he thought that transmission took place by healthy flies sucking up the organisms which had been deposited on the meat with the contents of the intestine. Another species of *Herpetomonas* which infested bugs was even more closely allied to the pathogenic agent of kala-azar than the *Herpetomonas* of flies. The first periods of the life of this parasite were passed in the crop and mid-gut, and at this time the organism was practically identical with the Leishman-Donovan body. Division took place here also by longitudinal fission, but in this instance four young unflagellated organisms resulted, flagella being afterwards pushed out from the body protoplasm. Bugs could frequently be seen with their proboscides plunged in the excreta of other bugs, and no doubt transmission took place in that way. His published description of the development of the parasite of kala-azar in the bed bug, *Cimex macrocephalus*, showed that it was not a sporozoan. It was a true flagellate, a *Herpetomonas*, and there were at least three pathogenic species: *H. donovani*, which was responsible for kala-azar, *H. infantum*, for infantile splenomegaly, and *H. tropica*, for Oriental sore. His

experiments in inoculating dogs with kala-azar had given results entirely different from those of Nicolle. The whole question was extremely complicated, and not the least of the difficulties was the fact that in bugs and blood-sucking flies of all descriptions a large variety of intestinal flagellates were so frequently parasitic that infection by them might almost be regarded as normal. Some of these forms closely resembled stages in the development of pathogenic protozoa, and they gave rise to endless doubt and confusion.

Dr. SAMBON agreed that the double flagella were division forms. The reason that the pre-flagellate stages were rare was that they could be found only after recent suction of blood. Was it not possible that there was sexual transmission also—such, for instance, as occurred in *Metaphagus ovinus*, in which an ookinet passed to the ovary? In blood suckers the life-cycle was more complete, and there was a sexual form of reproduction; in non-blood suckers the life-cycle was modified and multiplication was by schizogony.

Dr. Low said it was by no means clear that the parasite of kala-azar was a *Herpetomonas*. The *Herpetomonas* had no sexual stage, but the fact that the organism of kala-azar was intracellular and passed through a bug suggested a sexual stage.

Sir HAVELOCK CHARLES said that during a considerable experience in Persia he had seen a great deal of Oriental sore among camel drivers, but he never saw a case of kala-azar. On the contrary, in Lower Bengal, where there were no camels, kala-azar was, of course, very prevalent.

Dr. WENYON said that a hard and fast line could not be drawn between *Herpetomonas* and trypanosomes. Many varieties of trypanosomes had stages which closely resembled *Herpetomonas*. *T. theileri*, the well-known parasite of South African cattle, was an instance, and another illustration might be found in a trypanosome of snakes in which both forms were seen. The French Commission now investigating sleeping sickness had shown that some trypanosomes, after passing inside the proboscides of mosquitos, might assume *Herpetomonas* forms, and that they then attached themselves to the epithelium of the pharynx in exactly the same way as *Herpetomonas* did in the intestine. Might it not be that the influence of the blood of a vertebrate host tended to produce trypanosome forms; that of the intestine to produce *Herpetomonas*?

Sir PATRICK MANSON said that the life-history of the Leishman-Donovan parasite was not even approximately known. The figures shown by Captain Patton differed considerably from those of Leishman, which indicated division of nucleus, division of blepharoplast, but no division of flagellum. In the new forms, young flagella grew. The supposition that infection took place by an animal feeding on the excreta of its own species, assumed a fact that was contrary to the usual course of Nature. With regard to the differentiation of species, Novy had failed to infect a dog by the parasite of infantile splenomegaly; it remained healthy, but, after many months, when he killed it, he found the bone marrow was crowded with parasites.

Captain PATTON replied.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PATHOLOGY.

At a meeting on January 19th, Mr. S. G. SHATTOCK, President, in the chair, Dr. RONDONT recorded the histological examination of 3 cases of juvenile general paralysis, all the patients being hereditary syphilitics. The chief microscopic lesions consisted of a perivascular infiltration of lymphocytes and plasma cells, neuroglia proliferation, and neuronic degeneration. The author showed that the changes had not been limited to the cerebral cortex, but involved the basal ganglia. The President exhibited sections made by him from a piece of the aorta of King Menepthah which was sent to the Royal College of Surgeons by Dr. G. Elliot Smith, who unwrapped the mummy, on the instructions of M. Maspero, Directeur général du Service des Antiquités de l'Egypte. The mummy was found in the tomb of Amenhotep II, Thebes, and was that of the reputed Pharaoh of the Exodus. The sections showed the picture typical of senile calcification of the media, the wavy, parallel, elastic lamellae being perfectly preserved, and the interlamellar

¹ Scientific Memoirs, Government of India, No. 27.

material thickly strewn with particles of calcium phosphate. Dr. C. R. Box communicated two instances of idiopathic dilatation of the ureter without obvious mechanical obstruction. He stated that the ureter was rarely if ever dilated without a similar change in the renal pelvis, and the cases were no exception to the rule. In one of them chronic ureteritis and pyelitis were present. Possibly swelling of the mucosa, with perhaps superadded spasm, had during the acute stage been sufficient to obstruct the narrow extremities of the duct. The other case presented no signs of inflammation, and the narrator speculated whether the theory of mucosal hypoaesthesia, which Mr. Shattock had advanced to explain idiopathic dilatation of the bladder, was also applicable to a like condition occurring in the ureter. Mr. GIBSON recorded the changes observed in phosphorus poisoning in a rabbit, the observations being carried out at the laboratory of the London County asylums. Phosphorus had been administered to the animal by Sir Thomas Oliver in minute doses at meal times during a period of three weeks, and the brain, spinal cord, and sciatic nerves were sent to the laboratory. The staining methods employed were: Haematoxylin and eosin, polychrome blue, Nissl and Heidenhain's iron method. The following changes were noticed: The *motor cortex* showed changes in the shape, structure, and staining reactions of the cells. By Nissl's method many of the cells were well stained and appeared healthy. In marked contrast, however, to these cells were others which showed changes. Many of the pyramidal cells appeared larger and more circular and had a swollen look. Several of these cells were vacuolated, as many as half a dozen vacuoles appearing. Other cells were diminished in size with their outline blurred and indistinct, while others presented a wrinkled appearance with interrupted envelope. The nuclei in some cells were swollen and distorted; in others shrunken; in some displaced in position, in others not visible at all. In the swollen cells changes were noted in the Nissl bodies; instead of the customary mosaic pattern there was an appearance of fine dust or a homogeneous aspect. The apical processes of the cortical cells were very much distorted and twisted, giving them a corkscrew appearance. In the *spinal cord* appearances similar to those noted in the cerebral cortex were present. The degenerated or "shadow" cells were very numerous; and the same characteristic of a swollen badly staining cell lying beside an apparently normal one was noteworthy. Here and there in the substance of the cord minute haemorrhages were evident. Sections of the sciatic nerve were also examined but no changes worthy of note were detected. Dr. F. PARKES WEBER described the following cases: The first was that of a man, aged 35, who suffered from intense chronic jaundice due to carcinoma in the head of the pancreas. Ascites was present, and there was much fever. *Post-mortem* examination showed the presence of disseminated "islands" of necrosis in the liver, of the kind described by Curschmann in Germany (1899) and afterwards by Oertel in America. The central portions of these necrotic areas were often deeply stained with bile pigment, and in many of them a subsequent small cell infiltration had taken place. The present case differed somewhat from those previously described in that the jaundice was due to cancerous obstruction of the common bile duct. The second case was that of a man, aged 22, who died from acute hepatic atrophy, with clinical signs of icterus gravis supervening on those of ordinary jaundice. He gave a history of having been treated for a hard chancre not long previously. Messrs. C. E. WALKER and G. DEBAISIEUX described some observations made by them on the *Nucleoli in the cells of malignant growths*. In cancer cells the nucleoli, besides being more numerous than in normal cells, were very frequently irregular in shape. They multiplied rapidly, and the change in staining reaction when they passed out of the nucleus was altogether absent, or not nearly so marked as in the case of normal cells. An intermediate stage appeared to exist between normal and cancerous cells in simple inflammatory tissue. The interpretation with regard to the normal cells (where the phenomenon had been observed in hydra, spongiella, planarian worms, mammalian cells, and various plant cells) was that the multiplication and extrusion of the nucleus was dependent upon, and intimately connected with, meta-

bolism taking place in the nucleus. If this interpretation were correct, the nuclear metabolism in many cancer cells differed considerably from the normal, as it also did in the cells of inflammatory tissue, though in a less degree.

SECTION OF SURGERY.

At a meeting on January 12th, Mr. WARRINGTON HAWARD, President, in the chair, Mr. E. W. HEY GROVES read a paper, prepared in collaboration with Professor WALKER HALL, on the *Function of the colon* in relation to colic exclusion. Observations were made, more particularly upon three cases, in one of which a caecal fistula existed for a considerable period after the performance of ileo-sigmoidostomy, thus permitting simultaneous analysis of faeces passing from the ileum directly into the pelvic colon and those from the excluded gut. These analyses, and others of the faecal output at different periods after partial or total exclusion of the greater part of the colon, led to the conclusion that the lowest section of the large bowel was quite capable of performing alone the physiological duties of the whole colon. After "exclusion," water absorption was very nearly as complete as in the normal condition, and the irreducible minimum of nitrogenous waste in the faeces was not materially increased. Excision of the excluded part did diminish water absorption slightly, at any rate for a time; but since it appeared that perfect health was incompatible with the retention of a large cul-de-sac in which mucus and bacteria accumulate, and which might become a veritable cesspool by antiperistalsis from the rectum, it was essential either to remove the excluded part or to provide some means by which it might be flushed and, if possible, be allowed to atrophy. Mr. MACADAM ECCLES thought it might now be accepted that there was no physiological danger from the exclusion of the colon. Some abnormal excitement must be present for antiperistalsis to occur. It was better, therefore, to perform lateral anastomosis or "semi-exclusion," permitting some of the intestinal contents to reach the caecum and supply the requisite normal stimulus. Mr. MUMFERY did not agree with the views of the last speaker; Hertz and others had seen antiperistalsis in conditions scarcely removed from normal, and his own experiments on cats showed that antiperistalsis from the transverse colon towards the caecum occurred normally as the usual first result of entrance of food into the large intestine. Lateral anastomosis was unsatisfactory; he preferred division of the ileum, and of the colon above the anastomosis with formation of an iliac opening to drain the excluded gut. Mr. GROVES, in his reply, said that Mr. Lane had found lateral anastomosis unsatisfactory, partly for the reason that without stenosis of the old path beyond the new opening contents continued to pass that way and the artificial opening was practically useless. Mr. EDRED CORNER and Mr. MARTIN HUGGINS read a paper on *Obturator hernia*, based in part upon a case under their care and partly upon a collection of 250 cases from the literature. Their patient had been operated upon three times for intestinal obstruction due to nipping of a small piece of small intestine lodged in the right obturator canal. At the last operation a radical cure was performed by invagination and obliteration of the sac, using an incision in the pectineal region to supplement the abdominal manipulations. Of 970 cases of strangulated hernia admitted to St. Bartholomew's 2 only were obturator; of 1 026 at St. Thomas's 4 were obturator. Combining the figures this gave an incidence of 1 in 332 cases of strangulation. The occurrence was six times as frequent in men as in women. Child-bearing had influence only in so far as it conduced to rapid increase and subsequent loss of fat, since emaciation was the only constant antecedent. The youngest patient was 12, and the oldest 87 years of age, but it was very rare under 45. The obstruction was generally imperfect, and hence 80 per cent. were undiagnosed; attention was almost always called to the condition by supervention of obstructive symptoms. The small bowel was alone involved in most cases, but the ovary and tube might be. The right side was involved in 60 per cent., left in 33 per cent., and both in 7 per cent. The mortality was 33 per cent. The PRESIDENT remarked upon the frequent absence of classical signs of acute obstruction, emphasized the importance of rectal and vaginal examination, and asked

as to the frequency of the obturator pain so beloved of examiners. Mr. BARKER asked if it would have been possible to invaginate the sac without making the external incision. Mr. McADAM ECCLES mentioned a case he had recently operated upon, in which symptoms of obstruction had existed for a fortnight before the woman was brought to hospital; this delay was not uncommon in these cases, because only part of the lumen of the gut was involved; it was, in fact, a form of Richter's hernia. He thought it very doubtful if a lump could ever be felt in the thigh. Mr. GROVES asked if the sac passed through the same opening as the obturator vessels and nerve? Mr. CORNER, replying, said that pain in the course of the obturator nerve was rarely mentioned in the records; it was impossible to invaginate the sac from the abdomen alone; no tumour could be felt in the thigh in his case; the herniation undoubtedly occurred through the same canal as the vessels.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

At a meeting on January 5th, Dr. BURTON BROWN, President, in the chair, Professor CUSHNY, in a paper on *Tissue antiseptics with reference to animal infections*, said that since Lister had demonstrated how completely the activities of pyogenic organisms could be held in check by means of drugs, many attempts had been made to achieve the same result in diseases more strictly medical. In the specific fevers, and especially in tuberculosis, corrosive sublimate, carbolic acid, organic preparations of silver, and, more recently, formaldehyde, had all in turn been tried and abandoned; the host was too vulnerable, the parasite too resistant. There was, however, one group of diseases—for example, syphilis, malaria, and sleeping sickness—in which the malady was due to a parasite, less perfect in its adaptation to its surroundings, less resistant to drugs, and in these a greater success had been achieved. In some experiments undertaken to test the resistance of trypanosomes of sleeping sickness to arsenic, antimony, and bismuth, a proportion of 1 in 200,000 proved sufficient to banish the parasite. Thus 1 mg. of antimony destroyed the parasites in a 200 gram rat. Arsenic acted more slowly than antimony, and in the case of bismuth the damage done to the host was generally irreparable. The trypanosomes were not permanently destroyed, but in course of time returned. As often as they were banished they returned, and at shorter and shorter intervals. Finally, a race of antimony-resistant or of arsenic-resistant trypanosomes was produced, which, retaining this quality, could be propagated from rat to rat. The arsenic-resistant trypanosomes, however, were still susceptible to antimony or bismuth and vice versa, and in this might be found a modern indication for the use of old-time polypharmacy. In a patient treated at once with all the drugs available few trypanosomes would survive the combined attack. The trypanosome obtained from the rat which was resistant for any one drug, injected into a mouse, again became non-resistant to that drug. Dr. ALEXANDER HAIG, in a paper on *Salicylates as retentives of uric acid*, maintained that while large doses of the drug acted as solvents of uric acid, small doses acted as retentives. This retention was proved by the diminution in number of certain granules in the blood, and was invariably accompanied by a quickening of the capillary circulation. A measure of the time of the "capillary reflux," he maintained, was thus an accurate measure of the amount of uric acid in the blood. Dr. A. P. LUFF dissented entirely from the view that it was in any way possible to estimate the amount of uric acid in the blood by the appearances in the blood referred to. He had searched in vain through Dr. Haig's writings for an account of a single chemical estimation of the amount of uric acid. He denied that there was any proof at all that uric acid was a poison, or that the many symptoms attributed to it were due to it. Dr. H. C. CAMERON said that apart from the question as to whether or not the capillary reflux time was influenced by the amount of uric acid in the blood, there was so large a number of varying factors which did profoundly influence it—temperature, posture, emotion, the condition of the digestive organs, etc.—that he could not think that the results obtained could be reliable.

LIVERPOOL MEDICAL INSTITUTION.—At a meeting on January 7th, Mr. F. C. LARKIN in the chair, Dr. SMART reported a case of *Reinfection by syphilis* in a patient, aged 30, who first acquired syphilis in September, 1904. During the next year he had three courses of treatment by mercurial inunction, each extending over a period of six weeks, the first and last course being carried out at Aix-la-Chapelle. This attack was characterized by marked pigmentary skin lesions. On January 1st, 1906, he was again exposed to infection, and on the 26th he developed a hard chancre, the diagnosis being confirmed at Aix-la-Chapelle, where he was sent for further treatment. Mr. THRELWALL THOMAS read a note on a case of severe *Trigeminal neuralgia* treated by removal of the Gasserian ganglion. The patient, a man aged 58, had suffered from neuralgia for sixteen years. All the usual medical remedies had been resorted to but with no benefit. Cushing's operation was performed last June. The ophthalmic nerve was not removed. He has remained quite free from pain since. There is, however, distinct sensation over a large area supplied by the superior maxillary nerve. Dr. H. H. CLARKE, in a note on the differential diagnosis between human and bovine tuberculosis, said he had tried in six of his own cases the modification of Pirquet's cutaneous reaction as suggested at the last international congress. He considered that his results justified an extended trial of this method. Mr. R. W. MURRAY read a note on the after-results of 217 operations performed during the past three years for the radical cure of inguinal, femoral, and umbilical herniae. No recurrence had taken place in any patient under 40 years of age. Neither truss nor any other support was worn after the operation. The author considered the sac the essential cause of the hernia, and its complete removal was a particular feature in all the operations. Dr. W. B. WARRINGTON read a paper on the natural history of cirrhosis of the liver with reference to the value of the *Talm-Morison operation*. He considered that the disease could be distinguished from other morbid conditions which clinically it partly resembles, such as syphilis, chronic perihepatitis, and peritonitis. True cirrhosis is a rapidly fatal disease when symptoms have developed themselves, and the utility of the operation is doubtful.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a meeting on December 16th, 1908, Dr. P. BOOBYER, President, in the chair, Dr. JAMES WATSON read a paper on a case of *Epiploecy* and aseptic drainage by a modified method, for liver ascites. After reviewing the history of the operation suggested in this country by Drummond of Newcastle, and afterwards performed by Mr. Rutherford Morison, and independently by Chiazzi of Bologna, he explained that its object was to relieve the portal obstruction occurring in cirrhosis by a collateral circulation established in the omentum, which was stitched to the abdominal wall. Drainage was not essential in every case, but in the case of a woman of 27 who had come under the speaker's care in hospital, the patient's condition was so bad on the day fixed for operation (at her earnest request) that drainage was brought about first. Her condition, however, allowed the suturing to be also carried out successfully, and she progressed satisfactorily till the eighth day. Her mental equilibrium had never been altogether satisfactory before the operation, and she became excited and screaming on the ninth day, and died comatose on the tenth. The amount of ascitic fluid secreted decreased rapidly after operation, becoming practically nil within three days of it. A limited *post-mortem* examination showed the liver to be extensively diseased, and microscopic sections shown by Dr. Watson and microphotographs by Dr. J. Millar showed the glandular tissue to be reduced to a minimum. The speaker would regard the condition of the liver and the ascites as attributable to some fairly acute toxæmia, for the more acute symptoms dated back to an attack of diarrhoea, faintness, failure of vision and memory attributed to a meal of strawberries and cream about four months previous to her death. The President alluded to the *post-mortem* appearances of Dr. Watson's case. Dr. WEBBER and K. BLACK criticized the value of this as a remedy for ascites, and regarded the observation of the excretion of urine and ascitic fluid subsequent to the operation as inconclusive in consideration of the small quantities.

of fluid administered. Dr. A. J. SHARP asked for information as to the presence of leucin and tyrosin in the urine, and compared the case to acetonaemia proving fatal after operation and anaesthesia. Dr. WATSON, in his reply, pointed out that the marked reduction of the ascites within two or three days after operation could not be attributed to the development of new vessels. He would rather compare it to dropsy, which in the light of experimental evidence was much more due to toxæmia than to obstruction. Mr. H. B. TAWSE showed specimens of rhinoliths from three different cases, and commented on their pathology, and Dr. J. WATSON read notes of two cases of intestinal obstruction treated by bowel drainage, and showed a specimen from one case which proved fatal.

NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.—At a meeting in Manchester on January 15th, Dr. A. J. WALLACE (Liverpool) in the chair, Professor LORRAIN SMITH and Dr. W. FLETCHER SHAW (Manchester) read a paper on the pathology of *red degeneration of uterine fibroids*. They had examined four specimens, three of which were associated with pregnancy. Staining by Weigert's fibrin method they found extensive thrombosis of the blood vessels in the red areas of all four specimens, and this they consider the essential and characteristic change. There was no evidence of recent or old extravasation of blood. The myomatous tissue was also in a state of atrophy and degeneration, being replaced by a homogeneous substance, which stained faintly with eosin. This form of necrotic softening was very common in fibroids, and further observation was necessary to show whether red degeneration ever occurred apart from such a process of necrosis. Excess of fat, as droplets and crystals, was also found. Two of the patients had presented toxæmic symptoms, and in each of these cases the authors found an active leucocytosis and bacteria in the tumours—staphylococci in one, diplococci in the other. Neither bacteria nor a leucocytosis was found in the other cases. Finally, the authors pointed out that redness depended upon Virchow's angiomatous degeneration, and might be present in such a degree that the tumour had considerable naked-eye resemblance to the true red degeneration. Drs. LLOYD ROBERTS, BRIGGS, DONALD, WALLS, FOTHERGILL, LEA, GRIMSDALE, and CROFT discussed the paper; and Professor LORRAIN SMITH, in reply, expressed his opinion that the bacterial infection was secondary to and predisposed to by the thrombosis; that the excess of fat was dependent upon arrest of absorption resulting from the thrombosis, and that pregnancy, by mechanically hampering the circulation in the tumour, and the puerperium, with its increased coagulability of the blood, were possibly predisposing factors in the causation of red degeneration.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At a meeting on January 8th, Dr. EDWARD SERGEANT, President, in the chair, Dr. W. G. SAVAGE, in a paper on the *Scientific control of diphtheria*, pointed out that this disease stood out in striking contrast to some other infectious diseases, because its microbial origin had been fully proved and bacteriological diagnosis was sufficiently elaborated to enable the presence of the bacillus to be reliably and readily detected. He then submitted a scheme for its control. It included free and accessible bacteriological diagnosis by all medical practitioners, the usual procedure of notification, isolation and subsequent disinfection of every established case, the routine bacteriological examination of all immediate contacts and of some remote contacts, the isolation of all contact carriers either at home or in a hospital, and the discharge from isolation only after a sequence of negative examinations. He advocated institutional rather than home isolation; in Colchester the newly-erected administrative block of the small-pox hospital had been used for the isolation of contacts since 1906. In respect of contact carriers three "peas" were open: To do nothing; to isolate until free from infection; to limit their range of infectivity by preventing contacts from mixing with others as far as practicable, such as by prohibiting school attendance. To do nothing was as impossible as to allow a case of diphtheria to return to school as soon as the child was able to get up. It was important to have at least two, and preferably three, negative results before declaring the non-

infectivity of either a diphtheria patient or a contact carrier. In 1905 in Colchester if one negative result had been relied upon the error would have been 24 per cent., and if two negatives it would have been 5.3 per cent. The use of antitoxin as a preventive measure was both unnecessary and unscientific. The injection of serum did nothing to prevent the spread of infection, but rather, by inducing a sense of security and a selfish knowledge of self-protection, it would tend to check proper preventive measures being adopted. In the course of the discussion which followed Dr. SEATON said that he was afraid the proposals would involve a great deal of expense and would also interfere unduly with the liberty of the subject. He would like to have had some definite statistical evidence of the value of the scheme. Dr. GRIFFITH stated that no outbreaks of diphtheria had occurred in Hove since he had adopted a method of procedure similar to Dr. Savage's. He could not agree that antitoxin was not a prophylactic, but he considered that where it was given the case must be kept under observation. Dr. HOWARD-JONES considered that nasal as well as throat examinations should be made. He was strongly of opinion that antitoxin was a prophylactic. Dr. E. W. GOODALL was of the contrary opinion, and did not regard serum as a preventive. He considered that carrier cases should be dealt with on the lines suggested by Dr. Savage.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.—At a meeting on January 5th, Dr. MAY THORNE in the chair, Miss GARRETT ANDERSON read the notes of a case of *Chronic pancreatitis*. The patient was a married woman, aged 32, who had had no previous illnesses. Five months before admission to hospital she was seized with severe pain in the right hypochondrium. The acute pain lasted for two hours, and was succeeded by a dull aching pain lasting for two weeks. Three weeks before admission there was a second attack, and a slight attack occurred while the patient was under observation. Two days after the first attack she became jaundiced, and the jaundice persisted until death. When admitted she was very emaciated: the icterus was not very deep; the stools were soft and clay-coloured, and were not obviously fatty. There were occasional nausea and vomiting, with irregular pyrexia. There was a leucocytosis of 17,000, which increased to 50,000 before death. On examination of the abdomen the liver was found to reach to three finger-breadths below the costal margin, and was slightly tender. The gall bladder could not be felt. The diagnosis was thought to lie between obstruction of the common bile duct by gall stones and by malignant disease of the head of the pancreas. The emaciation suggested malignancy, while the apparent absence of an enlarged gall bladder was in favour of the other alternative. A laparotomy was done, and the bile ducts were found to be empty, while there was a hard mass in the region of the head of the pancreas, with enlarged glands in the portal fissure. The gall bladder was covered by the liver, and contained about 3 oz. of healthy bile. There were numerous adhesions about the bile ducts, the pancreas, the stomach, and duodenum. Permanent drainage of the gall bladder was established. After the operation the jaundice decreased, but marked anorexia persisted. A fortnight later the patient became suddenly collapsed, and there was hæmorrhage through the drainage tube. A week later there was bleeding from the mouth and nose, and the patient died. Calcium chloride and adrenalin solution were given during the last fortnight, but they did not check the hæmorrhagic tendency. Miss HAMILTON read an abstract of the *post-mortem* notes of the same case. A hard nodular mass was found in the head of the pancreas. The liver was enlarged, weighing $3\frac{1}{2}$ lb. It contained a few nodules resembling nodules of new growth, and in the upper part of the right lobe there was an abscess cavity the size of a hen's egg, containing bile-stained pus. Near the gall bladder the liver substance was broken down by hæmorrhage, and there was blood clot in the gastro-hepatic omentum and round the neck of the gall bladder. No biliary or pancreatic calculi were present. The spleen weighed 8 oz.; the other organs were normal. Microscopically the head of the pancreas presented no normal tissue, but showed a central necrotic area surrounded by a zone of fibrous tissue round which was an area of round-cell infiltration. The nodules in the liver had the same

structure. The body and tail of the pancreas showed an interstitial fibrosis. The islands of Langerhans were normal. The pancreatic duct was dilated.

Rebivius.

INTRACELLULAR ENZYMES.

Dr. H. M. VERNON has published a valuable monograph on *Intracellular Enzymes*, being the substance of a course of lectures given in the physiological laboratory of the University of London. He says: "I should scarcely have had the energy to collect and publish the material without the stimulus of an invitation to give these lectures." This is a sufficient testimonial to the value of the very few hundred pounds which the University of London has hitherto devoted to its highest function—the advancement of learning—an annual expenditure which soon, if not at once, threatens to come to an end owing to the poverty of the university and the ridiculous expenditure on the examination system. The State, which in Germany would give more than half a million a year to its metropolitan university, to London University gives a beggarly £8,000, excluding the grants to the incorporated colleges which cannot be used for the general purposes of the university. Work of the very highest value is done by the scientific men who occupy the chairs at the constituent colleges in the face of great difficulties. It is certain that these very difficulties act as an incentive to men of spirit, and that opulence of endowment and equipment generally leads to inglorious ease. In America, the land of great university endowments, this is prevented by a wise limitation of the salaries of the professors to very modest amounts, and a multiplication of posts in which each man can carry out independently his own line of work. How fruitful this policy has been is to be seen by the growing volume and importance of the American journals of physiology and experimental medicine. A most hopeful policy which the University of London can now take up, and is actually considering, is the raising of funds for the purpose of endowing research fellowships to be held at any of the laboratories of the constituent colleges, and thus stimulate in London the output of such work as that of Dr. Vernon at Oxford.

The intracellular enzymes differ from the exo-enzymes, such as are found in the secretions, by reason of the fact that they are bound up in the protoplasm of the cells, and, so long as the cells are alive, only exert their activity intracellularly. On the death of the cells the protoplasm disintegrates, and many of the constituent enzyme groupings split off and pass into solution. It is inferred, although absolute proof is wanting, that these enzymes were elaborated by and used during the life of the protoplasm. The fact that the secreting glands put out their enzymes into the secretions, which act at a distance, is greatly in favour of this view. It has been suggested that life is nothing more than the sum total of the activities of the enzymes contained within the living matter, but this simply pushes the difficulty further back and does not really bring us any nearer to the great mystery, for we know little more of the constitution of an enzyme than of living matter.

The first method to obtain intracellular enzymes was that of Buchner. He ground up the cells with quartz sand and squeezed the juice out by hydraulic pressure. Macfadyen and Rowland ground up the cells at the temperature of liquid air (-180° to -190° C.), at which temperature all chemical decomposition is stopped, and thus avoided the admixture of sand, which may absorb a certain amount of the ferments. Vernon finds that the extracts of ordinary minced organs yield ferments of maximal power in the shortest time if a mixture of three parts glycerine and two of water be used. The glycerine activates the zymogens. He has also investigated the daily yield of ferment of such an organ as the kidney when washed out with a stream of saline solution. When saline containing 2 per cent. NaCl is used the yield is almost nil, while chloroform saline causes an immediate and rapid setting free of the endo-enzymes.

Another method of study largely used is that of the

autolysis of the organs. Slices of an organ such as the liver are removed aseptically and kept at body temperature, or the minced organ is kept in the incubator and chloroform or toluol added to prevent or limit bacterial action. "Any or all the stages of (protein) digestion can be investigated by making kjeldahl determinations of the total nitrogen in the filtrate from samples of the press juice which have been precipitated by suitable reagents, and comparing them with the nitrogen in the unprecipitated juice." Hot trichloroacetic acid precipitates native proteins, 7 per cent. tannic acid proteoses, 40 per cent. phosphotungstic acid with 10 per cent. sulphuric acid proteoses, peptones, and di-amino acids, but not the mono-amino acids. In addition to acid and alkali acting proteoses which split native proteids, the juices of the organ obtained by pressure yield erepsin, which splits proteoses into amino-acids and ferments such as arginase, which can split individual amino-acids, and in particular one which can split ammonia off from amino-acids, and is perhaps identical with the urease which can be obtained from micrococcus urea by the simple method of extracting with water the alcohol precipitate of fermenting urine. Enzymes which hydrolyze nucleo-proteins can also be obtained from the press juices; these split nucleic acid into phosphoric acid and xanthin bases; also a guanase which converts the purin base guanin into xanthin; an adenase which converts adenin into hypoxanthin, and a xantho-oxidase which oxidizes these two into uric acid. A uric acid splitting ferment which breaks uric acid into urea and glycin also occurs. The yield of these proteolytic enzymes increases with embryonic growth and functional capacity, is diminished in hibernating animals, and in animals and children wasted by disease, and is increased in the mammary gland during activity.

The investigation of the endo-enzymes in disease opens up a wide field of research, which is just beginning to be worked. Brugsch and Schittenhelm have obtained evidence that in gouty patients the whole series of ferments connected with purin metabolism is enfeebled, and assert that when such patients are fed with nucleic acid its metabolism and the excretion of the uric acid formed is much slower than in normal people. In dealing with the fat and carbohydrate-splitting endo-enzymes, Dr. Vernon, among the many points of interest, here gives an account of those experiments of Harden and Young by which they demonstrate that the press-juice of yeast is activated by phosphates, and discusses the evidence in favour of the enzyme lactase being developed by feeding with milk animals which do not possess it. Confirmation is afforded of the assertion of Otto Cohnheim that pancreatic extract and muscle extract together have a powerful glycolytic action, and, therefore, of the theory that the pancreas by an internal secretion may activate the use of sugar by the muscles.

The later chapters deal with the oxidizing enzymes, the general constitution and mode of action of enzymes, reversible enzymic action, antiferments and the influence of antiseptics and temperature on ferment action. But enough has been said to show the interesting and valuable material which the author has gathered together in this volume, material which he has put forward in a particularly clear and easy style.

THE MARGINATE PLACENTA.

The marginate placenta was first described by William Hunter in 1794. The work before us (*Die Placenta marginata und ihre Entstehung*, by Dr. P. SPAMENI²) is a careful attempt to elucidate its origin and importance. Credit is due to the author for the trouble he has taken, but we cannot say that the result of his labour amounts to very much. There may be readers of this journal who know not what a marginate placenta is. For them we may explain that while the amnion can be stripped off a normal placenta right up to the insertion of the umbilical cord, the chorion as a rule is inseparably attached to the placenta at its edge. The marginate placenta is one in which the chorion is not attached to its edge; there is a margin, outside the attachment of the chorion. In width

¹ *Intracellular Enzymes*. By H. M. Vernon, M.A., M.D. London: John Murray. 1908. (Med. 8vo, pp. 252, 7s. 6d.)

² *Die Placenta marginata und ihre Entstehung*. Von Dr. P. Spameni, Professor und Director der Universitäts-Frauenklinik in Perugia. Mit 11 Abbildungen im Text. Berlin: S. Karger. 1906. (Sup. roy. 8vo, pp. 70.)

this margin varies from $\frac{1}{2}$ in. to 2 in. Outside the attachment of the chorion there is generally a ring of yellowish-white thick tissue, to which Busch gave the name of "annulus fibrosus." This ring is so constant that it is one of the most important signs of the marginate placenta. It is composed of decidual and chorionic tissues which have undergone necrotic change. Obviously, a marginate placenta is only found by those who carefully examine every placenta, and our author thinks that it is much commoner than is generally supposed. The first fact that he demonstrates is that a marginate placenta is generally a small placenta, and there is generally a small quantity of liquor amnii. The next is that it follows the law demonstrated by Matthews Duncan, which applies to twins, to monsters, and other departures from the normal in pregnancy, in being more common in first pregnancies, and in the later pregnancies of those who have had many children. Retention of chorion is commoner with a marginate than with a normal placenta, and so are its consequences, hæmorrhage and fever. Our author then quotes and criticizes the theories put forward by different writers to explain marginate placenta. Having done this, he expounds his own view. He points out that early in pregnancy the decidua serotina is cup-shaped; the ovum lies in the cup. There is no sharp distinction between decidua vera, serotina, and reflexa. As the ovum grows the sides of the cup are pressed outwards, until the decidua vera and reflexa are in contact. If the intraovular pressure is deficient the contact of the two decidua is imperfect. There is a circle at which the chorion laeve and decidua reflexa do not correspond to the chorion frondosum and decidua vera. Deficient extension of the uterus may also be due to undue rigidity of the uterine tissue, and such rigidity, in our author's view, is likely to be present in first pregnancies. This mechanical explanation of the production of placenta marginata is ingenious. But for practical purposes it does not seem worth much. If we accept it we remain still ignorant why the intraovular pressure is deficient, and why the uterus is rigid, and without knowledge of how these factors come into being, we can neither predict nor prevent the occurrence of placenta marginata. But the author is entirely satisfied with his theory. He says: "My conception of the origin of placenta marginata not only clears up all that is unknown, that on every other theory remains obscure, but finds evidence in its favour in all the facts hitherto brought forwards." We hope that nothing that our Boeotian intelligence has led us to say may disturb the author's happy delight in what he takes to be a complete solution of all difficulties.

OBSTETRICS.

We noticed the first edition of this work (*Introduction à l'étude clinique et à la pratique des Accouchements**) in our issue of July 25th, 1891. Since then, to the regret of all interested in obstetrical science, one of the authors, Dr. VARNIER, has passed away, we are sorry to read, "after many years of cruel agony." The book, we are informed, was long out of print, and when stray copies appeared in the market, they fetched almost incredible prices. Therefore, in 1904, a reprint was issued. Now we have a new edition. Some defective illustrations have been redrawn, and though some still do not satisfy Dr. FARABEUF, he hopes that he will be pardoned these on account of the good ones, which have been borrowed or imitated liberally, "ordinarily with acknowledgement of their origin, which is good, but not always, which is bad." The text has been added to, and some new illustrations inserted, but the size of the work has not been increased. Dr. Farabeuf says that he believes that Varnier would have approved these modifications, because his friends and pupils, who still exist, do so; but he accepts the sole responsibility. The work is not a complete treatise on midwifery. The subjects of which it treats are mentioned in the title page.

* *Introduction à l'étude clinique et à la pratique des Accouchements.* Anatomie—Présentations et positions—Mécanisme—Toucher—Manœuvres—Extraction du Siège—Version—Forcées. Principes fondamentaux d'obstétrique. Vérifiés, rectifiés ou établis à l'aide de l'expérimentation sur le mannequin naturel et de l'observation sur la parturiente. Par le Professeur L. H. Farabeuf et le Docteur Henri Varnier. Préface du Professeur A. Pinard. Nouvelle édition. Paris: Georges Steinheil, 1906. (Demy 4to, pp. 49.) Dessins démonstratifs de L. H. F., donnés avec les répétitions nécessaires, 375 figures. Fr. 15.

It is a book invaluable to the teacher of midwifery; of less value, perhaps, to the practitioner. The author says, "To critics, benevolent or malevolent, I replied and I reply: How have I always observed and experimented? On pelves of bronze or wood? Never in my life. I am not so stupid. I have observed, manipulated, and experimented on dead bodies preserved in glycerine and consequently kept supple; and, when possible, on the dead bodies of eclamptic patients who were in labour." These he calls his "natural mannequins." For an account of the general character and teaching of the book we will refer our readers to our notice of the first edition, for they remain practically unaltered. The illustrations are excellent; we know of none better. The letterpress exhibits the special merits that we are accustomed to in French literature—order, clearness, grace, and wit. It is a credit to the great country of which the author is one of the most brilliant sons.

Dr. P. BOUQUER begins his book, *Action de la contraction utérine sur l'œuf humain*,* with two propositions that seem to us contradictory. One is that when the uterus contracts, if the shape of the bag of membranes was ovoid the effect of uterine contraction is to make it spherical. This we think is correct; for the sphere is the shape in which the content is largest in relation to the superficies. If this is correct, the author's other proposition is not, namely, that if the bag of membranes is spherical, the effect of uterine contraction is to make it ovoid. No doubt the bag of membranes may pass from a spherical to an ovoid shape; but such a change accompanies uterine relaxation, not uterine contraction. The author draws what seems to us an irrelevant comparison with the crystalline lens of the eye. It seems irrelevant because the crystalline lens is not a hollow muscle, nor are the changes in its shape regulated by a hollow muscle. He speaks of the bag of membranes as being "inextensible, or less extensible than the lower segment of the uterus." But if it were inextensible its shape could not be altered at all. If it is only slightly extensible, the word with the negative prefix does not apply. The author's definition of "the lower segment of the uterus" is that it is "the part below the insertion of the utero-sacral ligaments." These ligaments vary so much in different subjects that this definition is not very exact. The author thinks that "primitive placenta prævia," that is, a placenta which was during pregnancy implanted over the os uteri, is quite exceptional; that in most cases of placenta prævia the placenta has been detached and pushed into the os uteri in front of the child. We agree that the effect of uterine action in placenta prævia is to detach the placenta and push it into the cervical canal; but we think that it is so because the placenta was primitively implanted over the os internum, which therefore could not dilate until part of the placenta had been detached. By reasoning which we cannot quite follow, the author holds that because ante-flexion is the natural shape of the uterus in most virgins, implantation of the placenta on the anterior part of the lower segment of the uterus is physiologically impossible. An ante-flexed uterus, he holds, is generally a healthy one. In placenta prævia, he says, labour comes on prematurely for a pathological reason, which is that the uterus is irritable, in consequence of endometritis; and, secondly, for a physiological reason—namely, inextensibility, owing to the low insertion of the placenta. The author theorizes ingeniously as to the part taken by different zones of the uterus in the first stage of labour. Space does not permit us to give his views in detail. He summarizes the matter as follows: "The true physiological wedge is the fetal wedge, which is alone capable of assuring complete dilatation—and not the bag of waters, which is only a dilator when the membranes are extensible." Perhaps our understanding is at fault; but this proposition seems to us to be contradicted by the frequency with which children are born in the amniotic sac. The author draws a distinction between painful and painless uterine contraction, but he hardly makes enough of the fact that the suffering which attends childbirth is due not only to the contraction of the uterus but to the stretching open of the soft parts; and it

* *Action de la contraction utérine sur l'œuf humain. Phénomènes passifs de la grossesse et du travail.* Par le Docteur P. Bouquer, Médecin de la Maternité de Brest. Paris: G. Steinheil, 1908. (Imp. 8vo, pp. 154, illustrations 45. Fr. 10.)

increases in severity in proportion as the parts which are stretched are richly supplied with sensory organs. The author is an original thinker, but it seems to us that he attaches too much importance to the bag of membranes and not enough to what German obstetricians have long described as the "fetal axis pressure" and the "form restitution force."

The work entitled *Consultations et formulaire de thérapeutique obstétricale*¹ is an excellent book for the French general practitioner. The various conditions that may call for treatment in the course of pregnancy, labour, and childbirth, both of mother and infant, are here described in short, pithy sentences. The authors' advice is, on the whole, sound and good. They do not lack courage, for they describe the intramuscular injection of mercury and intraspinal injection of stovaine as if these proceedings were as simple, safe, and easy as the administration of an enema or a bath. The volume is not illustrated. The English general practitioner has a choice among several books as good as this and adapted to English manners and customs, weights and measures; so that we can hardly advise him to get this, highly as we think of it.

PULSATING EXOPHTHALMOS.

Drs. DE SCHWEINITZ and HOLLOWAY, of Philadelphia, have lately brought out a book on the interesting subject of *Pulsating Exophthalmos*². The work is based upon an analysis of 69 cases, and is an elaboration of a paper read before the College of Physicians of Philadelphia in 1907. A lengthy table at the end of the book contains an analysis of 80 cases. Of these, 11 are regarded as doubtful or atypical, and are not used in making up the figures. The remaining 69 are classified thus: traumatic, 54; idiopathic or spontaneous, 13; tumour, 1; and cause not stated, 1. Of the 69 only 7 had both eyes affected, while of the traumatic cases 31 were males, 16 were females, and in 7 the sex was not stated. The greater number occurred between the ages of 30 and 40; the youngest patient was 4 years old, and the oldest 58. In the majority, the condition followed indirect injuries such as blows or falls, while gunshot or other penetrating wounds were responsible for a few. Of the idiopathic or spontaneous cases 70 per cent. occurred in women, and most of them were in the fourth decade of life; out of 313 reported cases the oldest was 81. The most frequent pathological condition found was a rupture of the internal carotid artery into the cavernous sinus, while tumours of the brain have in a few instances been known to have burst into the orbit.

As regards symptoms, exophthalmos, pulsation, and a bruit are the most marked, while the most common displacement of the eyeball is down and out. The subjective bruit is usually the first and most distressing symptom from which the patient suffers. Stasis and engorgement of the ophthalmic veins sometimes gives rise to the formation of venous swellings and tumours adjacent to the globe, usually situated in the upper and inner portion of the orbit below the arch, although they may occur at other parts. The masses are usually fusiform in shape, almost invariably painless, soft and compressible, while over them can usually be detected a thrill or pulsation. The lids are generally swollen, and the conjunctiva may be chemosed or injected, or ectropion may develop, while tortuous or dilated conjunctival vessels are usually present. The vision varies much; sometimes it is unaffected. The fundus may be more or less congested, with or without retinal haemorrhages. Naturally the ocular muscles are affected to a greater or less extent. Pressure on the carotid in most cases caused the bruit and pulsation to disappear, and the proptosis to be less marked. Occasionally a pulsating exophthalmos has been followed by a pulsating enophthalmos due to atrophy of the orbital tissues. The diagnosis of the disease is easy enough, but the underlying etiological factor is by no means so readily determined, and each case has to be considered on its own merits.

¹ *Consultations et formulaire de thérapeutique obstétricale*. Par les docteurs P. Budaux, Accoucheur des Hôpitaux de Paris, et P. Chantier, Chef du Laboratoire de la faculté à la maternité de Beaujeu. Paris: A. Maloin, 1908. (Poup. 8vo, pp. 320. Fr. 4.)

² *Pulsating Exophthalmos*. By G. E. de Schweinitz, M.D., Professor of Ophthalmology in the University of Pennsylvania, and Thomas B. Holloway, M.D., Instructor in Ophthalmology in the University of Pennsylvania. Philadelphia and London: W. B. Saunders Company, 1908. (Med. 8vo, pp. 124. 10s.)

The prognosis as regards life is good, but as regards vision extremely doubtful. With regard to treatment the following means have obtained favour. (1) Ligation of the larger blood vessels of the neck. (2) Operations on the orbit. (3) Compression of the common carotid. (4) Direct compression of the venous swelling in the eyelids and angles of the orbit. (5) Gelatin injections. (6) Rest and the administration of certain drugs. Double ligation of the carotid has frequently been followed by death, while the much less serious operation of ligation of the superior ophthalmic vein has given such good results that it is likely to supplant the more severe operation, though it has as yet been performed in comparatively few cases. In this series, compression of the common carotid was used in 12 cases, with cure in only 1. Gelatin injections were given in 3 cases and 1 was cured. The administration of potassium iodide and the instillation of adrenalin have given favourable results.

The book deals very thoroughly with the whole subject of pulsating exophthalmos, and in it the most complete account of the disease will be found.

DISEASES OF CHILDREN.

MEDICAL works of the epitome class usually leave much to be desired. As a rule many important points are omitted, and many of the statements made are too absolute, owing to the space not allowing of the requisite qualifications. To those who have neither time nor opportunity for consulting the larger treatises on children's diseases, Dr. APERT's *Precis des Maladies des Enfants*³ can be commended. It is one of a series of works on medicine edited by Drs. GILBERT and FOURNIER, and has been carefully compiled. Very few important points would seem to have been missed, and the information contained is both accurate and concise. We have noted very few points calling for adverse criticism, and of these most might be claimed as coming within the category of those on which individual experience has the right of expression. We will cite one or two instances: In the section on bronchopneumonia, Dr. Apert claims that it should be considered an infectious disorder, and that patients suffering from it should be strictly isolated. In this country we have hitherto been far from regarding cases of bronchopneumonia as coming under the class of truly infectious disorders, notwithstanding that there is a growing opinion in favour of their being treated by methods in which open air forms a more prominent feature than is at present usual. In the differential diagnosis between bronchiectasis and tuberculous cavitation, a distinction made by the author is that the former usually occurs at the base and the latter at the apex of the lung. Many authorities, however, believe that tuberculous cavitation in children occurs more often at the bases than at the apices of the lungs, and that this distribution is the more frequent the younger the child. In the etiology of chronic hydrocephalus, again, Dr. Apert would seem inclined to attribute the disorder to syphilis in a very much larger proportion of cases than most authorities would accept. An introduction by Dr. Marfan on the clinical examination of children adds to the value of the work. The book is daintily bound in limp red covers with white lettering, and the paper, print, and illustrations are all that can be desired.

Dr. DINGWALL-FORDYCE's book on *Diet in Infancy*⁴ is yet another on the present popular theme of infant feeding. The full title of the work would suggest that the author had propounded a thesis which he was prepared to defend by means of an essay. The work, however, deals with infant feeding in the ordinary way, and no attempt is made to substantiate the assertion that it is the essential introduction to the study of disease in childhood. In the preface the author modestly states that his little volume "pretends to no heights of eloquence, and no profound depths of scientific information." In spite of this, we may say that in many ways he deals with his subject in a more

³ Bibliothèque du Doctorat en Médecine. Publiée sous la direction de A. Gilbert et L. Fournier. *Precis des Maladies des Enfants*. Summary of Diseases of Children. I. Par le Dr. Apert. Paris: J. B. Baillière et Fils, 1908. (Post 8vo, pp. 532. 75 figures. Fr. 10.)

⁴ *Diet in Infancy. The Essential Introduction to the Study of Disease in Childhood*. By A. Dingwall-Fordyce, M.D., F.R.C.P.E., Extra Physician to the Royal Hospital for Sick Children, Edinburgh. Edinburgh and London: W. Green and Sons, 1908. (Cr. 8vo, pp. 184. 3s. 6d.)

scientific manner than is to be found in larger volumes of a more pretentious character. He has evidently studied the subject deeply, and his advice is, on the whole, sound and trustworthy. Exception may be taken to the dogmatic statement, more than once repeated, that peptonized or predigested food should *always* be given in cases of continued high temperature. Many healthy infants object to such foods at the start, and it would seem a doubtful policy to commence their administration at a time when, although the digestive powers are impaired, there is also usually a marked disinclination for food of any kind. The book is not an easy one to read, as the author has arranged his chapters in a series of numbered paragraphs. Many of these numbered paragraphs, again, are subdivided into others of a somewhat arbitrary character, headed by letters. The whole effect makes the book read somewhat disjointedly. At the end of the volume are eleven appendices, all of them of interest; but one or two, such as that dealing with the technique of the tuberculin test in cattle, seem out of place in a work intended for the busy practitioner.

Books written for mothers and nurses, and at the same time for members of the medical profession, are seldom likely to be entirely successful. It says much for Dr. Comby's methods that his little work, *Alimentation et Hygiène des Enfants*,⁹ written for such different classes of readers, has reached a third edition, and this in spite of his having hampered himself by arranging his subjects in alphabetical order. In addition to sections dealing adequately with the diet of infants and older children, there are others on baths, school hygiene, dentition, physical education, gymnastics, games, growth, walking, clothing, etc., most of which receive scant attention in the usual textbooks. In each of these the reader has the advantage of Dr. Comby's experience and advice expressed in language both terse and clear. In the section on the artificial feeding of infants, the dilution of cow's milk with "boiled or sterilized water is advised as being all that is necessary in ordinary cases. The proportions of milk to water recommended, however—namely, 1 to 1 at birth, 2 to 1 at 4 weeks, 3 to 1 at 8 weeks, and pure milk at ages over 8 weeks—are greater than in use here. But the experience of Dr. Comby, and his claims to speak with authority on such points are both indisputable, and his advice of such simple methods is strong confirmation, if any were nowadays needed, of the non-necessity of the complicated percentage systems of Roth and his followers. In France, indeed, and to a less extent in this country, the plan advocated by Parrot, and more recently by Budin, of giving undiluted cow's milk from birth, and simply increasing the quantity with advancing age, is finding increased favour. Budin, it is true, advised the use of sterilized milk alone, but it is a moot point whether sterilization is a necessary step in such a method, or even desirable as a routine practice. The only real essential probably is that the infant should be accustomed to the undiluted milk from the start. In a new section in the present volume the author strongly advocates the use of butter-milk in some of the intestinal disorders of infants and children: and it would seem that the subject deserves more attention than it has hitherto received in this country. Dr. Comby's work is worthy of the success it has attained.

In neither the title page nor the preface of Dr. SIMPSON'S little work, *A Guide to the Feeding of the Infant during the First Year*,¹⁰ is there any clue to the class of readers for whom it is written, and it is only from the elementary nature of much of the text that we gather that it is mainly intended for nurses and mothers. Written in a clear and simple style, it would seem well adapted for its purpose. It can be said that Dr. Simpson's advice is sound and judicious, and his somewhat arbitrary tone will only render his work the more useful to those for whom it is intended. In a section entitled, "Should Milk be Boiled before Use?" we read, "If we compare a number of healthy infants reared on unboiled milk and an equal number of healthy

infants reared on boiled milk, we find that the former class show a more uniformly high standard of good health and development." Now, whilst we believe this to be possibly true, and there is an increasing consensus of experienced opinion to support it, we would not have thought the fact so readily capable of demonstration as Dr. Simpson's assertion would lead us to suppose. It should not be forgotten, moreover, that many of the medical officers attached to municipal milk dépôts are of a directly contrary opinion. Dr. Simpson is sceptical as to the value of barley-water as an addition to cow's milk, and states that it should not be given during the first three or four months of life, owing to the starch it contains. But theories promoted on test-tube experiments should not weigh against extensive clinical experience, and it is only during such early months that any advantage is claimed for the use of barley-water over plain water in infant feeding. In later months it can advantageously be replaced by a more frank addition of some starchy material. Whilst denying the virtues of barley-water in the early months of infant feeding, the author states that the addition of lime-water renders the curd "much finer in quality, and therefore of a less irritating nature, than the firm, hard curd" ordinarily formed. Clinical experience here again is in favour of the use of lime-water, although test-tube experimental evidence may be wholly wanting as in the case of barley-water. We would ask the author, indeed, if he is prepared to demonstrate any notable difference in the clots formed when an acid is added to cow's milk diluted with equal quantities of plain water, barley-water, and lime-water respectively. The criticisms we have passed are of a minor character, and in no way detract from the favourable opinion we have formed of the little book.

That some elementary knowledge of the principles of medicine and surgery adds an increased interest to the work of nurses is not to be doubted. Many of the lectures they attend in the course of their training are devoted to elementary anatomy and physiology, and but few touch upon the clinical aspects of disease. The more enthusiastic nurses commonly supplement these lectures by consulting some of the ordinary textbooks on medicine and surgery, but even the smallest of these usually contain more information than is needful for nurses' purposes, or than their previous training will enable them intelligently to grasp. Under these circumstances, Dr. McCOMB'S book, *Diseases of Children for Nurses*,¹¹ may supply a want. In it the chief symptoms and complications in each of the ordinary diseases and the main points in the nursing are briefly and clearly indicated. The amount of information afforded, it is true, is not profound, but it may well serve as a basis for the nurse to build upon. In addition to those dealing with the separate diseases, there are preliminary chapters on peculiarities of children's diseases, and nursing in childhood, and concluding ones on infant feeding, therapeutics, and medical terminology. On the whole the matter would seem to have been well selected for its intended purposes. If a future edition is called for, however, it might be well to leave out such subjects as the methods of blood examination, lumbar puncture, fetal circulation, and many others, and to devote more space to the symptoms of the complaints. The illustrations add to the value of the book.

TUBERCULOSIS IN INFANCY AND CHILDHOOD.

The publication of the volume of essays by various writers, entitled *Tuberculosis in Infancy and Childhood*,¹² is opportune. The editor, Dr. KELYNACK, in an introductory chapter, says that the essays afford evidence that tuberculosis and a tendency thereto exist among the infants and children of civilized people to an extent not generally realized; the articles on Scotland by Dr. R. W. Philip, on Ireland by Sir John Byers, on France by MM. Calmette and Breton, on Germany by Professor Nietner, on Norway by Dr. Andvord, on Sweden by Dr. Barr, on Switzerland

⁹ *Alimentation et Hygiène des Enfants*. By Dr. Jules Comby. Paris: J. Rueff. 1908. (Cr. 8vo, pp. 505; 23 illustrations. Fr. 5.)

¹⁰ *A Guide to the Feeding of the Infant during the First Year*. By J. W. Simpson, M.D., F.R.C.P.E., Assistant Physician, Sick Children's Hospital, Edinburgh. Edinburgh: James Thin. London: Simpkin, Marshall, and Co. 1908. (Cr. 8vo, pp. 88.)

¹¹ *Diseases of Children for Nurses*. By Robert S. McComb, M.D., Assistant Physician to the Dispensary, and Instructor of Nurses at the Children's Hospital of Philadelphia; Assistant Physician to the Medical Dispensary of the Hospital of the University of Pennsylvania. Philadelphia and London: W. B. Saunders and Co. 1907. (Demy 8vo, pp. 450, 10s.)

¹² *Tuberculosis in Infancy and Childhood: Its Pathology, Prevention, and Treatment*. By Various Writers. Edited by T. N. Kelynack, M.D. London: Baillière, Tindall, and Cox. 1908. (Demy 8vo, pp. 389; 27 illustrations. 12s. 6d.)

by Dr. Carrière, and on New Zealand by Dr. Mason all tend to confirm this conclusion. The volume contains also articles on antenatal tuberculosis by Dr. J. W. Ballantyne, on tuberculosis of the various organs and systems by writers specially competent to deal with each, and a careful discussion of the diagnostic and therapeutic use of tuberculin in infancy and childhood by Dr. Clive Rivière. Dr. Leslie Mackenzie, Medical Member of the Local Government Board in Scotland, and Dr. J. H. Meikle, Medical Officer of Schools, Edinburgh, contribute a valuable joint article on school hygiene and medical inspection in relation to tuberculosis in children. They give first general statistics for Scotland, and then the results of special examinations of school children. With regard to the latter they make the following observations:

In these school investigations, the examination was limited to what was possible at school—physical signs and symptoms. None of the cases were verified by bacteriological examination. Allowance must, therefore, be made for non-tuberculous consolidations; but, whenever possible, the child got the benefit of the doubt, and only the marked cases were recorded.

But the probable prevalence of tuberculosis is not to be decided on such facts alone. Vast numbers of enlarged glands were found, some certainly tuberculous. Bronchitis we have already mentioned. Enlarged tonsils and adenoids were numerous. Malnutrition of every grade was common. Thus, many morbid conditions strongly predisposing to tuberculosis were present in a large number of children. All these point to the probable existence of "latent" tuberculosis—an unfortunate term meaning "active" tuberculosis, but not as yet to be diagnosed by ordinary clinical methods. (The word "latent" should be dropped; it is ambiguous.)

Medical inspection, the authors point out, is only the first step, and in cases of suspected tuberculosis it ought, they consider, to be followed up by "the detailed and prolonged observation that is possible only in an organized clinic." Diagnosis must be repeated and systematic, and each suspected case must be followed into its home. On this head they write:

If medical inspection is seriously to affect the prevalence of tuberculosis, the examination of the child must lead back to the examination of his whole environment—food, sleep, cleansing, family history, occupations of parents, health of other members, and, in general, every circumstance that lessens the likeness of the home to a well-conducted sanatorium. If every case of malnutrition is followed back to its home environment, the chances of infection will be diminished, and the medical inspector will know how to estimate the danger.

It is easy to foresee that special clinical provision must be made for the "observational" diagnosis of tuberculous cases, and diagnosis must be taken in the wide sense. It implies not merely the recognition of gross disease, which is the climax, but of all the malnutritional conditions that lessen the child's capacity for school work, or diminish its resistance to common ailments.

With regard to special methods of diagnosis, they say:

Wholesale use of tuberculin is out of the question. Equally so is Calmette's reaction, except under the most stringent hospital conditions. The risk of damage to the eye may not be great; but the risk is positive, not negative. The test would not normally be applied in an out-patient department, and in our opinion it ought not to be applied in schools. This assumes that the test is reliable—a point still unsettled. The eye is too tender and too precious an organ to be exposed to any avoidable risk. We think, too, that with more detailed clinical care, more extended scrutiny of glandular conditions, bones, joints, skin, teeth, tonsils, appetite, circulation, disease history, and family history, many marginal cases will come to light. It may be that minute doses of Koch's new tuberculin may become quite safe for diagnosis, but the use of it must be a matter for consultation with the parents. And none of these special methods can be applied profitably except in a regular clinic under skilled supervision.

Dr. Philip states (p. 198) that in Edinburgh, in the domiciliary visits paid by the Assistant Physician of the Royal Victoria Dispensary for Consumption, by the nurses, and by the ladies of the sanitary committee, particular attention is paid to the children of the household so that the unaffected may be separated from the affected as much as possible and affected children prevented from attending school. On the other hand, Dr. Philip is clear that a tuberculous child ought not to be kept at home, but sent to a school "run on physiological lines and presided over by teachers whose chief aim should be to assist in the development of the delicate frame"; and he is equally clear that no child or teacher affected with tuberculosis ought to be allowed to continue attendance at an ordinary school.

The volume, as we have said, is timely, and will well repay careful study, which will be much facilitated by an excellent index.

NOTES ON BOOKS.

THE volumes of the reprint on thin paper of the *Dictionary of National Biography* continue to appear with admirable punctuality, and since our last notice the alphabet has been traversed as far as Lluelyn, the last name in the eleventh volume of the reprint, and in the thirty-third of the original issue. The work suffers nothing from the thin paper, and in spite of the fact that the individual volumes of the reprint are larger, they are, on the whole, easier to handle, and perhaps in other ways more convenient to consult. Among the medical names in the eleventh volume is that of Lettsom, whose share in founding the Medical Society of London is commemorated in the course of lectures delivered annually before it. The tenth volume contains the biographies of John Hunter, of Anne his wife, whose poems and songs are enumerated, and of William Hunter, his brother, and of Edward Jenner, the latter by Dr. Norman Moore. The biography of William Harvey, from the same hand, fills nearly six pages in the ninth volume, which also contains a note on the life of Sir Charles Hastings, the founder of the British Medical Association. We can only again commend this great work of reference to every man of scholarly tastes.

SIR GEORGE WATT'S *Dictionary of the Economic Products of India* having been out of print, the author was requested by the Government of India to prepare a corrected and abridged edition of the work. The handsome volume on the *Commercial Products of India* which has recently appeared is the result. Every possible care has been taken to render this important publication as accurate and complete as possible. The compilation has been prepared under the supervision of Sir W. T. Thiselton-Dyer, Director of the Royal Botanical Gardens, Kew, aided by an advisory committee of experts, and the author has referred on special subjects to special authorities and made use of information obtained in India and systematically collected and indexed in the India Office. The "products" are arranged in alphabetical order and access to the contents of the book is made very easy and complete by means of page headings and marginal references and a copious and elaborate index. The work includes all sorts of commercial products—mineral, vegetable, and animal—foodstuffs, fibres, materials for arts and industries, intoxicants, narcotics, medicines, poisons, and so forth. Indeed, there does not appear to be any omission of any article of indigenous production sold in India or exported elsewhere, whether in raw or manufactured state. The descriptions of the source, preparation, and disposal, in trade and commerce, of the various materials dealt with are most ample, and abundant if not exhaustive references are given to books and papers relating to the subject under consideration. Trade statistics down to the year 1905-6 are given. The amount of information contained in this large, closely-printed volume is immense, and cannot fail to be of great interest and service to students of Indian products, whether for scientific or commercial purposes. Indigenous industries are described, as well as more recent methods of dealing with raw material introduced from foreign countries. Agriculture and livestock are fully treated, and long and learned discussions are to be found on matters of physiological and medical interest, such as the cultivation and use of opium, cinchona, cannabis, aconite, datura, abrus, erythroxylon, and many other plants employed as nervines, drugs, or poisons.

To the volume known as *Herbert Fry's Guide to the London Charities* we have drawn attention on many previous occasions. The edition for 1909 is the forty-fifth annual issue, and is edited by Mr. JOHN LANE. It is a compact handbook, giving in alphabetical order a list of all charities either established in or working from the metropolis, together with the names of their principal officials, their annual income, date of their foundation, their address, and the objects of each institution or association. The list is preceded by a general review of charitable enterprise in London during the year 1908, and by a few pages of notes on certain bodies which during the past year have for one reason or another come specially under notice. The book is to be commended as of decided utility.

¹ *The Commercial Products of India*. By Sir George Watt, C.I.E., M.B., C.M., LL.D. Aberdeen and Glasgow, F.R.C.L. London: John Murray. (Roy. 8vo, pp. 1197. 16s.)

² *Herbert Fry's Royal Guide to the London Charities*. Edited by John Lane. London: Chatto and Windus. 1907. (1s. 6d.)

MEDICAL AND SURGICAL APPLIANCES.

Simple Form of Vaginal Douche Tube.

DR. ALEXANDER DUKE (London) writes: A practical and useful form of vaginal douche tube is depicted in the accompanying illustration, made for me by Messrs. Howlett and Son, Charlotte Street, E.C. The stream of water is ejected in hollow cone shape, similar to others much more

expensive, and with the additional advantage there is nothing to get out of order, and the tube should last indefinitely unless broken by direct violence. The simplicity of the plan for obtaining the cone-shaped flush of water, combined with the moderate price asked, should recommend the tube. Rectal nozzles can also be made on the same principle.

PRAYER AS AN INSTRUMENT OF MURDER.

UNDER this heading an account of an attempt to organize the destruction of vivisectors by prayer, with extracts, was given in the *BRITISH MEDICAL JOURNAL* of January 9th, p. 112. The document, which was signed "M. Cowan," without date or address, and which bore no imprint, was handed to us by a member of the medical profession who is prominent in a line of research of the greatest importance to the well-being of mankind. It had been sent not to him but to one of his laboratory servants. Since then it would seem that "M. Cowan" has been inspired to send her appeal to some at least of the experimenters themselves. We therefore think it well to publish the whole document, with the covering letter, as it was placed in our hands:

Dear Sir,—I beg leave to introduce the enclosure to your notice, for, though a section of the community feel very deeply upon the subject therein treated, there is no desire to act harshly or hurriedly. They feel that very many err more through a want of thought and consideration for the real question at issue, than from any wish to do what is contrary to the instincts of justice and humanity.

This copy is therefore sent in time for you to weigh the pros and cons and to come yourself to a decision.

Yours truly,
(Signed) M. COWAN.

Some little time ago, in the coffee-room of a London hotel, I chanced to hear one of the party at a table close by narrate how he knew a person who was in the habit of praying from time to time for the death of one of our leading vivisectors; he said that always the man indicated had died. I tried to trace the speaker, but, as time had elapsed, did not succeed in doing so; I then thought, as I myself know of the efficiency of prayer, it would be well to try if this were actually so. I thought first of experimenting on Dr. Starling, but it seemed to me unfair to give such a stab in the dark without first letting it be known what was intended. It seemed also almost cruel, without knowing any of the surrounding circumstances, to select at random one from the large number of distinguished scientists on the medical lists.

It was therefore finally decided to make earnest prayer, giving much thought to the subject, that the Almighty, if the prayer were in accord with His will, would promptly remove the man most likely to cause future suffering to innocent subjects by his experiments. About a fortnight later one of our distinguished medical scientists dropped, and the newspapers were lamenting the loss to science of this vivisector and the discoveries he was just about to make.

Our Saviour distinctly states: "A sparrow falls not on the ground without our Father." If that be so, then He stands in the laboratory beside the operating trough. Without doubt, He is who so often gives an insensibility to the man enduring, which seems unaccountable to the operator. But does He protect the operator and the watching students from the hardening and vitiating effect of constantly participating in cruelty?

Vivisection is not a question of expediency, it is a question of right and wrong. What the Royal Commission decides, permits or does not permit, is of little or no importance in comparison with the will and mandate of a higher Power. The prayer of the child of God reaches further, is more searching in its effects than any enactment of the law can be. Not only does it enter the vivisectioning room, embracing all operations there, it is with the patients in our hospitals, and by the bedside of the poorest sufferer, and it will make its way into the garret or concealed chamber where the student, eager for knowledge and advancement, illegally tortures his helpless victim from day to day.

Let us not confine our prayer to our own country and our familiar surroundings, but let it include all kingdoms, peoples, and languages; France, Germany, Khartoum, India, America, or wherever there may be scientific experiment, experiments practised contrary to the will of our God.

If, as we are told, "the heart of man is deceitful above all things, and desperately wicked," it is conceivable that amongst all the thousands of medical men and distinguished scientists

there may be one individual who answers to that description. Is it not our duty to protect the general public from the evil influence of that one man? We owe it to our poorer neighbours, when we take them into hospitals principally supported by us and the handsome donations of our rulers, to ensure to them that unauthorized experiment, that is, experiment without the consent of the patient or his friends, be not practised there.

For many years, in fact since 1877, the subject of vivisection has been greatly and distressingly in my thoughts.

So difficult it is to understand how a God, such as we know our God to be, sympathetic, all powerful, and easy of access, does not interfere on behalf of His creatures, helpless and oppressed; but may there not in these cases be some ultimate advantage to the sufferer, in no way contemplated by the oppressor? If the Captain of our salvation was made perfect through suffering, if we ourselves must through much tribulation enter into the Kingdom of God, then, without doubt, we may hope that in cases of long and unmerited suffering, another and superior footing, in their future state, may be accorded to these animals.

If it be so, that the Almighty has vouchsafed to His followers the gift of prevailing prayer, let them use it. It is the prayer of the people of God, the followers of Christ, that must win the battle in the struggle against vivisection. When we pray, "Thy will be done," surely we allow that some one is to do it. Then let us not permit cowardice, or credulity in the belief of a great benefit to future generations, to restrain our prayers—a benefit to be won by the torture in the present of millions of our humble friends; to be won by the investigations of those who are impervious to all feeling of pity for the defenceless, helpless, and weak.

Altho' there are many Christian people who daily impetrate the Almighty not to permit any discovery of real value to be made by such cruel means, and this prayer has certainly not gone unanswered. Let us pray, then, not only occasionally or spasmodically, but, fixing the mind upon this subject, offer up our prayers morning and evening continually. Let us be particular only to ask for what accords with the will of God.

Who are the men to whom Christ says, "If ye shall ask anything in My name, I will do it"? Is it not those who have made a covenant with God by sacrifice (Christ's)?

Do these scientists expect us to believe all they tell us? Are they serious in asking us to trust them? "Surely they are not serious."

Let them take thought now, and be warned. It is not too much that we petition for. Who can tell if God will turn and repeat, that these men perish not?

God saw the work of the men of Nineveh that they turned from their evil way, and God repented of the evil that He said that He would do unto them, and He did it not."

Their fate is in their own hands.

M. C.

We may remind our readers that this letter and the accompanying exhortation to pray for the death of vivisectors were sent to a servant in a laboratory. That seems to us the only thing that gives it any importance. Vivisectors, of course, will only laugh at it; but it is conceivable that the document might have some effect on the minds of half-educated persons. We need not comment on the state of mind of a woman—for it has the marks of the sex of the author writ large upon it—who prays for the death of fellow creatures and invites other people to do likewise. We need only point out that the moral outlook of the thoroughgoing antivivisectionist is akin to that of the religious persecutor. In both is visible the same arrogant assurance that they are in the counsels of the Almighty, and that they have a direct mandate from Him to destroy any who differ from them in that belief. We venture to suggest to "M. Cowan" that it would be more charitable if, instead of praying for the death of vivisectors, she were to ask for the services of the Christian Scientists to charm away the sufferings of the victims of the scientific "torture" chamber. As we understand the teaching of Mrs. Eddy and her apostles, faith on the part of the subject of their "treatment" is not required; therefore their power should extend to animals as well as to human beings. This would at once be an opportunity of proving the non-existence of pain, without the anaesthetics of whose efficacy antivivisectionists profess to be sceptical, and would save the souls of the prayer-murderers from any danger of blood-guiltiness.

In the meantime we call the attention of "M. Cowan" to the fact that the only apparent answer to her prayers has come in the form of a donation to the London Hospital for the furtherance of medical research work. This reminds us of Mrs. Carlyle's story of the old lady who one rainy summer took part in a public prayer for fine weather. In the middle of the pious exercises a tremendous thunderstorm burst over the heads of the worshippers. This shook the faith of the old lady to such a degree that she exclaimed, "Oh, Lord, this is too ridiculous!"

LITERARY NOTES.

THE article which appeared in the BRITISH MEDICAL JOURNAL of January 16th, p. 165, under the title of The Great Plague of London, was contributed by Sir James Sawyer of Birmingham. We regret that, owing to a misunderstanding, his name was omitted.

A short time ago we quoted the well-known lines:

Perhaps it was right to disseminate your love,
But—why did you kick me downstairs?

After a good deal of trouble we found them attributed to John P. Kemble (1757–1823) in Cassell's *Book of Quotations*, by W. Gurney Benham. The lines are there given as follows:

When late I attempted your pity to move,
Why seemed you so deaf to my prayers?
Perhaps it was right to disseminate your love,
But—why did you kick me downstairs?

The source is said to be a comedy called *The Pencil*, produced on November 23th, 1788 (Act I, sc. 1). There is a footnote to the following effect:

This is Bickerstaff's comedy, 'Tis Well 'Tis No Worse, adapted and reset. The lines appear as above in *The Annual Register*, 1783, appendix, p. 201, among "Miscellaneous Poems," and are headed "An Expostulation"; also in the *Asylum for Fugitive Poets*, 1786, vol. 1, p. 15. In both cases the lines are published anonymously. It is presumed that John Philip Kemble was the author, but this is not certain. The lines were not in Bickerstaff's comedy as produced in 1770.

Isaac Bickerstaff was a real man, a short account of whose stormy career may be found in the *Dictionary of National Biography*. The name is best known to students of English literature as a pseudonym used by Swift in ridiculing the predictions of one Partridge, a London shoemaker in the early part of the eighteenth century, who professed to have the gift of prophecy. Out of Swift's papers on this subject grew the *Tatler*, in introducing which Steele adopts the name because it had "gained an audience of all who have any taste of wit." The difficulty of running familiar quotations to earth is often very great. Thus the saying that "Cleanliness is next to godliness," to which a Scriptural source has frequently been attributed, belongs to Charles Wesley; it occurs in a sermon on dress. Boswell tells the following story of Johnson:

When I once talked to him of some of the sayings which everybody repeats, but nobody knows where to find, such as *Quos Deus vult perdere, prius dementat*, he told me that he was once offered ten guineas to point out from whence *Semel insanivimus omnes* was taken. He could not do it; but many years afterwards met with it by chance in "Johannes Baptista Mantuanus."

The words occur in the First Eclogue of Mantuanus's *De Jovis Amore*, and the whole line is:

Id commune malum: semel insanivimus omnes.

Dr. Birkbeck Hill says the words *Quos Deus vult perdere, prius dementat* are probably a rough translation from a fragment of Euripides. Another oft-quoted saying, *Quantula sapientia mundus regitur*, is attributed to the Swedish Chancellor, Oxenstierna. As to this there is a note in Great Duff's *Notes from a Diary* (1886–1888), which well illustrates the difficulty of which we are speaking. The entry is as follows:

Byrne writes on her to-day's date [May 24th, 1838]:

"Do you recollect the hunt I had for the correct version of Oxenstierna's saying about 'the little wisdom with which the world is governed'?" Six various readings I had before me, each one endorsed by an extremely respectable authority, and your *Geflügelte Wörter* told me the original authority for it was *Lundblad's Svensk Plutarch*: so I searched, first at the Boleian. No! No Lundblad there. Then at the British Museum: some portions of the work, but not the one I wanted. Then, through a Swedish friend, in the Library at Upsala: no Lundblad at all. At last he ran it to earth in the Royal Library at Stockholm, and the correct version turned out to be *different* from every one of the six above referred to, and to run as follows:—
"An nescis, mi fili quantilla prudentia regitur orbis?"—(*Scensk Plutarch* II. Stockholm, 1826. Page 95.)"

Under the title of *A Collection of Contemporary Documents (MS. Eg. 2134) Relating to the Trial of Mary Queen of Scots, 1586* (J. T. Savage, Chatham Street, Ramsgate), Dr. Charles Cotton of Ramsgate has made a very interesting contribution to the history of the trial and death of Mary Queen of Scots. The documents, which are known as the Bardon Papers, were intended for publication sixty years ago, but drifted into the British Museum instead. How these papers got to Bardon, an old manor house in Somerset, is a mystery; but Dr. Cotton, who is connected by marriage with the Leighs of Bardon, suggests a probable explanation. The Leighs were an old Devonshire family, a branch of which settled at Bardon in the latter half of the sixteenth century, and were closely connected with a certain Robert Scudamore. If this Scudamore is the same person as the Scudamore who was Under Secretary of State at the time these papers were written, and lived in Walsingham's house, it is easy enough to see how they came to Bardon. Dr. Cotton says there is little doubt that the Bardon Papers passed from Scudamore into the hands of the first Leigh of Bardon about the year 1595, were brought to Bardon soon after, deposited with other documents in an attic, and left there till their existence was forgotten. Dr. Cotton does not claim to be an ardent supporter of the unfortunate Queen; he states the case in an impartial manner. There seems to be little doubt that the entire mass of evidence brought against Mary at her trial was forged by Elizabeth and her Ministers. Mary was not only dangerous because she stood in the way of the Reformation; she was likely to succeed to the throne of England very shortly, as her cousin was old, and Elizabeth's Ministers knew that their safety would end with her life. It was necessary to remove her; but this could not be done without a pretext, therefore the letters proving her implication with the plot against Elizabeth's life were forged, and she was tried and executed. At the trial not a single document was produced. Mary was condemned solely on copies of letters and depositions. She was never allowed to see either Babington or her secretaries, Maw and Curle, after their confessions implicating her in the plot against the Queen's life, though she demanded it as a right. No witnesses were present during the trial at Fotheringay, and at the Star Chamber at Westminster Mary was absent whilst the witnesses were examined. Of the two letters in the Bardon collection which purport to be from Mary to Babington only the first bears her signature, and this merely asks him to forward to her a packet of letters from France. The most conclusive proof that Mary knew nothing of an attempt to assassinate Elizabeth lies in the fact that neither in her letters to Mendoza and Paget, nor in the references to her letters to Charles Paget, Englefield, the Duke of Guise, and the Bishop of Glasgow does she ever allude to the possibility of compassing her cousin's death; and none of the notes and papers of the commissioners contain any reference to the fact that Mary knew her friends were plotting to kill the English Queen. It was not difficult to trump up a charge against Mary. Walsingham's spies were everywhere, in the Tower, in the seminaries abroad; the very clerk at the French Embassy entrusted to copy out Mary's ciphered letters was said to be in his pay. Whilst Mary was busy planning for her escape, the fact that Elizabeth's life was threatened was carefully hidden from her; Gifford did not tell even Mendoza of this part of the plot till the beginning of August, 1595, and by that time the game was almost up. At her trial she acknowledged that she had known something had been kept from her, as the conspirators knew she would never consent to it, and that her name might have been used without her knowledge, as indeed it was, in a way she little guessed at the time. For Walsingham and his creatures forged letters from her to Babington which drew forth from him all the details of the plot, including the assassination, and when they had all the necessary evidence to implicate the Queen, it only remained to arrest the chief conspirators and try Mary for her life. In the interest of historical truth, it is a great pity that the Bardon Papers have never been published, and it is to be hoped that Dr. Cotton, who has so ably brought the matter contained in these MSS. to the notice of those who are interested in all that concerns Mary Stuart, will not rest satisfied till he has published the full text.

ROYAL COMMISSION ON VIVISECTION.

FOURTH REPORT.

(Continued from page 164.)

We continue our abstracts from the evidence of which the minutes are contained in the fourth report of the Royal Commission on Vivisection, issued in December, 1907.*

Evidence of Dr. Henry Head, F.R.S.

Dr. Head gave evidence as to the relation of our knowledge of nerve diseases and experiments on animals. The dissecting room helped very little. The anatomist could not even say whether the biggest tracts visible to the naked eye conducted upwards or downwards. The beginning of our present knowledge came with Waller's discovery that a nerve degenerated when separated from its nutritive centre. This law was the direct outcome of experiments on animals, and its application to the brain and spinal cord was responsible for the greater part of the knowledge of the structure of the nervous system now possessed. But for Waller's law Gowers could not have used the injury in man to discover ascending tracts in the lateral column. But there was a great deal of dispute about them until Mott and others settled their anatomical connexions once for all by animal experiment. By experiments on animals a tract or set of tracts could be divided precisely; the animal was kept alive until degeneration had taken place, and was then killed. By suitable means the dead parts could be coloured so as to stand out clearly in the microscopical picture. The method by which these dead structures were made to show up clearly against the healthy parts was discovered by Marchi from experiments on animals. Waller's law and Marchi's method, applied to material obtained from experiments on animals and from disease or injury in man, were responsible for almost all our knowledge of the anatomical paths in the nervous system. Our present knowledge of the anatomy of the nervous system depended to an enormous extent on methods discovered from experimentation on animals, and in the utilization of these methods upon material derived from the results of disease or accident. For a knowledge of ingoing sensory paths, they were obliged to fall back mainly upon disease, because man alone could tell of his sensations, but disease produced irregular and diffuse destruction, and the most instructive conditions rarely came to *post-mortem* examination. Even here, when observation of disease on man started with a preponderating advantage, in that man could tell of his sensations, experiments on animals were necessary to supplement the rare opportunities offered by disease. On the motor side experiments on animals had the overwhelming advantage that the destructive lesion or the stimulus could be localized accurately, and observations could be made, under the direct conditions of experiment, time and place being convenient. Hughlings Jackson discovered by long and laborious observation that when certain parts of the surface of the brain were the subject of disease, certain movements were produced in the limbs. But these results remained a brilliant hypothesis until Hitzig in Germany, and Ferrier in England, showed by simple direct experiment that stimulation of the surface of the brain in animals produced movements of the limbs such as Jackson had described. In spite of a generation of clinical observation since that time, many important details of cortical localization remained undecided until Sherrington and Grünbaum's experiments on the anthropeid apes. It might be asked: Why not experiment on men who offer themselves voluntarily? The witness held very strongly that no man had the right to be the subject of an experiment unless the whole conditions surrounding the experiment were previously known as well as they could possibly be at the time. In his own case the most careful observations were made upon patients suffering from accidental injuries to nerves. Then an experiment upon himself was designed so that the question which could not be answered by these accidental lesions was put directly, and the answer given clearly. Every now and then, for the

relief of pain, man was operated upon under conditions closely representing those of animal experiment, as in the division of the posterior roots for pain and the operation of the removal of the Gasserian ganglion at the base of the skull for persistent neuralgia. The operation was brilliantly successful, and now that people were getting skilled the mortality went down every year. One particular case he had under observation now was done about 1897. The operation enormously improved the general vitality, because the patients had suffered from terrible pain over long years, and the relief often turned them into entirely different beings. It altered the appearance of the face, because one must divide the motor nerve for certain parts of it. It partly took away the power of movement. That side of the face was very nearly dead to all sensation, and the nutrition of the parts supplied by the divided nerve was somewhat affected. If one took care, in the present day, the eye was not affected. In the old cases the eye used to suffer a good deal. The mortality was high at first. Proceeding, the witness told the story of a small research, which illustrated the close interrelation between animal experiment and the utilization of the material obtained from disease. The problem was: Why did pain caused by irritation of some internal organ radiate on to the surface of the body or into the limbs, and why did these parts become tender? It had long been known that when an internal organ (such as the heart) was affected the pains were not always situated over its position; they seemed to go into other parts of the body. In consequence of the work of Dr. Gaskell, some suspected that this was the way in which the internal organs expressed themselves when they were diseased. Dr. James Mackenzie and the witness independently attacked the problem and examined for a number of years the actual facts as they occurred in patients in the hospital. They selected instances in which one organ, if possible, was affected. For instance, in such a disease as stone in the kidney, they watched the pain produced by the stone, and then saw the stone removed and the pain disappear, and by a series of observations, extending over a number of years, they determined that when an internal organ was affected in this sort of way, it expressed itself by pain radiating round the body, associated with areas of tenderness on the skin. So little had that any relation to anything that was known that most people doubted that these areas occurred. But throughout the whole research they were much supported by Sherrington's experiments on the distribution of the posterior roots. He found by experimenting that, supposing one worked out the parts supplied by one posterior root, it was found that they spread over the body and limbs, and were distributed in a sort of zone, like a half-belt round the body. The witness was in touch throughout the whole of his observations with Sherrington, who was at that time working out these zones, which were previously entirely unknown in animals; that fact made him certain that his observations on referred pain were correct, and enabled him to propound a set of figures, what might be called a map of the body. Sherrington carried on experiments on animals for some four or five years, and operated on a considerable number. He used monkeys and cats. Asked if the animal would be in a state of suffering on account of the operation, the witness said, Not in the least, except for possible post-operation discomfort. The whole point in the operation was that the animal should be as normal as possible, otherwise it was no good. Asked if the nerves would not come together again, he replied that arrangements were made that they should not, just as in human neurotomy. The Chairman then referred to what he thought a very cruel operation—namely, unnering a horse to make an animal which is lame in the feet insensible in the feet altogether, and asked if the operation could be done under anaesthetics if the veterinary surgeon performing it thought right. The witness said, Yes, perfectly well, and if it was done so that the nerve did not come together it would not be cruel in any sense of the word. Done on a horse not under anaesthetics, he did not think it would be excessively painful. Done extremely quickly it would be a momentary violent stab of pain, and then the thing would be over; but the only pain that could come in was when the nerve regenerated, not when the nerve was divided.

* London: Printed for His Majesty's Stationery Office, by Wyman and Sons, Limited, 109, Fetter Lane, E.C. And to be purchased, either directly or through any bookseller, from Wyman and Sons, 109, Fetter Lane, Fleet Street, E.C.; and 32, Abingdon Street, Westminster, S.W.; or Oliver and Boyd, Edinburgh; or E. Ponsonby, 113, Grafton Street, Dublin. (1908.)

If the nerve remained divided no pain could come in. Continuing his evidence as to the research, the witness said the next stage was to find out what happened if these parts that Sherrington had been working upon were irritated in man. That could obviously not be done by an ordinary experiment, but shingles, as was well known, produced the most violent irritation of the posterior root, the ganglion. By working on shingles and on the dead-house material microscopically, and using the method for colouring that had been discovered on animals, they were able to show that irritation of the ganglion was able to produce these zones on the body closely resembling, but differing on the other hand to a certain extent from, those obtained by Sherrington. At the end of this stage it was at once seen how little was known about the distribution of the nerves on to the surface of the body. Generations of anatomists had dissected the nerves of the human body, and it was thought they knew all that was to be known about their distribution. Yet when a workman came to the hospital, any physician or surgeon who was honest with himself, had to say his knowledge gained from dissection told him nothing with regard to the sensory condition of that man's hand. They were so impressed with the absence of knowledge on these points that they set to work first of all to observe what actually happened when by accident various nerves were divided. They began to suspect that there were certain laws underlying the whole thing which had never been formulated. But good as hospital patients were it was obvious that no working man could give the time required or the attention for a long and elaborate series of observations. Therefore, after they had made several hundreds of observations on ordinary hospital patients, the witness determined to have three nerves divided in his own arm. This was done with the most successful results; the question that was put by the operation was answered immediately with a clearness they could not obtain by any other means, and for five years they had been working out the results of that experiment. The problem they wanted to solve was this: There went to the hand nerves which went to the muscles, and nerves which went to the skin. Ordinary accidents divided both. They wanted to know what happened if only the nerves that went to the skin were divided and all the nerves which went to the muscles were left untouched. They desensitized the skin over the whole of the part. They took only the skin nerves and left all the nerves which went to the muscles; the result was that they discovered that under this sensation, which was what they all had when they touched themselves, there lay an entirely unappreciated sensory mechanism, which was responsible for an enormous amount of sensation, but that it ran with muscular nerves, which was an entirely new fact, and a thing which had revolutionized the conception of sensation altogether. In old days they would have been told, if one cut all the sensory nerves going to the skin one desensitized the part. It was nothing of the kind. One must cut the sensory fibres in the muscular nerves before one did that. They could not test the sensation of animals. But the whole point was that running alongside came a series of experiments on the way in which nerves united in animals, which were necessary to show how these reunited nerves conducted. That could be done only on animals. Experiments on animals could not tell them about what a human being felt; for that they required disease. On the other hand, in many of the cases where they had to depend upon human beings they only knew what was the matter with them because they had made that lesion in animals. In reply to Sir William Church, he agreed that *mutatis mutandis* all he had said applied in a very large measure to researches into other organs in man. Experimentation upon animals could not take the place of clinical observation; the one could only be fruitful with the other. He wished to point out the uselessness of experimenting for a practical end. Men had been experimenting for practical ends and observing for practical ends with regard to pain and disease with comparatively little progress. It was only when they determined to see whether they could not apply the theoretical results obtained by Dr. Gaskell to the structure and the functions of the nervous system that they discovered these other laws, which were of daily

practical importance. Practical results were the by-products of a manufacture of which knowledge was the aim. In reply to Sir William Collins, he said he had no doubt that this experiment had revolutionized their conception of sensation. The three nerves he divided were the radial and the two branches of the external cutaneous, one of which ran down the front of the forearm, the other down the back of the forearm. The anatomist had always said that the radial played a considerable part, but when the radial was divided in man they could not find out that anything of the kind happened. Asked as to the part played by the ulnar nerve, the witness said the motor power was accurately known; the sensation was very imperfectly known. Dr. Head proceeded to refer to observations made by Sherrington on animals and by himself upon human beings, where the ulnar nerve had been divided. It was found in those cases that if one gave the anatomist a patient in whom the ulnar nerve had been divided, he could not tell whether it had been divided and partly reunited, or whether it had not been divided, except by looking at the motor supply. If by any chance the motor supply was uninjured, he could not tell in what condition that nerve was; he could not tell whether to cut down and suture that nerve, nor could he tell if one did cut down upon it what one would find. Asked if he would be surprised to hear that a surgeon seeing a case of division of the ulnar nerve at the elbow joint, and finding loss of sensation in the little finger and the adjacent portion of the next finger, had cut down upon the ulnar nerve and resutured it, and found sensation restored, the witness said, Not in the least, because he cut down without knowing, except on the motor side, what he was going to find. Time after time he had known the ulnar nerve cut down upon in ignorance that it had reunited and reunited. Recently a patient of his own, in whom the ulnar nerve was united, was operated upon and the nerve exposed, simply because it was not known whether that nerve was united or not. His experiment referred to deep sensibility. It was found that after the operation a touch with the finger could be appreciated and localized, although the whole of the skin had been rendered insensitive. Secondly, it was found that by pressure pain could be produced with the same amount of pressure as on a normal hand. Asked if the experiment necessitated a revision of their opinions as to the distinction usually drawn between motor and sensory nerves, the witness said, No, between muscular and cutaneous nerves, which was a different matter. Asked if he considered it necessary to make a distinction in speaking of sensation generally between sensation to touch, sensation to pain, and sensibility to temperature, the witness said, Yes, discriminating also heat and cold. Asked whether those forms of sensibility travelled along with the motor nerves or with the cutaneous nerves, he said one form of touch travelled along the cutaneous nerves and one along the deep fibres; one form of pain travelled along the cutaneous nerves and one along the deep fibres. Heat and cold travelled solely along the skin fibres. Localization of a spot touched travelling along the deep fibres did not carry the power of distinguishing two points; sensory impulses travelling from the skin carried the power of discriminating the two points. Those views were new. He supposed the first publication of it was in 1905. Sherrington worked independently, and published his results in the usual way, and it was the witness's knowledge of Sherrington's publications that helped him so profoundly in his research. In reply to other questions, he said that localization of pain would not by itself localize a stone in the bladder. A better instance in some ways was the pain down the inner side of the arm, produced by heart disease, which was a thing not understood at all. Asked if he had worked at the regeneration of nerve he said, Yes. Asked whether he was a centralist or a peripheralist, he replied it would be impossible to say, because they were beginning to see that the problem was not so simple as that. He agreed that both peripheralists and centralists claimed, as the result of experiments on animals, the accuracy of their view because it was like all those things; they had to work on both sides of the question before they ultimately reached the truth. In reply to a question as to a recent paper by Marie in which it was asserted that the third left frontal

convolution did not play any special rôle in the function of language, the witness said it was that very point that was in dispute. It was one of the points that they could not settle by experiment, and which they had to wait for observations. It was one of the earliest localizations and still one of the most disputable. Asked if without his experiment on himself, by experiment on animals alone, could this revolution in our conception of sensation have been attained, Dr. Head said, Not of sensation, but the very fact that Sherrington had told them that there were these afferent fibres made it perfectly certain that there must be a sensory function attached to them. What that sensory function was, was a thing that only a human being could tell them, and that was what they set themselves to show; but the idea would not have come to them had they not had this elaborate work of Sherrington's, which told them that a large proportion of the fibres in the muscular nerves were not motor. In reply to further questions, he said the operation on himself was done under general anaesthesia. There was absolutely no pain above the division during the healing. He went about his work as usual, with his arm in a sling. It healed by first intention. In reply to further questions, he said that in his opinion the knowledge gained by his experiment directly tended to the amelioration of future suffering by more skilful and expert treatment. It had opened up and enabled them to understand things not understood before. It tended to correct errors either in diagnosis or treatment which might have existed in the absence of that knowledge.

(To be continued.)

Medical News.

THE German Society of Tropical Hygiene will hold its second congress this year at Easteride.

At a meeting of the Royal Society of Arts, John Street, Adelphi, London, W.C., at 8 p.m., on Wednesday next, Dr. James Cantlie will read a paper on the part played by vermin in the spread of disease; the chair will be taken by Sir Malcolm Morris, K.C.V.O.

LIEUTENANT-COLONEL J. W. T. GILBERT, V.D., Royal Army Medical Corps (Territorial Force), 3rd Home Counties Brigade, has received the Royal permission to accept the silver medal of the Order of Orange-Nassau, conferred upon him by the Queen of the Netherlands.

MR. F. W. WHITE, 26, Browning Road, Manor Park, Essex, has compiled what he calls a United Daily Calendar, showing the dates of the month on which all the days of the week will fall during 1909. It is for many purposes a very convenient desk companion.

A DISCUSSION on the report of the Royal Commission on the Care and Control of the Feeble-minded will be opened at the meeting of the Child Study Society, at the Parkes Museum, London, on Thursday next, at 8 p.m., by Dr. G. E. Shuttlesworth, Mrs. E. M. Burgwin, and Mrs. Dickinson Berry, M.D.

At the annual meeting of the North of England Obstetrical and Gynaecological Society on January 15th the following gentlemen were elected office-bearers for the year: President, Dr. J. W. Martin (Sheffield); Treasurer, Dr. W. K. Walls (Manchester); General Secretary, Mr. W. H. Phillips (Sheffield).

A DISCUSSION on ulcerative colitis will take place at the meeting of the Medical Section of the Royal Society of Medicine on Tuesday next, at 5.30 p.m. It will be opened by Sir William Allchin, and statistics of cases of ulcerative colitis during the past twenty-five years will be presented from the chief London hospitals.

THE third annual dinner of past and present students of the Royal London Ophthalmic Hospital will be held at the Trocadero Restaurant, Shaftesbury Avenue, London, W., on Wednesday, February 10th, under the presidency of Sir Anderson Critchett, Bart., C.V.O. Further particulars can be obtained from either of the honorary secretaries, Mr. Arnold Lawson, 12, Harley Street, and Mr. J. Herbert Parsons, 27, Wimpole Street, London, W.

THE laboratory of the Chicago Department of Health has recently examined six different systems for ventilating tramway cars, and the Department has given notice that if, after a reasonable lapse of time, arrangements for the installation of one of the approved methods of ventilation are not made, suits will be instituted against each company

for every improperly ventilated car, every day that it is in the service.

IN the Howard Prize Essay, read by Mr. P. E. Braun before the Royal Statistical Society on January 19th, on the "Cost, Conditions, and Results of Hospital Relief in London," the author dealt with the accounts of the London hospitals for 1906. He therefore inevitably included recommendations which are so far ancient history in that they have already been anticipated and dealt with. Nevertheless, the paper was an interesting contribution to consideration of the subject, and some of his conclusions which are of general interest and not open to criticism may be mentioned. He showed that the total ordinary expenditure of 123 hospitals in Greater London reached the enormous sum of nearly one million sterling—in exact figures, £999,982—and that the ratio of management to ordinary expenses was usually lowest in the case of the great general hospitals with medical schools attached. The premier position in this respect was held by St. Bartholomew's. The twelve general hospitals derived 52 per cent. of their united income from invested property. The percentage of persons dealt with by provident and charitable dispensaries and as free patients by private practitioners was quite unknown.

THE good work done by the Hospital for Invalid Gentlemen at 90, Harley Street, has long been recognized and appreciated by the medical profession, and it is to be hoped that the effort now being made to raise money to erect and equip the new building at 19, Lisson Grove, will meet with a full measure of support from the benevolent public. The Duchess of Albany laid the foundation stone of the new building in Lisson Grove on January 18th, in the presence of a distinguished company. The President of the institution, Lord Waldegrave, explained that the objects of the hospital were to afford a home in illness, with medical and surgical treatment, to gentlemen of small means. The last report gives an indication of what is meant by this phrase by furnishing the following list: "The wives, daughters, and relatives of clergymen, naval, military, and professional men, governesses, artists, and others." The patients contributed towards the charges for medical attendance, nursing, and medicine, and the institution thereby afforded an admirable example of how to carry out the true principle of charity of helping those who help themselves. Patients were admitted from all parts of the United Kingdom, from India, from the colonies, and from other countries, and a striking testimony to the valuable work of the hospital was to be found in the praiseworthy efforts made by ex-patients to collect money for the new hospital. A lease of the new site on the west side of Lisson Grove had been secured for 99 years, and it was proposed to erect upon it a compact hospital which would be economical both in building and in management. The new premises would provide 30 beds, and the accommodation would be so arranged that there would be 16 single rooms for patients. The vote of thanks to the Duchess was moved by Mr. W. Bridgeman, M.P., and seconded by Dr. S. Shore Nightingale, a nephew of Miss Florence Nightingale, one of the founders and the first lady superintendent of the hospital.

ASSOCIATION OF MEDICAL LIBRARIES.—At a meeting of those interested in medical libraries, held at Leeds on January 9th, it was decided unanimously to form an association of medical libraries, and a provisional committee was appointed to draw up the constitution and rules. Professor Osler (Oxford) was invited to become the first President, and Professor Walker Hall (Bristol) and Mr. Cuthbert E. A. Clayton (librarian, Manchester Medical Society) were asked to undertake the duties of temporary secretaries. The following are some of the objects of the association:

1. Intercourse of those interested in medical library work and the discussion of matters associated with the fostering and care of libraries.
2. Diffusion of information as to the branches of medical literature specially catered for at different centres, and as to the value of the various books and new periodicals which are issued from time to time.
3. The promotion of measures whereby a larger number of practitioners in each centre may be induced to utilize the library facilities of each district.
4. The consideration of matters connected with the present rapid increase of periodicals, publications of books, etc.
5. The opening up of better chances of advancement for library assistants. By such means there would be an inducement to parents to put their sons to such an occupation, and the librarians would be able to have better material for training.
6. The exchange of duplicate books and periodicals.

When the association is in working order, it is hoped that a certain number of the libraries interested will join together to form a circle for the loan of their research and other literature.

British Medical Journal.

SATURDAY, JANUARY 23RD, 1909.

THE FURTHERANCE OF RESEARCH.

It is with particular pleasure that we welcome the announcement that an anonymous benefactor has given £20,000 to the Medical School of the London Hospital, with the express stipulation that the interest accruing therefrom shall be applied solely in furtherance of medical research. The fund has been placed in the hands of the trustees of the school, who will pay the proceeds yearly to three administrators selected by the donor. These are the Hon. Sydney Holland, the Chairman, and two members of the acting staff of the hospital. Under the terms of the gift its benefits are not to be confined to students educated at the London Hospital, but will be open to qualified medical men from any part of the British Empire who are willing to prosecute original investigations in the field of medical science within the walls of the London Hospital or College.

Benefactions to hospitals are by no means rare in this philanthropic country: the peculiar feature of this gift is that it is to be devoted not in aid of the ordinary charitable work of the hospital, but for the promotion of medical knowledge by research. Although antivivisectionists are always trying to make the public believe that scientific investigation is well paid and is undertaken with the object of gaining money, it is unfortunately the fact that one of the obstacles in the way of progress is that so few men can afford to give time to work that, however profitable to mankind, too often does not supply them even with the plainest living wherewith to support the high thinking necessary for research. Hence many young men consumed with what Huxley called the divine thirst for knowledge, and gifted with the ability to wrest secrets from Nature, have to give up to practice what was meant for mankind. It is a discreditable sign of the spirit which animates a section of the public that, whereas large sums are got from sentimental persons by societies which have never succeeded in saving a single guinea-pig from a needle prick or a superfluous dog from a painless death in the laboratory, appeals for money for use in the acquisition of knowledge that would lead to the alleviation of pain in thousands of human sufferers, and probably to the extirpation of some of the diseases that afflict our race, meet with a very inadequate response.

Splendid gifts have, of course, been made occasionally by enlightened persons. The Lister Institute is a standing proof of the enthusiasm of humanity that animates Lord Iveagh. The Imperial Cancer Research Fund is another evidence that there are among us men who know how to make their wealth useful to their fellow creatures, but we believe the work of that noble monument of philanthropy is still crippled by want of money. The Cancer Investigation Fund of the Middlesex Hospital, which was established for the purpose of "curing persons afflicted

"with cancer and of investigating and promoting our "general knowledge of treating that dreadful disorder," is another institution of which we are justly proud, and endowments for research in physiology and pathology are given by various bodies. Among these may be mentioned the Sharpey Scholarship at University College, London; the Gillson Research Scholarship of the Apothecaries' Society; and the Lectureship on Experimental Pathology founded by Mr. Robert Gordon at Guy's Hospital. But there is not one of these that would tempt any one not devoted to the work for its own sake. From a financial point of view the income derived even from the humblest practice is larger than that offered by any of them.

Men who wish to give themselves to original investigation are obliged for the most part to content themselves with posts as assistants in medical schools where they have to give a large part of their time to the arduous work of teaching in exchange for the opportunities of research. As an example we may cite a case within our own personal knowledge in which one of the first of living histologists served for eleven years at a great university in a subordinate position in which his salary never exceeded £250. Even professors are often paid at a rate that would be scorned by many a city clerk.

If in Germany the vineyard of research attracts more labourers than it does here, the reason is that the German Government is wise enough to see the value of such work and to grant liberal subventions for its support. In America there has in recent years been a kind of rivalry among two or three millionaires in the endowment of research; but it is questionable whether the vast sums that they have given are put to the best use. In some cases the money is given for the foundation of palatial laboratories while no provision is made for their maintenance. Hence the work done has not always been in proportion to the apparent magnificence of the endowments. In this country no Government would give any but the scantiest subsidy for scientific work, because such expenditure of money would bring no votes, and would be the object of much criticism. While due acknowledgement must be made of the liberality of a few far-seeing men, it is not too much to say that the funds for research work have to a large extent been supplied by the medical profession itself. Taking the Middlesex Cancer Investigation Fund as an instance, while the founder gave between £3,000 and £4,000, and Lady Stafford £5,000, over £35,000 was contributed by a physician, Sir Joseph de Courcy Laffan. The British Medical Association has during the last twenty-five years given more than £20,000 in scientific grants and research scholarships. It has also given nearly £2,000 to various societies in aid of scientific research. In addition to these sums the Association has spent between £3,000 and £4,000 on collective investigations concerning a number of common diseases. It has spent more than £1,000 in researches on anaesthetics, an almost equal amount on investigations as to new drugs; between £600 and £700 in the collection of data relative to feeble-minded children, and further sums in inquiries as to the eyesight of railway servants and sailors, and the decay of teeth. Moreover, the Association has encouraged research work in ophthalmology and public medicine by the bestowal of prizes. Of the many benefactions for the encouragement of research made by individual members of the profession we need not speak.

In matters of benevolence, as in other things, deep often answers unto deep. It may therefore be hoped that the example of the anonymous benefactor whose gift to the London Hospital Medical School will so largely increase its power for good, may be imitated by other lovers of their kind. Next to the actual relief of suffering by known methods—most of which now in use, it may be said parenthetically, are the fruits of research—there is no way in which money can be spent with greater certainty of promoting the greatest good of the greatest number than the provision of means for the discovery of new truths from which may spring more effective methods of stamping out disease and promoting the health and thereby the happiness of the human race. But it must be remembered that the work, if it is to be profitable to science and to mankind, must be done with the sole object of getting at truth without direct thought about its practical application. It is not always the man who finds or makes the materials who builds the house.

SIDELIGHTS ON WORKMEN'S COMPENSATION.

IN order to form an accurate idea of the practical working of an Act of Parliament one must do more than read the law reports of cases published in the newspapers. In the matter of workmen's compensation, for instance, there is much which can only be learnt from practical experience—experience which is chiefly gained by members of the legal and medical professions. At a recent meeting of the Law Society, Sir John Gray Hill, an ex-President, took occasion to state his views on the practical working of the Acts. The report of what he said is not pleasant reading for those who have sounded the praises of this famous measure. We are not concerned to deal with all the legal difficulties which he exposed, but he drew attention to some matters of medical interest which it may be worth while to record.

He first endeavoured to penetrate the nebula which has surrounded the definition of the word "accident" in relation to infectious disease. As the law now stands, it is almost impossible to say with certainty whether a person suffering from any particular complaint is the victim of an accident within the meaning of the Act. On the one hand, anthrax acquired by a woolsorter and heat-stroke sustained by a stoker have been held to be accidents. On the other hand, poisoning by red lead and subcutaneous cellulitis over the patella (miners' bent knee) have been held not to be accidents.

Confusion has also arisen in relation to the question whether a workman can be required to submit to an operation calculated to increase his working capacity. In this matter the English and Scottish courts have taken opposite views; the English Court of Appeal laying it down that a man may not be compelled to undergo an operation by a promise of increased compensation. Dealing lightly with these two matters, Sir John Gray Hill said: "The bacillus of Naaman the Syrian probably arose out of and in the course of his employment, and was, I presume, on the authority of the anthrax case, an accident. If he had come under the Act, and had persisted in his refusal to dip seven times in Jordan, the Court of Appeal would probably, on the authority of *Rothwell v. Davies*, have refused to stop his allowance from his employer the King of Syria."

Passing, however, to an even more serious question—namely, the moral effect of the Workmen's Com-

pensation Act—Sir John brought forward much information he had collected of a disquieting character. He has taken counsel with several members of the medical profession, who had, he said, opened his eyes to some of the serious results of an Act which should do nothing but good.

He quoted an extract from the address at the Sheffield meeting of the British Medical Association, in which Mr. Pye-Smith said: "It is sad to find by painful experience to what an extent unfair advantage is taken of this Act by some of those for whose benefit the laws were framed. Instead of honestly trying to get back to work as soon as possible, thus proving their manly independence and retaining their self-respect, the injured workmen, in too many instances, try to persuade themselves and their medical examiners that they are incapacitated for work long after their condition justifies such a contention. The hope of obtaining a lump sum as compensation no doubt acts in some cases as a strong motive to profess that no improvement is taking place in their condition."

A very similar tale was told by the senior physician to a Liverpool hospital, who said: "From our experience, the Act has in general exercised a decidedly demoralizing effect on workmen, especially on those who are, as a rule, disinclined to steady labour. We are pestered with friends making the most ridiculous claims for compensation where no grounds exist, and even in cases of heart disease they assert that 'some trifling accident accelerated death.'" The same physician told the following story. A workman who had received an injury to his hand was given £75 in lieu of weekly payments. Before long he came to the hospital suffering from delirium tremens. He told the doctor that he had spent £60 on drink, and £15 on his friends. "He seemed," added the doctor, "to take a pride in telling the story."

Sir John also mentioned a case in which a firm on medical advice paid £100 in compensation. Within a few months the wife of the injured man summoned him for a separation order on the ground of persistent cruelty, alleging that since the payment he had done very little work, and he then admitted he had only £3 left out of the £100. The average workman is neither a malingering nor a drunkard, and it is difficult to see why the Act cannot be amended so as to give less opportunity to those who have these tendencies.

As one of the means for preventing malingering, Sir John Gray Hill suggests that an amending Act should provide for the appointment of a medical assessor to sit with the county court judge on the demand of either party, making provision for a sufficient remuneration to him." As a footnote he adds: "This would also afford a good check upon the unreasonably divergent testimony of medical witnesses."

There is a blacker side of the working of the Compensation Act that does not seem to have been touched upon by Sir John Gray Hill. In France, as we gather from some of the medical journals, there are doctors so lost to all sense of professional honour as to make a practice of giving false certificates which are used by workmen to extort compensation. It would be difficult to find words strong enough adequately to condemn such an offence, which is calculated to reflect discredit on the whole profession. We observe that the Royal College of Surgeons in Ireland has a by-law providing that "any Fellow who shall be convicted before the Council of having made a false or corrupt report, or gives a false certificate

"to any magistrate, insurance company, public board, or other body or individual, respecting the state of health of any person, shall be expelled;" and that if a Licentiate be so convicted, "his letters testimonial shall be withdrawn." We have no doubt that every other college in the United Kingdom would likewise enforce the most stringent disciplinary measures, and that the General Medical Council would be equally ready to take effective action. Probably the suggestion that a medical assessor should always be at the side of the county court judge when claims for compensation are dealt with, which we are glad to see has the approval of Sir John Gray Hill, would go a very long way towards deterring dishonest workmen or their advisers from attempting to institute proceedings founded on fraud. That there are undue temptations to workmen of easy conscience not only to claim compensation for injuries which are not permanent, but also to malingering in order to get weekly compensation from the employer, and sick pay from the club, is well known to all medical men, and was clearly stated by Sir Thomas Oliver in his address before the Life Assurance Medical Officers' Association, published in our columns on November 14th, 1908.

THE FUTURE TREATMENT OF THE INSANE.

At a meeting of the Westminster Division of the Metropolitan Counties Branch, a report of which is published in the SUPPLEMENT to this week's issue, an interesting discussion took place on the future treatment of insanity. It is matter for regret that Dr. Savage, who was to have opened the discussion, was unable to be present. Dr. Ewart, the chairman, said that the urgent question of the day was that of the environment suitable for different stages and varieties of insanity, and that the view, so often advocated in this JOURNAL, that special hospitals were needed was gaining ground. That this is the case was abundantly shown in the course of the discussion. Dr. Mott put the case for hospitals where acute cases could be treated without going through asylums and without receiving the brand of certification. Referring to Dr. Maudsley's offer of £30,000 to the London County Council towards the foundation of a hospital for mental disease, to which reference was made in the JOURNAL of December 19th, 1908, p. 1828, and on several previous occasions, Dr. Mott said that Dr. Maudsley was anxious to see the institution in being, but as yet nothing had been done owing to the alleged difficulty of finding a suitable site. In connexion with this subject he related an incident which points a moral the London County Council would do well to take to heart. Soon after Dr. Maudsley's munificent offer was announced, a similar scheme was mooted at Baltimore, and the architect and the future director of the hospital were sent to Europe to learn what was being done. On hearing how matters stood, the architect said to Dr. Mott that probably the Baltimore hospital would be completed while the London Aediles were still thinking how they were to begin. Dr. Coupland said that the proposals to deal with incipient insanity without legal certification, to encourage hospital treatment and the formation of farm colonies, indicated advances that might result in the gradual elimination of such cases from large asylums, which from their very character could not be so helpful towards restoring a patient to sanity as more limited and home-like surroundings. Many asylums, he added, were now provided with detached buildings for the hospital treatment of acute cases, but, generally speaking, it would almost seem as if England, the pioneer in the

more enlightened and humane treatment of insanity, had fallen behind other nations in certain respects. He looked forward to her regaining her position through the influence on public opinion effected by the labours of the Royal Commission and the enlarged opportunities for scientific study of the subject in accordance with the aims of Dr. Maudsley and Dr. Mott. The debate was brought to a close by the unanimous adoption of a resolution that the London County Council should be urged to take immediate steps to establish the hospital suggested by Dr. Maudsley. We hope this expression of professional opinion will stir the Council into activity. While fully recognizing that there may be some difficulty in finding a suitable site, we cannot help thinking that there must be a certain lack of earnestness in regard to the scheme among those whose business it is to carry it into effect. Enthusiasm is a mighty driving power, and we should like to see some manifestation of that force on the part of the London County Council in the direction indicated. It is possible that there may be obstacles, subtle but none the less effective, in other quarters which may be held to justify delay. Public bodies, even more than individuals, are always ready to find specious excuses for inaction when they are not particularly eager to act. The lazy man can always find a lion in his path, if he wishes to do so. We feel bound to say that a most serious responsibility will lie upon the London County Council if it fails to act on the strongly expressed recommendations of its own Asylums Committee.

ALCOHOLISM AND FEEBLE-MINDEDNESS.

At a recent meeting of the Society for the Study of Inebriety a thoughtful paper was read on this subject by Dr. W. A. Potts of Birmingham, lately one of the medical investigators to the Royal Commission on the Care and Control of the Feeble-minded. Commencing with an avowal of his conviction, in accord with the views expressed by Drs. Bevan-Lewis and Shuttleworth, that the origin of mental defect is nearly always complex, he pointed out the difficulty of picking out a single factor and attempting to ascertain how far its influence extended. He adduced instances from the family histories of special-school children showing how frequently both alcoholism and phthisis coexisted in the parentage, and in some cases also a neuropathic heredity. Etiological truth lay somewhere between the extreme views held on the one hand that alcohol had little or nothing to do with the feeble-minded, and on the other that it was the most important cause of all. After a few words on the general action of alcohol, which (as Dr. Mott had pointed out) he considered paved the way for the far-reaching effects of other injurious agencies, Dr. Potts proceeded to consider the influence of heredity. He argued that, admitting to the full Weismann's dictum that acquired characteristics cannot be transmitted, there was still ample scope for the production of injurious results in the offspring if the parents are exposed to toxins of various kinds. Alcohol circulating in the maternal blood might directly poison the germ cell and interfere with its due development. The embryo, moreover, might be adversely affected by similar conditions, and as a result there might be an interference with formative processes, leading to physical deformities or nervous abnormalities. After quoting Leppmann's statistics as to the infantile mortality among drunkards' children in Paris—42 per cent. dying during their first year—Dr. Potts maintained that impaired vitality and nervous instability might result from parental alcoholism. Amentia of greater or less degree has been traced by Dr. MacNicholl, of New

York, to parental alcoholism, and he found that whilst amongst school children free from hereditary alcoholic taint 96 per cent. were proficient, 4 per cent. dullards, and 18 per cent. sufferers from neurosis or organic disease; the corresponding figures for those with hereditary alcoholic taint were 23, 77, and 76 respectively. Reviewing the diverse opinions expressed by witnesses before the Royal Commission (some of whom, notably Miss Dendy and the late Dr. Ashby, assigned little importance to parental alcoholism as a causative factor), he cited the result of Dr. Tredgold's exhaustive investigation of 150 cases of amentia, which was that, while a neuropathic inheritance seemed to be the chief cause, alcoholism *with* such inheritance accounted for 38.5 per cent. of his cases, and, *without* such inheritance, for 8 per cent., making a grand total of 46.5. Dr. Potts and Mrs. Hume Pinsent had found, on examining 250 mentally defective and 100 ordinary children in the Birmingham schools, that alcoholic heredity in a direct line obtained in 41.6 per cent. of the former and in only 22 per cent. of the latter. In conclusion, Dr. Potts recorded his opinion that "the evidence is not clear that alcoholism, by itself, in the father will produce amentia, but that in combination with other bad factors it is a most unfavourable element; while maternal drinking, and drinking continued through more than one generation, are potent influences in mental degeneracy."

HOSPITAL ABUSE IN NEW ZEALAND.

A LETTER which we have received from a New Zealand correspondent appears to prove that hospital abuse is still in its infancy in this country, and that exploiters of the medical profession at home have a great deal to learn from our democratic colony. According to our correspondent, every town and every rural district in New Zealand has its hospital or hospitals. These institutions are supported by the public, who subscribe 26s. a year, and by a Government grant equal to the amount of the public subscriptions. These hospitals are staffed by salaried medical officers whose average remuneration, we are told, is about £200 a year for a hospital of 18 beds, with an unfurnished residence. But the doctor's duties are not confined to attendance on the occupants of these 18 beds. Every annual subscriber of 26s. a year, within a radius of seven miles, is entitled to the free service of the medical officer for himself, his wife, and his family; if he goes into the hospital he has to pay a further sum of 5s. a day for maintenance. Naturally the majority prefer that the doctor should do the travelling and save them 35s. a week. Under these circumstances the statement that "private practice is allowed," as an additional inducement to men to take up these positions, appears to be conceived in a vein of dubious humour. On the whole it would seem that our correspondent is justified in saying that "the hospital is a Government subsidized competitor against all medical men, and particularly against its own appointed medical men." He encloses two cuttings from the *New Zealand Herald* in confirmation of his statements. One of these describes a conference of delegates from the New Plymouth, Hawera, and Stratford Hospital Boards. In view of the fact that members of the medical staffs, in addressing the conference, had made frequent use of the words "charity" and "charitable aid" in connexion with the hospitals, the following resolution was adopted: "That, having in view the fact that every member of the community contributes directly or indirectly, or both, to the erection and maintenance of public hospitals, this conference affirms the principle that any person is entitled to

"claim admission to such hospitals for treatment as a matter of right, and not of privilege or charity." This is at least clear and straightforward, and no doubt, if the Governor of New Zealand were to contribute to a soup kitchen, the same conference would regard him and his family as eligible recipients of tickets for soup. In a subsequent issue the same journal publishes an interview with Mr. L. J. Bagnall, "one of the most prominent members of the Auckland Hospital and Charitable Aid Board." It is a little surprising that the word "charitable" is still allowed to blot the title of this board. However, Mr. Bagnall admits that "in some towns the misuse of the hospitals has become so serious that doctors are unable to obtain a living." This is apparently regarded as perhaps an unfortunate fact, but necessary for the good of the Commonwealth. In the New Zealand ethical system it would be a far greater injustice that the well-to-do should pay for medical attendance. Mr. Bagnall adds that if the doctors' contention that they should be paid for attendance by those who can afford to pay were admitted, "we should find ourselves in the position of having to pay all the doctors who give their services at present for nothing, which would mean, in the case of the Auckland Hospital, an extra cost of at least £1,500 a year." This remark closed the interview. Evidently the prospect of the payment of this sum to the men who had earned it was too much for the tender consciences of the New Zealand journalist and the dispenser of "charitable aid."

ARTIFICIAL LANGUAGES.

THIS is an age of many inventions. Among these not the least remarkable is the crop of artificial languages which has sprung up within the last quarter of a century. Volapuk, the "blue language" and others, have vanished, while Professor Henderson's "Lingua," Dr. Molenaar's "Panroman" and Karl Lentze's "Interpretor" can scarcely be said to have breathed. Esperanto has shown more vitality. How long will this last? It is not a code of rules artificially framed that makes living speech; the grammar merely represents the results of an analysis of spoken language. If Esperanto is to be a living tongue it must inevitably suffer the changes which natural languages undergo. A conventional language is stricken from the first with barrenness if it is not transmuted into a living tongue. In the case of an artificial language there is an additional modifying factor of incalculable power to be reckoned with. This is nationality. A language must be adapted to racial and social characteristics. It is a natural growth subject to modifications, as the people whose means of expressing themselves it is adapted themselves to changes of environment, mode of life, intellectual outlook, and moral conventions. Hence if Esperanto lives long enough, its grammar, even among those who strive hard to preserve its pristine "purity," must become more and more complex as exceptions forced upon it by the development of civilization and the exigencies of new conditions increase and multiply. An artificial tongue bound within the rigid structure of its original framework can never adapt itself to the varying phases of human evolution, or even to the expression of national sentiment in its slow but steady changes. Hence it can never be the language of art or literature, or even science, but must at best be a *lingua franca* adopted by certain persons in each country for practical convenience. We agree with Dr. Champeaux, who, discussing the subject in the *Revue Philosophique*, says, as we have often said, that it would be better to return to Latin; or if that is a counsel of perfection, the *Volkslatein* or popular Latin suggested by Hermann

Diehls or Dr. Ch. Colombo's "Latin Commercial" might with advantage be adopted. That would at any rate help us to keep a key that opens the door to the masterpieces of literature. Notwithstanding all that is said about the spread of Esperanto, the problem of an international scientific language is so far from being solved, that quite recently Dr. Paul Sollier, after predicting that Esperanto was about to be dethroned by another artificial tongue, "Ido," went on to propose that French should be definitively chosen as the language of science, while English should be the language of commerce. The inevitable congress on the subject was to be held at Luxembourg. What the outcome of the congress was we are unable to say. Since then we have received a draft of another new tongue invented by Elias Molce, Ph.D. It is to be called "Tutonish," and is described as "an International Union Language, under a Liberal 'Anglo-Saxon Leadership.'" This is not so ambitious as Esperanto, as it is merely "simplified English." But whether the international conference of English, American, German, Scandinavian, and Dutch "legally-appointed linguists" would accept it is somewhat doubtful. The fact that so many rivals are in the field is sufficient to prove that Esperanto does not altogether justify the claims made on its behalf by enthusiasts, some of whom, like certain leaders of the Gaelic restoration in Ireland, would find a difficulty in carrying on a conversation in the jargon in which they profess to see the universal language of the future.

THE DEFINITION OF HYSTERIA.

THERE are probably few who feel satisfied with the accounts of hysteria to be found in systematic works. It is usual to avoid anything like a definition of the disorder, but to describe a series of symptoms which have been from time to time called "hysterical." Some of these are unknown or almost unknown in this country, and our accounts of them are chiefly taken from French writers; it is therefore extremely interesting to read a criticism of the accepted French views by one of the most brilliant French neurologists, Dr. Babinski, the well-known physician to La Pitié Hospital in Paris. An old Chef de Clinique of Charcot at the Salpêtrière he was originally deeply imbued with the teachings of his master, but subsequent experience has led him to modify his opinions, and so long ago as 1901 he maintained in a communication to the Société de Neurologie that a great deal had been included under the name of hysteria which does not properly belong to it. In his present essay¹ he affirms that much of what is called hysteria is organic disease, or mere imposture. He proposes as a test for what is hysterical that it should be curable by suggestion, or conversely only those phenomena should be called hysterical which can be produced by suggestion, and for this group he proposes a new name—"pithiatic," or curable by persuasion. He declares that a great number of the phenomena described by the Salpêtrière School have disappeared from the Paris hospitals since less attention has been paid to them. It has always seemed to us that either hysteria was different in France from what it is in England, or that many conditions were included by French writers which had really nothing to do with this neurosis, and it is therefore not altogether surprising that there should be this indication of a reaction against the teachings of thirty years ago.

MOTOR AMBULANCES.

WHEN motor ambulances for use in connexion with street accidents were first introduced in America some years ago they were a decided failure. Since then great advances have been made both in ordinary

automobile manufacture and in the adaptation of electrical and other motor engines to vehicles for use as street accident ambulances. At each of the exhibitions at Olympia within the last few years admirable ambulances of a self-propelled type have been on view, and those which came into use a year or more ago in the City of London have proved, it would seem, an entire success. It is clear, therefore, that motor ambulances are destined to take the place, sooner or later, of horse-driven vehicles of the same purpose in all places where work of this sort is thoroughly organized and on a large scale. For this reason a suggestion put forward a short time ago by a contemporary named *Motor Traction* is timely, and well worthy of consideration by the authorities. It was to the effect that bodies such as the Metropolitan Asylums Board, the London County Council, the St. John Ambulance Association, the Metropolitan Street Ambulance Association, the principal London hospitals, and bodies of like type in the provinces, should put their heads together and decide upon the ideal length and breadth and other measurements of a hand stretcher. If this were done the builders of motor bodies would make sure that all ambulances turned out by them were so constructed as to carry a greater or less number of stretchers of the indicated size. There is no doubt that some such step might well be taken; for while it is not desirable to tie the hands of those who manufacture stretchers in point of material, weight, and general construction, there is at present an entirely superfluous degree of variety in point of size. The dimensions, in short, of stretchers might well be standardized, and standardization of the carrying capacity of ambulances would follow. This would be an advantage, because in that case it would often happen that a patient was ready waiting on a stretcher of suitable size for insertion into an ambulance when the latter arrived, and the rapid transport of the injured person to his home or a hospital would be facilitated. A by-result might also be a reduction in the cost both of ambulances and stretchers, for standardization of size has been found to have this effect in connexion with many important industries, such as cycle manufacture, bridge building, and the like.

FALSE CERTIFICATES OF STILLBIRTH.

AT page 254 of this issue will be found a record of the concluding stage of a case in which the burial of a child was secured by two women who falsely declared that they had been present at its birth, and that it was stillborn. The body was exhumed, and examination showed that it was a healthy full-term child, that its lungs were partly inflated, and that probably it had died merely from neglect immediately after birth. This is an addition to the many cases from time to time recorded in these columns, which abundantly prove the need for alteration in the law regarding certification of death and regarding the interment of children allegedly stillborn. Before 1874 stillborn children, if not buried in the back garden, were freely received by the cemetery authorities; since that date they have been bound to demand either a medical certificate of stillbirth, an order from the coroner, or a declaration of stillbirth from some person who, if the child had been born alive, would have been obliged to register its birth. In addition, one of the sections of the Notification Act of 1907 entails notification to the medical officer of health of the birth of a child which has reached a gestation period of seven months, even if stillborn; and the rules of the Midwives Board oblige midwives to notify to their supervising authority the birth of stillborn children. These latter regulations, however, do not

¹ *La Semaine Médicale*, 1909, p. 3.

materially improve matters, neither of the authorities mentioned being directly concerned in the prevention of improper burials. Things, therefore, remain very much as they were thirty-four years ago; as they were at the date when a Select Committee of the House of Commons, under the chairmanship of Sir Walter Foster, drew up an exhaustive and excellent report on the general subject of death certification; and as they were when, nine years ago, we devoted a series of editorial articles to this subject giving reasons for the regret expressed that no effect had been given to the recommendations of the Select Committee. Since then the only progress to be recorded is that last session two bills dealing with certification of deaths got as far as being introduced in the House of Commons. At the present moment we only desire to refer to the special point of stillbirths, and to point out that in the present state of the law nothing stands between the quiet putting away of a child which is only "stillborn" because it has not been allowed to live but the caution of cemetery authorities in accepting declarations from persons who are neither medical men nor coroners. Things, indeed, may be considered even in a worse state than before, for it is natural that—as in the case which is the basis of this note—cemetery authorities should freely accept declarations from midwives, since they now have a kind of official character. There are, in short, the strongest grounds for holding that every case of reputed stillbirth not certified by a medical man should be the subject of an immediate official inquiry. This is clear when it is remembered that a child which has got so far towards independent existence as to have its head or even its thorax free and to be able to emit cries can, however great its inherent vitality, be intentionally destroyed with the greatest ease, and yet no charge of murder would lie against the person ending its existence, however base the motive, however open the means. Nor, indeed, would the perpetration of such a moral, though not legal, crime, be in the majority of cases easy to prove by a medical man not actually present at the birth, even if the child from a medical point of view was in nowise stillborn. What constitutes stillbirth is a subject on which textbooks on obstetrics are for the most part singularly silent, and it is possible that there is some variation of practice with regard to the certification of children who scarcely survive delivery, or die during its course. This, however, does not affect the point to which it is desired to draw attention, namely, that at the present moment it is perfectly easy not only to kill intentionally and with the basest motives a perfectly healthy child during or immediately after birth, without running the risk of a charge of murder, but to secure its interment without a medical certificate and without inquiry.

HISTOPATHOLOGY OF THE VERMIFORM APPENDIX.

ALL who have stayed in Copenhagen know the name of Carlsberg and of his munificent bequests to art and science. By the aid of one of the Carlsberg Funds there has just been issued a valuable monograph on the pathology of the vermiform appendix by C. U. Maaløe.¹ This consists of some 266 pages of Danish text, a short summary of the main points in English by H. M. Kyle, D.Sc., and 56 excellent photomicrographs. Some of the photographs are stereoscopic, and all are exquisitely reproduced. The book and plates have been sent to the English-speaking pathological institutes, where they will be found of great use for purposes of demonstration. On behalf

of English medicine, we take the opportunity of thanking the Trustees of the Carlsberg Fund for defraying the expenses of this issue. After describing some work on the blood vessels and musculature of the organ, Maaløe refers to the appearances of the follicles as shown in photographs taken from a series of preparations of the caecum and vermiform appendix after treatment with weak acetic acid and glycerine. The follicles stand out as opaque areas. From a consideration of appendices removed from persons whose ages varied from 4 months to 83 years, Maaløe considers that the follicles increase in size and number up to 18 years. After this period there is a gradual decrease, which commences at the apex and continues proximally to the caecum. While this atrophy increases with age, it varies individually, so that there may be extremely different pictures at the same age. It is only the course of the atrophy which seems to be constant. Maaløe injected the lymphatics of the submucosa, and found a small-meshed network at the base of the Lieberkühn glands. The follicles are surrounded, but not pierced, by lymphatics. He does not accept the view that the appendix is an organ which is in process of disappearance. He looks upon it rather as a specialized lymph organ, whose activity increases and decreases according to the calls made upon it, and is related to that part of the intestinal digestion dependent upon bacterial action (decomposition of cellulose). Discussing obliterations, occlusions, and strictures of the appendix, Maaløe expresses the opinion that the view of Ribbert, that the obliterating process begins at the end of the organ and continues regularly from there in a proximal direction, at the same time pushing the mucous membrane in front of it, does not fully state the case, since he met with as many cases of localized inflammatory obliterations as otherwise. There are two factors, therefore, which come into play—inflammation as an occasional factor, and involution as the disposing factor. After detailing the histological appearances of cases of diverticula of the vermiform appendix, Maaløe concludes that these diverticula are in the great majority of cases to be considered as pulsation diverticula, which in the form of mucous membrane herniae have passed out through lymphatic or vascular spaces or chance pathological defects. These diverticula contain mucus, epithelial cells, and leucocytes in uncomplicated cases, and often become the seat of inflammatory reaction and subsequent perforation. Even if the latter does not occur, recurrent attacks and extensive adhesions are common results of this condition.

ADULT MALE WITH UTERUS BICORNIS.

A VERY marked instance of pseudo-hermaphroditismus masculinus internus in a married man 59 years old has recently been reported by Arnolds of Dusseldorf. The patient was under treatment for diabetes, but was a robust man with a good beard, hairy chest, and fully-developed penis and scrotum, though he was a cryptorchid at birth. When about 12 years of age it appeared that he felt something like a testicle coming down, and that he pushed it back again, as it was painful. A few years later a testicle undoubtedly appeared in the left inguinal canal. He had been married since the age of 40 to a widow who had borne children to her first husband, but this second union proved barren. The patient, however, was, it appears, quite potent until his virility had been lowered by diabetes. The left testicle began to swell, then it grew very painful, and the bowel in the painful

¹ *Histopatologiske Studier over Processus Vermiformis*. By C. U. Maaløe, M.D. Published by the aid of the Carlsberg Fund. 1908. Copenhagen: Lund.

¹ *Pseudohermaphroditismus masculinus internus*. Report of meeting of Niederheinisch-westfälische Gesellschaft. I. Gynäk. Monatschr. f. Gyn. u. Gyn., October, 1908, p. 463.

left inguinal canal was strangulated three times, but on each occasion it was reduced by taxis. The patient could not tolerate a truss. Arnolds examined the parts, and found that the right testis was wanting. What was taken for the left was apparently converted into a tumour as big as a man's fist, but some cord-like structures and other unfamiliar movable tender bodies were defined on palpation, malignant disease was diagnosed, and so Arnolds operated. He removed the tumour entire, without dissecting it out of its envelopes. He tied off very large blood vessels, until he came to a kind of pedicle—a tough cord which ran from the abdominal cavity into the inguinal canal. It was as thick as the man's little finger, and when divided Arnolds could see that its lumen was wide, and on further inspection detected a narrower lumen on each side of the wider canal. The inguinal canal was closed by a radical operation. The tumour was dissected afterwards. Instead of being a cancerous testicle it was a perfectly well-developed uterus bicornis unicollis, with two full-sized Fallopian tubes and two genital glands with relations precisely like those of the female ovaries. The wide lumen was the cervical canal, the symmetrical smaller lumina were relics of the Wolffian ducts. The genital glands were examined microscopically, and proved to be testicles, each with an epididymis but neither with a vas deferens. The cervix had formed the long cord or pedicle of the "tumour" (that is to say, the two cornua and appendages), proceeding, it appears, from the back of the prostate, so that it probably opened into the caput gallinaginis. The patient recovered, but returned to Arnolds two months later on account of severe local pain and constipation. A big tuberosus mass could be defined in the upper part of the abdomen, lying across the lumbar spine, immovable and apparently retroperitoneal. The presence of diabetes made Arnolds suspect that the tumour was pancreatic, but no fat passed in the stools. Possibly, he adds, it may have developed in relics of the genital tract, near the kidneys. This case is one of the most distinct instances of the presence of a uterus in an undoubted male ever recorded.

A CONDEMNATION OF ANTIVIVISECTIONISM.

AT the sixtieth annual convention of the American Association for the Advancement of Science, held at Johns Hopkins University during the week commencing December 28th, 1908, the governing council adopted the following resolution: "From time to time attempts, fostered largely by erroneous statements and accusations and false sentiment and prejudice, are made in some parts of the country to enact specific legislation prescribing the conditions under which experiments on animals may or may not be performed. Be it resolved by the Association for the Advancement of Science that animal experimentation has been of incalculable benefit to medical science and art, the progress of which is absolutely dependent on experimental methods, as are all the physical and natural sciences. That no abuse of the practice of animal experimentation in the country has been shown to exist to warrant specific legislation relating to the general subject of prevention of cruelty to animals. That the unrestricted performance by proper persons of scientific experiments on living animals is essential to the maintenance and progress of medicine and biology."

THE NATIONAL LIBRARY OF WALES.

SIR JOHN WILLIAMS, who has since his retirement from practice added very largely to his library of Welsh literature, has now handed over the whole collection numbering some 20,000 volumes to the

governing body of the National Library of Wales, which was established by Royal Charter in March, 1907. The old Assembly Rooms in Aberystwith, until recently used as scientific laboratories by the University College, have been remodelled and fitted with steel book stacks to hold 80,000 volumes, while a fire-proof strong room for storage of manuscripts and rare books has been provided. Sir John Williams's gift includes the Shirburn collection, formed between 1690 and 1740 by the Rev. Samuel Williams and his son, the Rev. Moses Williams, F.R.S., which had been in the possession of the Earls of Macclesfield at Shirburn Castle since 1749; it includes manuscripts in Welsh and Cornish, and by subsequent additions Sir John Williams has raised the total number of manuscripts to about 500. Among printed books the library is particularly rich in Bibles, prayer-books and hymn-books; it contains every Welsh Bible printed before 1800, and two of the first Bibles printed in 1588. In addition to the purely literature there are many books in Gaelic, Irish, Cornish, and Breton.

THE ASSOCIATION'S HOUSE.

THE new house of the British Medical Association at 429, Strand, has been in use for several months for the central work of the Association, and the suitability and general amenity of the building is gratefully acknowledged by all who have occasion to use it for long or short periods. All the central committees have been meeting in the building and the Central Council will use the new council room for the first time on Wednesday next. This is a handsome apartment with a dome-shaped roof; it is lighted by day from above, and at night by side-lights; it is panelled in light oak, and upholstered in dark green leather. The library, which is a large room on the first floor, with a gallery in the mezzanine floor, is panelled in mahogany, and lighted by lofty windows. The workmen have now nearly completed the internal fittings of the library, but the task of arranging the books on the shelves and revising the card-catalogue will be tedious. Meanwhile, as members are aware, the common room on the third floor is arranged as a reading room, where current periodicals can be consulted.

MEDICAL OFFICERS OF HEALTH AND PRIVATE PRACTICE.

THE Public Health Committee of the British Medical Association has presented to the Divisions a report, reproduced in the SUPPLEMENT this week, on the desirability of health officers being required to give their whole time to the work. This action has been taken in accordance with the instructions of the Annual Representative Meeting at Sheffield; but, as the committee point out, the question is most conveniently considered in the form: Should medical officers of health be debarred from engaging in private practice? The memorandum embodied in the report sets out the reasons in favour of whole-time appointments and those to the contrary with impartiality, refraining from any expression of opinion.

A MEETING in support of the British Medical Benevolent Fund will be held at the Royal College of Physicians of London on Tuesday, February 9th, at 5 p.m. The chair will be taken by Sir John Tweedy, President of the Fund, and an address will be delivered by the Bishop of Oxford (Dr. Paget). The Lord Mayor of London and the President of the Royal College of Physicians will also speak. All persons interested in the Fund, whether ladies or gentlemen, are invited to attend. Full particulars as to the Fund can be obtained by communicating with Mr. George Bethel, 11, Chandos Street, Cavendish Square, London, W.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

DR. RAYNER AND THE STOCKPORT INFIRMARY.

DR. EDWIN RAYNER, Treasurer of the British Medical Association, owing to the pressure of other duties, has resigned his position on the active staff of the Stockport Infirmary. Dr. Rayner had been a member of the honorary medical staff since 1875, and for some years senior surgeon. At the meeting of the board at which Dr. Rayner's resignation was received, the Chairman expressed his sense of the loss which the hospital would suffer by the withdrawal of Dr. Rayner's active co-operation, and moved the following resolution:

That this committee receives with regret the resignation of Dr. Rayner as honorary surgeon, an appointment which he has held since 1875, and now wish to record on the minutes their warmest appreciation of the very valuable professional services which he has generously and untiringly given to the patients of the infirmary during this long period of years, services which cannot be overestimated.

That the good work done by Dr. Rayner as a member of this committee should also be made note of, as he has done much by his attendance, knowledge, and judgement to further the best interests of the institution.

That Dr. Rayner be appointed a consulting surgeon to the infirmary, and that his name be added to the list of vice-presidents, and this committee trust that his good health and energy may long enable him to help them with his advice, and to continue his interest in the Stockport Infirmary.

This was seconded by Dr. Murray, who by Dr. Rayner's retirement becomes senior surgeon. Dr. Murray said that Dr. Rayner had served as honorary surgeon for a longer period than any member who had ever been on the honorary medical staff, and it was difficult to form any estimate of the good he had done by his knowledge, judgement, and skill. The resolution, which was supported by Canon Symonds, was unanimously adopted.

MEDICAL REFEREES IN COMPENSATION CASES.

The question has often of late arisen in Manchester, Ought a medical referee for an insurance society to visit club patients or patients who have made claims under the Workmen's Compensation Act without first acquainting the medical attendant of their intention to make such visit? It is held that no medical attendant can reasonably object to such visits made simply on behalf of an insurance society, and on the side of the insurance society it is said that such visits are intended to be in the nature of surprise visits to detect possible malingering, and that notice given to the patient would defeat their object. On the other hand, it often happens that the referee himself is simply a neighbouring practitioner, and naturally some jealousy may be caused by the visit of a possible rival in a district. Besides, in some cases it would seem as if it were not so much the patient who was suspected as the medical attendant, and the visit of the referee is really to see if the doctor is correct in his diagnosis and strict enough in giving certificates of unfitness for work. Such suspicion has lately been rather resented, and the Joint Committee of the Manchester and Salford Divisions, after discussing the matter, has expressed its definite opinion that referees ought always to notify the medical attendant beforehand of any intention to make a visit on behalf of an insurance society, though it is not necessary to give the patient notice of the visit; it is felt to be only a reasonable request that the medical attendant should be afforded an opportunity of being present at any examination of his patient by another doctor.

NEWCASTLE-UPON-TYNE.

LIEUTENANT-COLONEL SIR GEORGE H. PHILIPSON.

AN honorary appointment under the new Territorial scheme which has given great satisfaction and pleasure to the medical profession in the North of England is that of Sir George Hare Philipson as Lieutenant-Colonel for the Northumberland Division. By his business qualifications and tact the colonel will prove himself to be a most useful member of the Board of Administration.

THE ROYAL VICTORIA INFIRMARY.

Dr. Thomas Moffatt Allison has been elected Assistant Physician to the Royal Victoria Infirmary. For several years past Dr. Allison has given considerable attention to the study of diseases of children.

SIR THOMAS OLIVER.

On January 14th, in the Turk's Head Hotel, there was gathered one of the largest assemblages of medical men that has taken place in Newcastle, the occasion being the annual dinner of the Newcastle-upon-Tyne Clinical Society. Nearly 130 sat down to dinner. In the afternoon, at the College of Medicine, the annual address to the society had been delivered by Sir Thomas Oliver, who chose for his subject "Caisson disease," and at the evening banquet Sir Thomas was the guest of the society. The president, Dr. A. J. Collis, was supported on the right by the guest of the evening, the High Sheriff of Northumberland, Sir Isambard Owen, and Dr. Drummond, and on the left by the Lord Mayor of Newcastle-upon-Tyne, Sir George Hare Philipson, Sir Walter Runciman, Bart., and Dr. G. H. Hume, etc. An excellent dinner having been disposed of and the King toasted, the President gave the health of "Our Guest," briefly describing his career and alluding to the services rendered by him to the Home Office and to workers in industries generally. In acknowledging the toast and thanking members for the splendid reception, Sir Thomas Oliver told the story of his coming to Newcastle thirty years ago. He did not regard himself, he said, as in any way a leader in the movement of industrial hygiene; he had simply followed where others had led, others who were even more entitled to honours than he was. His speech was at once an appeal for the appreciation of mediocrity, which after all plays an important part in the world's work, and for the better recognition of the general medical practitioner, whose rewards are not always commensurate with the services rendered to the public. Sir Isambard Owen, in an excellent speech, proposed "The University of Durham College of Medicine and the Royal Victoria Infirmary," and the toast was gracefully acknowledged by the President of the College of Medicine, and by Dr. Drummond, Chairman of the Honorary Staff of the Infirmary. To Dr. G. H. Hume was entrusted the toast of "The Lord Mayor and Corporation," which was acknowledged by the Chief Magistrate. In a speech at once learned, pregnant with truth, full of suggestion and sympathy, Alderman Richardson proposed "The Clinical Society," to which Dr. George Foggan made a neat and most appropriate reply. Mr. Ouston proposed "The Visitors," responded to by the High Sheriff of Northumberland and by Dr. Edgar Collis, H.M. Inspector of Factories, who seized the opportunity of alluding to the services rendered by Sir Thomas Oliver to the Home Office and the cause of industrial hygiene. The banquet will be long remembered as one of the largest and most successful ever held in the North of England. Too great praise cannot be given to the honorary secretary of the society, Mr. Joseph W. Leech, for to his power of organization and untiring energy must be attributed the success of the meeting.

GLASGOW UNIVERSITY CLUB.

The North of England Glasgow University Club is to hold its annual meeting in Newcastle-upon-Tyne on Wednesday, February 17th. Sir Hector C. Cameron will give an address, open to all members of the medical profession, in the afternoon at the College of Medicine, and will be the guest at the banquet of the club that evening.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

At the March meeting of the Northumberland and Durham Medical Society, an address will be given by Sir Lauder Brunton, Bart., on "The Treatment of Heart Disease," and in the evening a dinner will be held.

LEEDS.

THE ADULTERATION OF MILK.

The city and county analyst, Mr. T. Fairley, in a report for the four months ending December 31st, 1908, states that 153 samples of milk were submitted for examination, and 41 samples found to be at fault. In the case of 33 there was added water, in 5 there was a partial extraction

of fat, in 2 both these vices prevailed, and in 1 case there was an addition of boric compounds; the proportion of adulterated specimens was 26½ per cent., as compared with 16 per cent. for the fourth quarter of last year. In common with these figures, one must note a very flagrant instance, in which a farmer was prosecuted before the Leeds stipendiary within the last few weeks. Mr. Fairley had certified the milk as containing 28 per cent. of added water, and the case was adjourned pending an analysis by the authorities at Somerset House. As this showed a percentage addition of 29, the defendant was convicted. In view of the fact that three previous convictions were on record, the defendant having been fined £5 in 1904, £10 in 1906, and £20 again in 1906, the stipendiary imposed a fine of £30 and costs, and warned the defendant that his next conviction would be followed by a fine of £100, which is the maximum penalty. One cannot but feel that in the case of hardened offenders a term of imprisonment without the option of a fine would be an appropriate punishment; if the law does not admit of this, the power of the authorities should be strengthened.

CORONER'S INQUESTS IN LEEDS.

During the year 1908 the number of inquests held in the coroner's court was 687. Of these, 425 were in the case of males and 262 in that of females; 26, 14 male and 12 female, were in the case of children under 16 years of age. In 5 cases a verdict of wilful murder and in 3 cases a verdict of manslaughter was returned. Suicide when of unsound mind was the verdict in 39 cases, and in 3 cases the verdict was *felo de se*. Nine men and 6 women were found to have died from the immediate effects of excessive drinking. Accidents and misadventures accounted for 258, and 6 were cases of drowning. In 115 cases in which the facts in connexion with death were communicated to him the coroner decided that no inquest was necessary. In connexion with these last figures it would be well if medical men would bear in mind that the responsibility of deciding whether an inquest should or should not be held rests with the coroner, and in any case in which there seems the slightest doubt in the matter the facts of the case should be laid before the coroner. Perhaps the medical profession of Leeds is unusually fortunate in having a man of such large experience, good judgement, and courtesy and consideration as Mr. J. C. Malcolm to deal with as coroner.

THE GENERAL INFIRMARY.

Miss Lownsbrough, who has acted as housekeeper at the General Infirmary since 1875, has tendered her resignation to the board. This is an announcement which will be noted with sympathetic interest by many generations of former residents, for every one will agree that throughout her long connexion with the infirmary Miss Lownsbrough has done everything in her power to render the term of office of the members of the resident staff a period of their lives to which they can look back with grateful recollections. Miss Lownsbrough will carry with her the best and most cordial thanks of many men who have long left the infirmary, and they will wish her long life and every happiness in her retirement.

WEST YORKSHIRE.

BRADFORD ANTHRAX INVESTIGATION BOARD.

The third annual report of this board for the year ending October 31st, 1908, is one of great interest. The board was originated by the Bradford Chamber of Commerce, and is financed by many prominent members of the Bradford trade, with the assistance of a grant of £50 a year from the Treasury. It may be interesting to note, too, that Dr. T. M. Legge, H.M. Chief Medical Inspector of Factories, made a personal contribution to the fund, "as a mark of appreciation of the value of the work which the board has already done." Professor F. W. Eurich is the board's bacteriologist, and superintends all the investigations made on its behalf. During the year under review 435 samples of wool, hair, and dust were examined. Anthrax bacilli were cultivated from 21 samples, of which 20 were blood-stained. During the past three years nearly 600 samples of wool, hair, and dust—not blood-stained—have been examined for anthrax with

negative results, while 139 blood-stained specimens have been tested, with the result that anthrax germs were found in 14.4 per cent. Dr. Eurich consequently points out that blood-stained material and the dust arising from it, with its scales of dry blood, are the means of spreading anthrax spores, and may be called the "carriers" of anthrax. This is perhaps the most valuable of the deductions made during the past year. If blood-stained fleeces and wool can be eliminated from the materials handled by the workmen anthrax will probably become a negligible quantity. With regard to the effect of washing and disinfection of blood-stained material, the fact that many cases of anthrax had occurred in men who manipulated the wool after it had been dried and washed is explained as due to the difficulty of washing out blood. Blood can easily be recognized even after washing, and the blood-stained fibres are still capable of giving off a fine germ-laden dust. Previous steeping in cyllin or Leach's germicide appears neither to facilitate nor to retard the removal of blood by subsequent washing; solutions of formaldehyde, on the other hand, fixed the blood to the fibre still more firmly. Formaldehyde, cyllin, and Leach's germicide fail to kill anthrax spores within the matted blood-stained fibres in the time in which they produce this result when acting on spores simply suspended in water or artificially dried on to the fibre. Formaldehyde, 2 per cent., will kill anthrax spores under the latter conditions in two hours, but anthrax bacilli could be cultivated from blood-stained mohair after steeping *en masse* without interruption for five days. Cyllin which will kill anthrax spores in water or dried on to wool in a 1 per cent. solution in one hour failed to kill them even in a 2 per cent. solution at the end of that time when a piece of matted blood-stained wool was placed in a basinful of the disinfectant. The actual time required by cyllin and Leach's germicide to kill anthrax spores under these conditions could not be determined from want of suitable standard material.

The attempt made to disinfect unopened bales of wool by electrolysis did not produce satisfactory results. Numerous statistics are given connected with the imports of wool, mohair, camel's hair, etc., and the relative dangers of the different classes of materials. Details of anthrax cases or suspected anthrax cases that have occurred during the past year are also given.

The whole report reflects the greatest credit on the board, and Professor Eurich is to be congratulated on his untiring scientific efforts to devise means for stamping out this disease.

LIVERPOOL.

THE SCHOOL OF TROPICAL MEDICINE.

DR. J. O. WAKELIN BARRATT and DR. WARRINGTON YORRE, who left England on August 12th, 1907, to investigate blackwater fever, have returned to England, having spent fourteen months in Nyassaland. The expedition was provided with an extensive equipment for pathological and chemical study, and unusual opportunities for the study of blackwater fever presented themselves. Nearly all the cases occurring in the Protectorate during the period came under observation. Every assistance was given by the Government Medical Staff and by the Shire Highlands Railway Company. Two hospitals were available for the reception of cases of blackwater fever—the railway hospital at Luchenza and the Government Hospital at Blantyre, the latter being exceedingly well equipped. One of the members was attacked with dysentery, but otherwise the health of the expedition was good. The expedition was financed in equal shares by the Colonial Office and by the Liverpool School of Tropical Medicine.

THE NEW DENTAL HOSPITAL.

The foundation stone of the new dental hospital was laid by the President of the hospital, the Earl of Derby, on January 16th, the Lord Mayor presiding. Lord Derby, in the course of his remarks, said that it was not possible to over-estimate the harm done by bad teeth to the constitution of boys and girls. Many men were sent back from South Africa on account of their teeth, but many suffered from their teeth who were not sent back. It was the desire of those founding the hospital to bring to the doors of the poor the best that dental science could do, and he believed that the effect of their work and of the generosity

of the subscribers would be very great on the health and life of coming generations. Mr. W. H. Gilmore, the Warden of the hospital, said that he believed the new building had been designed on the most economical and efficient lines; it was rather remarkable that at the time they would be opening it they would be celebrating the jubilee of the institution. The dental school, opened in 1876, had last year a record number of students. As many as 27,000 patients attended during the year. The true business of the hospital was to save teeth, not to extract them, and over 16,000 teeth had been saved—a number which for the first time was in excess of those extracted.

The site of the new building is at the corner of Pembroke Place and Boundary Place, within two or three hundred yards of the university and the Royal Infirmary. The estimated cost of the building and equipment is £10,000, of which three-fourths has been already given or promised.

WALES AND MONMOUTHSHIRE.

A GREAT TRUNK SEWER.

ONE of the most complete schemes of sewerage ever carried out has just been finished in the Western Valleys of Monmouthshire. It is designed on the separate system—that is, the sewage is kept separate from the rainfall as far as possible. The sewer is calculated to provide for a population of 200,000, which is ample for the Western and Sirhowy Valleys, but is capable of enlargement. At present this scheme comprises 35 miles of sewer, while the Sirhowy branch, when added, will make it nearly 50 miles. The work was commenced on October 5th, 1905. It has cost £236,000, the original contract being for £210,121, certain alterations and extra work having been undertaken. The Sirhowy section was commenced in April, 1908, and will probably be completed in about eighteen months. The engineers for the whole scheme are Mr. Baldwin Latham and Mr. George Chatterton of Westminster. At the outset there was considerable opposition to the trunk scheme, various other schemes being put forward as equally efficient and less costly, in particular the septic tank method. The scheme resembles a huge three-pronged fork. The handle of the fork runs from the outfall in the Bristol Channel, about two miles from the mouth of the Usk, up to Crosskeys. From this point the Sirhowy branch runs to Tredegar, and a parallel to this is a sewer tapping Abercarn, Newbridge, Crumlin, and Aberbeeg. At the latter place there is another division, one branch running to Ebbw Vale, and a parallel branch through Abertillery and Blaenau, terminating at Nantyglo. It is intended, however, some time in the near future to connect up Brynmawr with Nantyglo. The three branches take their courses from the three rivers—Sirhowy, Ebbw, and Ebbw Fach. The pipes at the northern portion commencing at Nantyglo and the other termini are 12 in. in diameter, and gradually increase in size as the valley is descended. At Aberbeeg, the junction of two of the branches, the diameter is 2½ ft., at Newbridge 2½ ft., at Risca 3½ ft., and at Bassaleg 3½ ft. Near this point they are connected with an 11-ft. tank sewer, which is three quarters of a mile long, and has a capacity of 3,000,000 gallons. In this tank sewer the sewage is shut back until the time comes for its discharge into the Bristol Channel. From the tank sewer to the outfall, a distance of nearly three miles, the sewer is about 3½ ft. in diameter, and is made of cast iron pipes. A special point in the scheme, which offered considerable difficulty, was the tunnelling, more than a mile in length, under Ford's Lane, at Bassaleg, where the road and railways had to be crossed. A considerable quantity of water was met with in the construction of this tunnel. Owing to the narrowness of the valleys in a great many places along the routes the only possible situation for the sewer pipes was in the bed of the river Ebbw. At these places the sewer is made of steel pipes surrounded with concrete. The most difficult portion of the scheme was naturally that part of the outfall below high-water mark in the Bristol Channel. This is about 1,030 yards in length, and had to be carried out between the tides, with the exception of the extreme point of the outfall, which was completed by means of divers. The outfall is somewhat remarkable from the fact that the whole of it is laid with

at least 4 ft. of covering over the top of the pipes, so as not to form any obstacle to navigation, a 4-ft. trench having been made on the foreshore for its accommodation. The point of termination is marked by a can buoy, which forms a conspicuous mark for vessels. The outfall apparatus comprises a penstock chamber fixed in the sea-wall of the channel. Here the discharges will be regulated by an electrical recording apparatus, which will record the time when the valves are actually open and shut. According to the Act of Parliament the discharging of the sewage into the sea will take place in the time elapsing between one and a half hours before high tide and three hours twenty minutes after high tide. The sewage will be "stored back" during the remaining portion of the tide. Whilst discharging the sewage will be taken away to sea by the ebb tide. Experiments have shown that a very short distance from the outfall, owing to the enormous flow of water in the Severn estuary, all chances of contamination are removed.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

HISTORY OF MEDICINE.

THE first of a course of eight lectures on Medicine among the Ancient Egyptians, Greeks, and Romans was given in the Forensic Medicine Theatre of the University of Edinburgh on Wednesday, January 13th, by Mr. John D. Comrie, M.A., B.Sc., M.B., the first holder of the lectureship on the history of medicine in this university.

Dr. Comrie said that in preparing a course of lectures on the history of medicine he had encountered at the outset several difficulties. In the first place he must show that the commonly accepted notion regarding ancient medicine, which believed it to be a mass of foolish traditions and childish remedies, was quite erroneous. With all their follies and shortcomings, among the practitioners of the healing art, even in the most distant past, were men of skill and noble character. The history of medicine must be treated as a branch of the history of civilization, for the strange practices which they found in medicine at various epochs were often simply a reflex from the manners and ideals of society at the time. He intended in this preliminary course to treat of the foundations of the Western medicine from the earliest time to the declining days of the Roman Empire.

With regard to Assyrian medicine, the medical procedures of the peoples inhabiting the Euphrates basin were closely bound up from about 1500 B.C. onwards with those of Egypt. In Babylon the doctor was mentioned as early as 2700 B.C. and of the Code of Laws promulgated by Hammurabi, King of Babylon, about 2200 B.C.; some nine referred to the remuneration of medical practitioners for the treatment of various diseases. From incidental references it appeared that the operation for cataract was frequently performed, and that unqualified persons attempting surgical operations unsuccessfully were to be punished by having their hands struck off. The highest fee allowed for the successful treatment of a severe wound was equivalent to 25s. of our money, and apparently if the patient did not recover the doctor was not paid. When Nineveh was destroyed in 606 B.C. the library of King Assurbanipal, consisting of some 20,000 books of cuneiform characters inscribed on baked clay tablets, was left among the ruins. Out of these nearly 1,000 consisted of medical works which had come down from a very early epoch. In these such substances as sesame, olive and castor oils, syrup of dates, honey, and salt could be identified as favourite remedies; fasting was very frequently prescribed. Several letters written by consultants to one another or to their royal patients had also been found, and from these they found that quarrels among Assyrian doctors were by no means unknown. A favourite method of seeking medical advice in ancient Babylon was to lay the sick person in the public square to talk with the passers-by; any of these who had suffered from symptoms of a similar nature were able to give him encouragement and describe the remedies which had been useful to themselves.

Long before the time of the Exodus, medical practitioners in Egypt had reached a position of dignity and

usefulness; and about 1500 B.C., while Egypt was at the zenith of her glory, and while Israel was still a sojourner within her borders, a very definite idea of their social position and the methods of treatment adopted could be formed. Of the papyri from which this knowledge was derived, by far the most important was that brought to Germany by Professor Ebers in 1873. From this many of their ideas regarding physiology and the nature of disease were known, and many of the substances used as remedies could be identified. Among the latter were such familiar substances as magnesia, lime, iron, soda, nitre, and vermillion; peppermint, fennel, thyme, cassia, caraway, juniper, cedar-wood oil, and turpentine, gentian and other bitters; opium, squills, colchicum, mustard, onion, mandrake, and henbane; linseed, castor oil, frankincense, myrrh, and yeast. The names of many other drugs it was still impossible to translate. Wounds were treated by means of a plaster of crocus and essential oils, and various external applications, like poultices; inhalations and massage were in common use. Tumours were removed by means of beautifully-shaped bronze knives, and bleeding was stopped by the cautery. For the treatment of ophthalmia applications were employed, and the eyelids were manipulated by copper forceps, almost identical with the steel ones of the present day. The sacredness of the human body did not permit of amputation, except of hopelessly shattered limbs, but the fractures of bones were set with neatness and precision in splints of wood or plant fibre wrapped round by linen bands. The shapeliness of broken limbs after treatment by Egyptian doctors was moderately good, but did not reach the success of the Greeks who, in Plato's time, seem to have anticipated almost every device known to this branch of modern surgery. The social position of the medical profession in ancient Egypt had given rise to considerable discussion. The physicians undoubtedly belonged to the priestly class, though they were not priests themselves. Six sacred books on medicine were kept in the temples of Thath by priests, who had to know their contents by heart. In some cases medical treatment had to conform to the sacred original. The embalmers were of a lower and quite different class from the physicians, although the Hebrew applied the general term "healer" to them both. Many of the physicians of early Egypt reached a high place as the friends and councillors of Pharaohs, and one, who lived apparently in the time of the Third Dynasty (3500 B.C.), was in later times even deified and worshipped at Memphis and other places. All these facts sufficed to show that the assistance of a class trained in the art of healing was eagerly sought in the lands where the dawn of our civilization began. When it was remembered that the time of which he had spoken was a period of slow transition from an age of bronze to one of iron, it would be seen that this art occupied a position of high efficiency as compared with others, and of great advancement in the general scheme of human knowledge.

A NEW SPHYGMOMANOMETER.

At a meeting of the Royal Scottish Society of Arts held in Edinburgh on January 11th Dr. G. A. Gibson described a new sphygmomanometer, for determining and giving a graphic record of the systolic and the diastolic blood pressure in man. The principle of circular compression is utilized to estimate the systolic blood pressure, while at the same time the diastolic pressure is measured. The instrument has a mercurial manometer, the lumen of which is exactly that of the ordinary physiological kymograph. The air in the armlet can be increased, and the pressure on the limb therefore raised, by means of a large syringe, quickly or slowly according to requirements. By means of a valve the pressure may be also lowered quickly or slowly. The pulsations of the artery below the point of compression are recorded by means of a transmission sphygmograph.

SCARLET FEVER EPIDEMIC IN ABERDEEN.

Professor Matthew Hay, Medical Officer of Health, states that the present scarlet fever epidemic is the worst experienced in Aberdeen since 1897, when there were over 1,000 cases. The present epidemic made its appearance towards the end of September, 1908, and up to the present there has been an average of between 50 and 60 cases per week. The cases are distributed all over the town, although much more numerous in some wards than in others, but in none

is there complete immunity. The severity of the present outbreak is to some extent due to the fact that there has been very little scarlet fever in the town for several years, and it was quite in accordance with the expectations of the sanitary and medical authorities that the epidemic should be of widespread dimensions. The attack is, however, fortunately not of a very virulent type, and the death-rate is very low. It will be noted that all over Scotland there is just now a great deal of scarlet fever. Diphtheria is also very prevalent, but not nearly so much as a few weeks ago. There are also many cases of measles in the town, as many as of scarlet fever; but measles is not now a notifiable disease, so the exact number cannot be stated by the authorities. Whooping-cough is also common, and has already caused a number of deaths.

INTRODUCTION OF PROFESSOR DEAN.

The classes at Aberdeen University were resumed after the Christmas vacation on January 12th with an almost full attendance of students. The chief feature in connexion with the resumption of the winter session work was the introduction of Professor Dean, the new occupant of the Chair of Pathology. Principal Lang introduced the new professor to a crowded and enthusiastic audience, which included Dr. Angus Fraser, Professors Matthew Hay, Reid, Cash, and MacWilliam, Dr. George M. Duncan (who conducted the work of the Chair most ably during the first half of the winter session), and several members of the Royal Infirmary staff and of the junior teaching staff of the university. In welcoming Professor Dean the Principal paid an eloquent tribute to the late occupant of the Chair, Professor Hamilton, in course of which he said no one who had ever been brought within his circle of personal influence could forget a presence so vital, so magnetic, and so full of vivacity, and no one who had studied in that class-room could fail to remember a teacher remarkable for the lucidity of his exposition, a most kindly yet most thorough instructor. Every recollection of the laboratories that he fitted up and equipped was associated with him who there demonstrated to his students and there conducted and completed the researches that had made his name known far and wide. They all hoped that Professor Hamilton would yet recover strength and enjoy a long and tranquil evening-tide. The Principal then in fitting terms introduced Professor Dean, referring to his distinguished career and his qualifications to continue the great traditions of the Chair and to add to the lustre, already brilliant, that rested upon it.

Professor Dean on coming forward got a great reception from the large audience, and his opening remarks, in which he referred to his old teacher, were listened to with deep interest, and will be read with approbation by Aberdeen students all the world over. He said

The feeling of pride and pleasure that I naturally have in the honour conferred on me by my appointment is shadowed by the thought of the circumstance which led to the necessity of a change in the occupancy of this chair. The severe loss that the university has sustained by the retirement of Professor Hamilton is, I am sure, the thought uppermost in all our minds. Before Professor Hamilton's time, although excellent work had been done here in several branches of pathology, it may be said without exaggeration that the teaching of pathology as a scientific subject was unknown in Aberdeen. On his appointment as the first occupant of the Erasmus Wilson Chair of Pathology in the University he had before him both a great opportunity and a great task. The admirable manner in which he made the most of the opportunity and carried through the task is attested on all hands. He organized and equipped the department of pathology both in the University and in the Royal Infirmary in such a manner as to make it a credit to any university or institute. His conduct of the department on all its sides put the Aberdeen School of Pathology in a leading position in this country and brought distinction to the University. Not only did he do this, but he did much work for the good of the community in the North of Scotland. It was largely through the agency of his department that the public benefited by newer methods of diagnosis and treatment which had a bacteriological or pathological basis. For example, I recall that during the period when I was his assistant he brought into use in the North of Scotland the bacteriological diagnosis of diphtheria and of typhoid fever, and the examination of water by bacteriological methods. Professor Hamilton's devotion to scientific research has been tireless, and his work, by its high quality and thoroughness, has gained the respect of his fellow workers everywhere. His *Textbook of Pathology* for many years has been regarded as the most important work of that character on the subject of pathology which has appeared in the English language. His investigations have embraced a wide range of subjects. I may

mention his works on the nervous system, on the healing of wounds, on bronchitis, on tuberculosis, and on the infective diseases of sheep, to which in recent years he has given so much attention. That these have been regarded as important contributions to scientific knowledge is attested by the fact that his work has gained the approval of the highest adjudicating body in this country—the Royal Society—which conferred on him the honour of a Fellowship—a distinction which gave much pleasure to many of his friends and old students throughout the world. Professor Hamilton's teaching powers were of the highest order, as I can now attest from a fairly wide experience of teachers at home and abroad. As a lecturer he had the power of arousing and retaining the interest of his students in the subject. His vigour, his enthusiasm, his lucidity created a deep impression on every one with whom he came in contact. He brought before the students matured judgement, the result of a careful analysis of the subject matter, thus saving them much confusion of ideas. He spared no pains in making his lectures models of scientific exposition. The value of experimental methods was constantly kept before his pupils. He trained those that came under him to become observers, and enforced on them the necessity of accurate scientific method. He could not tolerate anything slipsidish, and I feel convinced that many have benefited greatly by this characteristic, though at the time it may be feared they did not realize its value. Professor Hamilton's position as a teacher in the pathological world of Great Britain is unique. There is certainly no one in this country who has so many pupils occupying important positions all over the world as teachers of pathology and as scientific investigators. London has several, and others are to be found in Edinburgh, Cambridge, Manchester, Birmingham, Belfast, Glasgow, Hong Kong, the Malay Peninsula, to mention a few of the positions which occur to me. Perhaps his greatest achievement, however, is that by his teaching of pathology he has laid the foundation of a scientific knowledge of medicine in a great number of young men who as the result of that teaching, when they have gone out into the world, have been able to bring into their ordinary medical practice a higher quality of service to their fellow-men. Personally Professor Hamilton, essentially a generous-minded and warm-hearted man, has gained the admiration and affection of many generations of students. I am sure we all sincerely hope that an improvement may take place in the state of his health, so that he may have that period of restful happiness in his life which he has so richly earned. What I have said will indicate in some slight degree how deeply I realize that it will not be easy for me to follow in the footsteps of my predecessor. I feel sure, however, that I may rely on the generous sympathy of my students, many friends in the medical profession, and of my colleagues, many of them my old teachers.

Professor Dean then proceeded to deliver his opening lecture on "The Conveyance of Infective Diseases in the Light of Modern Research." Professor Dean has been appointed Pathologist to the Aberdeen Royal Infirmary in succession to Professor Hamilton.

A SCOTTISH UNIVERSITY WOMEN'S SUFFRAGE SOCIETY.

A meeting of the Committee of Women Graduates of the Scottish Universities (Parliamentary Franchise) was held on Saturday, January 16th. The meeting, which was representative of the Universities of St. Andrews, Glasgow, and Edinburgh, was of the Provisional Committee formed on the preceding Saturday at the last meeting of Scottish Women Graduates. A report was submitted by the sub-committee, which had drawn up a scheme for the formation of a university women's suffrage society. It was agreed that such an association should be formed, on a non-party basis, to assist in promoting the cause of women's suffrage. The object of the society "is to obtain the Parliamentary franchise for women on the same terms as it is, or may be, granted to men." The aims of the society are to hold meetings in every town and village in Scotland; to send a petition to the House of Commons from every such meeting at which is passed a resolution in favour of the enfranchisement of women, and to induce public bodies and societies to do the same; to canvass every household in Scotland; to secure statements on the subject from every member of or candidate for a Scottish constituency; to ask, or arrange to have asked, preferably by electors, questions on the subject at every political meeting addressed by a member or a candidate in Scotland; to work at Scottish Parliamentary elections; to place a women's suffrage organizer in every constituency in Scotland, beginning with the four university towns; to select, compile, and distribute suffrage literature, and to correct mis-statements in the Press; to encourage literary, social, and political clubs; to hold debates and lectures on the subject; to induce teachers, speakers, and lecturers on the subject to point out to their hearers that the principles of liberty apply as much to women as to men. The membership of the Society is to be open to graduates—women

of any university and women on the *Medical Register*; all others in sympathy with the movement may become associates of the society.

Ireland.

[FROM OUR SPECIAL CORRESPONDENT.]

IRISH IN THE NATIONAL UNIVERSITY.

The struggle which has been originated by the Gaelic League in reference to Irish in the new National University still proceeds. The National newspapers are flooded with correspondence, *pro* and *con*, and the county councils and other public bodies continue their contributions of supporting resolutions.

The question has become one of serious importance, for many look upon the proposed requirement that all students must know Irish as a fatal measure if adopted. There have been rumours as to the views of certain members of the Senate, but there has been especially an uneasy feeling that the timidity of the majority must end in the acceptance of the compulsory policy. The newest development is the pronouncement of the Roman Catholic Episcopal Standing Committee, which appeared in Dublin on Wednesday last. It is signed by Cardinal Logue, the Bishop of Waterford, and the Bishop of Cloyne. They declare their profound interest in the work of the National University and its colleges. They have no doubt that Irish Catholics, no matter how slender their resources, will provide from the outset "the advantage of the highest education in the truths of religion and of the necessary facilities for the practice of divine worship." The Committee notice with deep pain "that the Senate is receiving in the columns of the public press treatment which is neither creditable nor servicable to the nation." And they proceed:

Whether it be good for the Irish language movement, and good for the new university to make Irish compulsory is a question for fair argument. For our part, we look forward to the day when the Irish language will again be spoken throughout the country, and will in consequence become largely the medium of instruction in the constituent colleges. But to reach that stage we consider that by far the best means is to set up in the colleges bright centres of Gaelic study that will, by their light and by their rewards, attract young Irishmen within the sphere of their Irish influence. The progress of Irish in our seminaries and in numbers of the intermediate schools of the country, so far from being an argument for compulsion, shows what the voluntary system, under our constant encouragement, has hitherto done, and what no doubt it will do still more successfully in the colleges of the new university. It is quite possible that in existing circumstances compulsion, instead of being a help, would be a hindrance to the language movement. It certainly would drive away from the university not a few students who, if once brought under the influence of the Gaelic school of a constituent college, would grow up good Irishmen. Entertaining these views, and deeply concerned alike for the revival of our national language and for the success of the National University, we deem it right to put them on record for the information of our people.

This declaration will cause much heartburning, but the influence of the bishops is such that the question in dispute is probably settled.

CONVOCATION OF THE ROYAL UNIVERSITY.

A meeting of Convocation of the Royal University convened for Tuesday last, fell through owing to the want of a quorum of thirty. While waiting for the expiration of the recognized time the graduates present discussed a motion proposed by Mr. Frank Hugh O'Donnell, M.A., ex-M.P., expressing regret for the passing of the Royal University, and wishing success to the new universities established in its place. Mr. O'Donnell regretted that anything should happen to weaken the ties between North and South, but hoped that notwithstanding the reality of patriotism would flourish between them, and that the bonds of common love for Ireland would prove stronger than all disintegrating influences. He condemned the decision to exclude extern students. He thought it was an infamous thing to deprive thousands of young Irishmen of the stimulus and reward of studies in their own Irish homes. He congratulated the University of Belfast on the admission to its Senate of representatives of the graduates. On

the other hand, in the National University in Dublin only one-fourth or one-fifth of the governing body would be representatives of the graduates, the triumphant majority being Crown nominees. He hoped their brethren in the North would use their utmost efforts to raise the rest of Ireland to the same level of academic self-government and academic freedom which was to be enjoyed by the graduates of Belfast.

Dr. McWalter, who seconded the motion, said that if Convocation had been given more power it would have been unnecessary to create two new universities, and thus cut off the North from the South of Ireland.

Dr. King Joyce alleged that there had been cases in which honours had been refused to candidates because some of the senators had private feeling against them.

Sir William Thomson, C.B., defended the Senate from these charges, and was supported by the Chairman (Dr. Leslie, Belfast), Sir James Creed Meredith, Mr. F. Hugh O'Donnell, Mr. Charles Doyle, K.C., and Dr. Condon, Barrister-at-Law.

The motion was carried without opposition.

JUDGE AND DOCTOR.

An Irish doctor writes with reference to the incident related under this heading in the JOURNAL of January 16th, page 177:

Some time ago I had to attend at quarter sessions at which this judge presided, and I too was witness in an assault case. There is no railway, so the journey—about twelve or thirteen miles to the quarter sessions village—had to be made by road. I was detained all day in anticipation of the case being called, and had to return again on the next day and wait till the afternoon, when the trial came on. I did not, like Dr. Tierney, stipulate that I would like to have my fee arranged before being sworn, with the result that a guinea for the doctor was the total amount allowed in payment for my evidence, and this entailed two days' waiting, besides journeys, hotel expenses, and my liability for a guinea a day for my locumtenent in case of any urgent Poor-law dispensary call during my absence. Considering the whole circumstances it would be difficult to say which was harder hit—Dr. Tierney for contempt of court or I for respecting it. Naturally, after such treatment one can have very little ambition so to further the ends of justice again. Perhaps you would be so good as to tell me the best course to adopt on getting a summons to attend and give evidence at this judge's court in future?

It will be remembered that Dr. Edward Tierney, who was in a civil court (the Clones Quarter Sessions) apparently by accident, was called upon by the judge to give evidence in an action for assault. He refused on the ground that no fee was paid or promised. The judge then fined him £2 for contempt, and ordered him out of court when he attempted to speak. Although he exercised his power in a harsh manner, the judge appears to have been technically in the right. Any one who has come to court without fee or conduct money must give evidence if called upon. In practice, however, we have always understood that in courts of civil jurisdiction the judge will protect a witness by refusing to compel him to be sworn when his lawful fee and conduct money is not paid. Unless the proper fee and conduct money are tendered, a witness who absents himself cannot be committed for contempt. In the case put by our correspondent he might have refused to attend unless he was paid in advance; and having regard to the rule about conduct money, we see no reason to prevent him from insisting on payment of the cost of a conveyance both ways, his hotel expenses for one night at least, and the usual daily fee which is paid to professional witnesses under the rules of court. That, at any rate, would be the proper course for a medical witness to adopt in England. Having attended court without insisting on any payment, his position would be the same as that of Dr. Tierney, who was committed for contempt.

ALCOHOLIC PATIENTS IN THE BELFAST WORKHOUSE INFIRMARY.

Dr. Fulton, one of the visiting medical attendants of the Poor-law Infirmary, has lately made an important and instructive report to his committee dealing with the number of alcoholic patients yearly admitted to the infirmary. Some of these patients are actually in delirium tremens on admission; some develop it immediately afterwards. The law allows the guardians to make a charge of 6s. 5d. a week, but this sum is ridiculously small. As these patients are one of the most dangerous and expensive kind

Dr. Fulton urges that the charge should be three guineas a week, and adds that many of the patients were able to pay this sum. Last year 283 male and 203 female alcoholic patients were admitted; this is exclusive of cases admitted to the surgical wards and subsequently transferred to other wards. Many of these patients were parents, and their homes were going to desolation. This system, says Dr. Fulton, of admitting them without any restraint whatever, is simply manufacturing by the hundred paupers who will in years to come fill, and be permanent inmates of, the workhouses and asylums. The report is being considered by the guardians.

THE BELFAST MUNICIPAL ELECTIONS.

One new medical councillor has been added to the Belfast City Council. Dr. John McLroy is a well-known and popular medical man, and he has been returned unopposed for Dock Ward, in the room of Sir Thomas Dixon, Bart., who retired. Dr. McLroy was practically adopted by all parties, and will be one of the most trusted members of the Council. Dr. Brown and Dr. Henry O'Neill have been re-elected without opposition, although the latter was threatened with it in the earlier stages. Dr. James Williamson was opposed at the polls, but came out victorious with 1,674 votes against his opponent's 64, raising his majority from 400 at the last to 1,510 in this election. The profession generally congratulates their medical brethren on their success, and feels sure that medical interests and public hygiene will be safe in their hands.

Special Correspondence.

PARIS.

Treatment of Cancer of the Skin and Mucous Membranes by Radium.—The Legion of Honour.

PROFESSOR GAUCHER recently devoted a clinical lecture at the St. Louis Hospital to the treatment of cancers of the skin and mucous membranes by radium, which has been carried out in his wards for the last year by Dr. Dominici. The radiation of radium consists of rays called respectively alpha, beta, and gamma. The first two are corpuscular rays formed by the projection of electrified particles of matter, the alpha being charged with positive and the beta with negative electricity. The gamma are vibratory rays, consisting in the propagation of a commotion of the ether caused by the production of alpha and beta rays, which results from the disintegration of atoms of radium. The gamma rays have the greatest, the alpha rays the least penetrating power. The activity of radium—that is, the intensity of its radiation—is measured either directly, in electrical unities, or relatively, taking the activity of uranium as the unity.

Apparatus.—Two kinds of apparatus are used in radium-therapeutics: (1) Supports of metal or cloth on the surface of which a pulverized radium salt is spread and maintained by means of some adhesive substance, generally Danne's varnish. The bromide, carbonate, or more often the sulphate, of radium is used pure, or mixed in varying proportions with an inert salt, the bromide, carbonate, or sulphate of barium. The metallic supports are in various forms—discs, quadrilateral plates, balls, ovoids, or cylinders—according to the conformation of the part to which they are to be applied. They can thus be applied to flat or convex surfaces, within cylindrical cavities, such as the external auditory meatus; they can be insinuated beneath the eyelids, etc. (2) Apparatus with free salts of radium, contained in tubes or ampoules of glass, the salt of radium being pure or mixed in varying fixed proportions with a barium salt. In describing an apparatus in which the salt is stuck on metal or cloth it is necessary to know (1) the surface on which the radium salt is spread; (2) the weight of the salt; (3) its theoretical and effective activity. Thus a metallic or cloth square whose side measures 2 cm., on which is stuck 1 cg. of pure radium sulphate, would be described as apparatus: S. (surface), 4 cent. cubes; W. (weight), 1 cg.; A. (activity), 2,000,000. In practice, however, the radium salt is mixed with barium salt, and the activity of the mixture is expressed by the respective proportions of radium and barium; thus the apparatus generally used in treating epitheliomas are said to be of A. 500,000, because

the radium-producing powder is a mixture of one part of a radium salt with three parts of a barium salt. This is the theoretical and not the real activity, which may be modified by various causes—for example, the absorption of a part of the radiation by the varnish, the superposition of the layers, etc. The activity of metal apparatus is less than in apparatus made of cloth, as in the former the grains of radium are completely embedded in the varnish, whereas in the latter the grains stick out of the layer of varnish. A very useful apparatus containing the free salt is a glass cylindrical ampoule containing 9 cg. of pure radium salt; this is placed within a silver sheath of 1 mm. thickness.

Application.—The apparatus may be used in the treatment of epitheliomas in one of two ways: (1) By utilizing the radiation as it is furnished by the apparatus, or after having filtered it, allowing all the gamma rays, and a large portion of the beta rays to pass; if not also the alpha rays. (2) By filtering the radiation so as to suppress the alpha rays, almost all the beta rays, and the less penetrating fraction of the gamma rays. This is the Dominici's method of ultra-penetrating radiation. The two methods have the same rules as to the protection of healthy tissues from the radiation, and the asepis of the diseased parts; to protect the neighbouring healthy tissues, lead slides or plates covered with tarlatan are used; asepis of the diseased tissue is necessary to prevent erysipelas or lymphangitis.

Method of Composite Radiation is the name given to the first of the above, since it brings into play the totality or the largest portion of the different effective radiations of the apparatus used. (a) These are used without the interposition of any screen save a thin piece of gold-beater's skin to protect the apparatus from organic liquids; (b) the radiation is partially filtered by means of substances with relatively slight absorbing power, such as rubber, cotton-wool, tarlatan, or aluminium, which is one of the least dense metals, and consequently one of the most permeable to the radiations. Composite radiation is used in two ways, either to prevent or to cause the production of massive sloughs. The first way, devised by M. Danlos, consists in placing the apparatus on the tumours during a very short time, for example, ten minutes, and frequently repeating the applications. Neoplastic tissues can thus be caused to undergo retrogression without causing any scar. The method is excellent, but is only applicable to epitheliomas of small dimensions, and very sensitive to the radiations. The duration of the treatment is extremely long, and certain cancers resist its action. The destructive method, used by MM. Louis Wickham and Degrais, consists of placing on the tumours apparatus of A. 500,000 and leaving them *in situ* for six to ten hours on the average for each zone of application. These applications are completed in two or three sittings, which at intervals of one or several days, after which the treatment is stopped. The effects are shown by an intense reaction of the neoplastic tissue followed by the production of a slough, which falls off about the sixth week, leaving a red and squamous skin surface, which eight or ten weeks after the end of the treatment takes on the appearance of a white, supple, and regular cicatrix. Drs. Wickham and Degrais advise, before applying the radium, that the diseased part should be carefully cleaned, removing the crusts and making the part aseptic.

Method of Ultra-penetrating Radiation consists (1) in the filtration of the radiation, only keeping the ultra-penetrating rays of Dominici; (2) in varying the intensity of the radiation thus obtained. The ultra-penetrating radiation of Dominici is defined relatively to the nature and the thickness of the screens traversed to the radiation of the radium itself, and to the x rays. Dominici describes as ultra-penetrating rays those which have traversed leaden plates of five-tenths to several millimetres of thickness. The rays thus filtered are essentially the gamma rays and an infinitely small quantity of beta rays. The ultra-penetrating gamma rays are rays which have traversed metallic screens which intercept the great majority of ordinary x rays. The advantage of suppressing the alpha rays, the great majority of the beta rays, and a fraction of the gamma rays, which correspond to the ordinary x rays, consists in the remarkable innocuity of the ultra-penetrating radiation which remains, an innocuity which

does not interfere with its healing properties when applied to gangrenous, inflammatory, and neoplastic processes.

Apparatus.—Dominici uses very powerful apparatus surrounded by plates of lead, silver, or gold the thickness of which is calculated so as to let pass only the ultra-penetrating rays. The lead screens, for instance, are superposed on apparatus with radium fixed in varnish containing 6 mg. to 1 cg. of sulphite of radium of A. 500,000, or else over glass ampoules containing pure radium bromide. The thickness of the lead sheath varies from five-tenths to several millimetres, to which are then added sheets of paper to a thickness of 1 or 2 millimetres. This is then put into a rubber sheath. The paper stops the secondary radiation given off by the leaden sheath, and the rubber protects the apparatus from the action of organic liquids.

Applications.—The apparatus of Dominici are either placed on the surface of tumours or in their depressions, or introduced by surgical operation into the interior of neoplasms. The apparatus is left in position for a period of 20 to 120 hours at the most for a single series of applications. The application is continuous or intermittent; thus, if a patient objects to wearing the apparatus during the day, it is left *in situ* from 9 p.m. to 9 a.m.; the apparatus is removed once or twice a day to be cleansed and to allow of the surface of the neoplasm being cleansed. In some cases the tumours receive at once the amount of radiation necessary to determine their retrogression; in other cases the treatment is recommended after an interval of three or four weeks. If the retrogression stops the treatment is begun again, and, if necessary, the intensity of the radiation and the length of its application are increased.

Therapeutic Effects.—Under the influence of the treatment the deep neuralgic pains cease, gangrene disappears, the neoplastic process stops, and finally, after a period of eight to fifteen days, during which a more or less intense flow of plasma occurs, the tumour begins to retrogress. The vegetations are reabsorbed, the ulcerations gradually fill up, the healthy portions of tissue become free, and, finally cicatrization is established in five to eight weeks. This applies to medium cancers, and not to extensive or very ulcerated or infiltrating cancer. Sometimes cancers of the skin require three or four months' treatment. It is simpler to treat cancers of medium type by the method of composite radiation producing a slough, an application of six to ten hours only being necessary; but when the tumours are extensive or deeply infiltrated and ulcerated, then the ultra-penetrating radiation is preferable. The latter is absolutely necessary in all cancers in cutaneous regions or those on mucous membranes only.

Treatment of Cancers of Cutaneous-Mucous Regions.—Wickham and Degrais have been able to cure cancers of the palpebral conjunctiva by short and repeated applications of apparatus of A. 500,000. Epithelioma of the mucous portion of the lip are aggravated by radiations of strong intensity. On the other hand, they are improved or cured by ultra-penetrating radiation, the intensity of which is relatively very small. Professor Gaucher described the three following cases:

1. Superficial epithelioma of the mucous membrane of the lower lip, of four years' duration, refractory to cauterizations with silver nitrate and the thermo-cautery. This was cured after twenty-four hours' application of an apparatus furnishing an ultra-penetrating radiation of about 3,500 gamma rays through 1 mm. of lead.
2. Typical cancrroid developed on the posterior surface of the lower lip in a plaque of leucoplasmia, in the form of hardened ulceration covered with a crust with raised edges, above the mucous membrane. Cured in two months after forty-eight hours' application of an apparatus giving 4,500 gamma rays through 2 mm. of lead.
3. Epithelioma of rapid development on the mucous membrane and at the left commissures of the lower lip. Cured after 40 hours' application of an apparatus giving a radiation of 4,500 gamma rays through $\frac{1}{2}$ mm. of lead. The cure is maintained—nine months since treatment.

The same treatment has been applied to cancers of the tongue, and Professor Gaucher has seen papillary epitheliomas restricted to the chorion of the mucous membrane retrogress after twenty-four or forty-eight hours' treatment with apparatus giving an ultra-penetrating radiation of A. 500,000. The "precancerous" condition of the mucous membrane—that is, leucoplasmia of the mouth—is

cured by this treatment. The results of treatment of infiltrating cancer of the tongue extending below the mucous membrane are encouraging, for amelioration has been obtained in conditions such that it would not seem impossible to cure eventually by means of radium certain varieties of one of the most terrible and the most incurable cancers.

The President of the Republic has conferred the Cross of the Legion of Honour on M. Louis Bazy, interne in the Paris Hospital, for the following act of devotion: In the month of March last, Dr. Iselin, chef de clinique of Professor Berger, was performing an Estlander's operation in the Necker Hospital, when Bazy, who was assisting him, received a spurt of pus in the left eye. He could not leave the operation as no one was washed and ready to take his place immediately. It was only when the operation was finished that he was able to take any precautionary measures, but the eye was already inoculated, and in a few days he had a conjunctivitis. At length, after seven months' suffering, it was necessary to enucleate the eye as sympathetic trouble was threatening the sound eye. Thirty years ago, in 1879, the Cross was conferred on M. Harbelin, interne in the Trousseau Hospital, who contracted diphtheria during a tracheotomy, but he died a few hours after receiving it.

MUNICH.

The Aerztliche Verein.—The Aerztliche Bezirks-Verein.—Other Medical Societies.—Post-graduate Courses.—The Library of the Aerztliche Verein.

Just seventy years ago twenty Munich doctors united to found the society known as the Aerztliche Verein. The object of the society was the furtherance of medical science, the exchange of practical experience, and friendly intercourse between the members. The sympathy it met with amongst general practitioners was not very great, as may be gathered from a letter addressed to the president by a doctor who had been asked to join the society. He wrote: "I cannot see how any advantage can arise from such a society, and I have no wish whatever to hear everybody theorizing in his own particular way. It is impossible that anything can be expected except general rivalry and difference of opinions. It is wiser that each man should draw his own conclusions and find his examples with the old masters according to his own ideas." What would the poor man have said had he lived nowadays, when every one is supposed to belong to at least half a dozen societies? Anyhow, he gave an entirely wrong prognosis, as appears from the fact that in 1836 the Aerztliche Verein organized the fight against cholera. Policlinic stations were established in all parts of the town, and members of the society gave their time and strength to the work. Later on their fight was renewed against typhoid fever, at that time a widely-spread, never-ceasing epidemic in Munich. It was also at the meetings of this Verein that Pettenkofer first developed his theories regarding the causes of these epidemics. These theories, little as they are recognized now, laid the foundation for the present hygienic sanitation of Munich and many another town. The Aerztliche Verein, which had been increasing steadily until it had become an important factor in public life, supported the views of its renowned member, and on this account received on the occasion of its fiftieth anniversary official recognition from the Government and the town council. From this time on the Verein became the centre of medical scientific life in Munich. It is even at the present date the most prominent medical society, though it has long ceased to be the only one.

There are, indeed, quite a number of medical societies. Medico-legal and ethical, as well as of late the economic, questions are dealt with by the Aerztliche Bezirks Verein, to which every qualified medical man must be admitted. It is in this Verein that the members for the Aerztekammern are elected. This Aerztekammer is the representative body, meeting once a year to consult the wishes of medical men concerning their own legal affairs and on questions of social hygiene. The Government is obliged at least to answer any requests made by the Bezirks Verein. This, of course, is not much if the Government

displays no goodwill or is not particularly interested. Yet it is something.

Beside these two Vereins there is the Neue Standesverein Münchener Aerzte, due to a secession from the Bezirks Verein, where a rule of tyranny had sprung up, the majority having got into the hands of a too radical element which treated social medical problems much in way of the social democratic organizations. Another Bezirks Verein for the districts around Munich includes also a number of Munich doctors amongst its members.

All these different Standes-Vereine, which deal with medico-legal affairs, are members of the Deutsche Aerzte Vereinsbund, the representative body of German doctors, which however is not based on an organization instituted and approved by the Government, as the Aerztekammern, but is a free union or combination. Further, all doctors who wish to treat Krankenkassen patients are required to enter the society for "Freie Arztwahl."

Scientific life has also been divided into several channels. There are ophthalmological, laryngological, pediatric, gynaecological, psychological, morphological, physiological societies.

There is besides these a Klinkerschaft uniting the students of medicine during the clinical years. This is intended to prepare these future doctors for the legal and ethical side of their later life. There is also a branch of the Leipziger Wirtschaftliche Verband, and there are some smaller clubs with the same object as the Aerztlicher Verein: in fact, there are now a-days so many specialities in medical societies that it is hard to say why the Aerztliche Verein still exists, especially as of late the scientific demands of practitioners have been met in the most admirable and satisfactory manner imaginable, and in a way that no papers read on scattered subjects in an evening could possibly fulfil. These are the "Fortbildungskurse" (post-graduate courses, lectures, etc.) held in the different clinical institutes and delivered by our best professors, docents, and practitioners, and accessible to every doctor free of charge.

But notwithstanding all this the Aerztliche Verein still holds the first place, and every doctor of repute will enter it. Perhaps not the least attraction presented by this society is its splendid library. Owing to the generosity of the editor of the *Münchener medizinische Wochenschrift*, Hofrat Spatz, this library is provided not only with all the important periodicals, both German and foreign, but through him and occasional donations from others adds yearly many volumes to its collection of books. When one sees the queer old building, standing in a quiet side street, resembling an old monastery, the broad stairs leading to the old-fashioned, dark, and mouldy rooms, the feeling strikes one of the disparity between it and its valuable contents. But in the meantime we must be satisfied with what we have until the longed-for Pettenkofer-Haus is built, where all the different scientific societies intend to have their club rooms. Whether, however, this will ever be built, and, if so, when, nobody knows.

According to the *Deutsche medizinische Wochenschrift*, the total number of medical practitioners in Germany on November 1st, 1908, was 31,640, as against 31,416 on the corresponding date in the previous year. They were distributed among the various States as follows: Prussia, 19,130; Bavaria, 3,487; Saxony, 2,298; Württemberg, 1,043; Baden, 1,263; Hesse, 747; Mecklenburg-Schwern and Mecklenburg-Strelitz, 362; Oldenburg, 165; Brunswick, 265; Thüringen, 706; Anhalt, 150; Waldeck, 50; Lippe and Schaumburg-Lippe, 77; Lübeck, 77; Bremen, 198; Hamburg, 721; Alsace-Lorraine, 903. The proportion of doctors to population in the large cities was as follows, the ratios given being per 10,000 inhabitants: Wiesbaden, 25.8; Munich, 15.8; Strassburg, 14.2; Kiel, 13.1; Larger Berlin, 12.3; Frankfurt-on-the-Main, 12.1; Halle, 11.8; Karlsruhe, 11.7; Breslau, 11.6; Königsberg, 11.2; Posen, 11.1; Hanover, 10.9; Cassel, 9.8; Dresden, 9.8; Cologne, 9.7; Stuttgart, 9.6; Leipzig, 9.4; Stettin, 8.7; Danzig, 8.7; Brunswick, 8.5; Düsseldorf, 8.4; Aix la Chapelle, 8.3; Magdeburg, 8.2; Hamburg, 7.8; Erfurt, 7.5; Nuremberg, 7.5; Bremen, 7.1; Mannheim, 7.0; Altona, 6.1; Dortmund, 6.0; Krefeld, 5.7; and Elberfeld, 5.7. Included in the list are 55 women doctors, who practise almost without exception in the towns. Berlin has 17; Breslau, 5; Frankfurt-on-the-Main, 4; Munich, 3; while Hamburg and Dresden each have 2.

Correspondence.

LORD LISTER ON SULPHO-CHROMIC CATGUT.

SIR,—I desire with your permission to add in your columns a few words regarding sulpho chromic catgut to what was stated in my paper on the preparation of catgut for surgical purposes published in the *JOURNAL* on January 18th, 1908, p. 125. It does not begin to be absorbed for about ten days, and it is then gradually eroded, retaining considerable firmness to the last. It is thus well adapted not only for tying vessels in wounds, but also for the ligature of arterial trunks in their continuity and for buried sutures. Its trustworthiness for these purposes has been amply demonstrated by long experience.

I may add that immersion of the catgut in 1 to 20 solution of carboic acid for about twenty minutes before the commencement of an operation has afforded perfect security of an aseptic state of the thread, while no disadvantage arises from its remaining in that solution for any length of time which on other grounds may be found convenient.—I am, etc.,

January 14th.

LISTER.

THE DEPARTMENTAL COMMITTEE ON THE MIDWIVES ACT AND GENERAL PRACTITIONERS' INTERESTS.

SIR,—The appointment of a Departmental Committee to inquire into the administration of the Midwives Act, 1902, is an incident of considerable importance to a large portion of the medical profession in England and Wales, especially to the general practitioners whose work lies entirely or partially among working-class communities, yet the event appears to have attracted very little attention from those whose interests are chiefly involved. With the exception of an excellent account of the local situation and the state of professional opinion given by your Manchester and Salford correspondent (January 16th), there has been no reference to the subject in the *BRITISH MEDICAL JOURNAL* as far as I have noticed.

The Departmental Committee appointed by the Lord President of the Council will be chiefly concerned with two questions: (1) As to the supply of midwives; (2) as to the remuneration of medical practitioners called to abnormal cases by midwives acting under the rules of the Central Midwives Board.

As a member of the Central Midwives Board nominated by the Lord President it would be unbecoming in me to criticize the composition of his Lordship's Departmental Committee, but I have no desire and I am under no temptation to do so. Any serious inquiry must be useful. There is, however, one defect so obvious as to suggest mere oversight, yet probably entailing such unfortunate consequences that it may be mentioned with the wish to be helpful, and without offence to any concerned. The Departmental Committee as at present constituted contains no member of the medical profession conversant with the routine of midwifery work among the poorer classes, with the sort of practice, in fact, which brings the doctor into close relations with the midwife while she is engaged on the duties of her calling. The Departmental Committee is, without doubt, composed of able men, all distinguished in their own particular official positions, but it is difficult to believe that the report of a committee even so composed will be received with the same confidence by the medical profession as that of a committee containing one or more medical members qualified by special experience, independence, and sound judgement to elicit the most valuable evidence, not merely to give evidence.

It would be a misfortune if an easily removable defect were to weaken the confidence of the great body of the medical profession in the value of the report of the Departmental Committee when it appears, and diminish the ardour of co-operation in giving practical effect to recommendations.

With regard to the two chief points for inquiry, I should like to offer some suggestions to our professional brethren. These suggestions are the outcome of considerable rumination over the reports which come regularly to the Central Midwives Board, and over what one learns in conversations with medical practitioners, weighed in the light of

personal experience as a general practitioner in years gone by. My suggestions, put forward with all diffidence, may form some basis of discussion among those chiefly concerned. I harbour no illusion that they are matured in detail for practical application.

First, with regard to the supply of midwives, we are at present, both as to quantity and quality, just emerging from a state of barbarism. There are too many midwives of sorts here in the North; it is alleged that there are too few in the South and West of England. That may be true; but there are over 15,000 midwives actually in practice in England, with an annual increment of about 1,000. Any distribution by relieving the congested districts is of course utterly impracticable. As a rule, the ordinary midwife, except she occupies an official position, must practise where she was brought up, or at least where she has resided for years and is well known. With the officially appointed it is different. Another difficulty to be overcome or circumvented is that so few of the numerous midwives can make a decent living out of their professional earnings alone. And now that quackery among women and infants has been suppressed by the tyranny of the Central Midwives Board, the struggle is harder than ever. Many of them have to engage in supplementary occupations not always compatible with the midwife's calling. Upon the whole a distinct improvement is already observable among the midwives as a class. There are, of course, many shocking exceptions, but these are being gradually eliminated through the administration of the Midwives Act by the local supervising authorities and by the Central Midwives Board. How, then, are we to maintain a reasonable standard of efficiency while supplying a sufficient number of midwives for the classes of the population of England and Wales which require their services? A suggestion for a solution comes from the recent action of some of the county councils. Several county councils in England have offered scholarships or bounties to suitable women to induce and enable them to go into training as midwives. If this is done voluntarily by some local authorities, why should it not be made obligatory on all? That is to say, the State, as in Continental Europe, should train and partially subsidize the number of midwives required by their people. In this country "the State" would be the county and county borough councils, and they would select suitable pupils for training and train only the number required in their own areas. This arrangement would do away with the demoralizing competition which there is some reason to fear is already tempting to crime. It would also put an end to that selection of the unfittest which we may observe now going on all over England. It is such economical and easy benevolence to dispose of the widow of a manservant, or support the poor woman burdened with a chronically ailing husband, to send her for training as a midwife. The ground of selection is not the fitness, but the poverty of the pupil. Under a better system, if such women were not only poor, but fitted by education and temperament to make efficient midwives, so much better satisfied with the selection the committee of a county council might be—conscious of a public service and a benevolent action. But it is a mere platitude to assert that poverty alone should never establish a claim to public assistance towards training for the calling of midwife. There are many arguments in support of the changes which I am hinting at. The better the position of the midwife, the more it will be sought by the most suitable class of women, and the more the midwife will fear to lose her post by transgressing against either moral or legal obligations in her professional capacity. It might be premature to suggest here the establishment by co-operation of rate-aided lying-in hospitals for the training of midwives like the State-supported maternity hospital schools of France and Germany and other countries; these will come with the municipalization of all public hospitals and the restriction within reasonable limits of "hospital abuse," a consummation perhaps not so far off as the many who are indifferent to the signs of the times may believe.

The second important question before the Departmental Committee is the remuneration of medical practitioners who are summoned at the request of midwives to render assistance in cases of danger or difficulty. The worst blot upon that very defective measure, the Midwives Act, 1902, is the entire absence of any germ of a provision for the

payment of fees to medical practitioners called upon to render their professional services to poor women in emergencies. Probably the advocates of the Bill felt in their haste to get it through that if it were weighted with controversial clauses it would sink out of sight. Nevertheless the Act with some amendments appears destined to work a beneficent social revolution. The most urgent amendment required is the removal of the intolerable grievance from which the hardest working members of the medical profession suffer at present.

It is therefore highly desirable that suitable witnesses should go before the Departmental Committee to offer evidence founded on intimate personal knowledge of the working of the Midwives Act as it affects the general practitioner.

It seems to me that sympathetic and well-informed witnesses from the Manchester and Salford area alone could contribute most important, perhaps sufficient, evidence on the working of the Act in urban communities. Manchester shows the administration of the Act at its best; Salford at its worst. There can be few districts in the country where such a striking and instructive contrast forces itself upon public attention. In Salford an unenlightened majority of a borough council refuses to administer the Act in an efficient manner, and subjects the medical practitioners within its jurisdiction to ill-usage, while an unspeakable board of guardians endeavours to increase the number of paupers among its working people and withholds on paltry pretences well-earned remuneration from the practitioners who are so unfortunate as to be called upon to do the work in emergencies of their district medical officers when they cannot be found. In Manchester everything is in favourable contrast to this: details would occupy too much space, but the facts are open to all the country. There is no need for concealment. I should like to add that Manchester is unique in the country in making admirable provision for poor women suffering from any form of puerperal fever instead of sending them to the workhouse.

I have no idea what the scope of the evidence which the Departmental Committee will require may be, but some account of the administration of the Midwives Act in Manchester and Salford could hardly fail to be relevant and useful, and our local medical organizations might very well combine in the endeavour to get the facts of the local situation brought to the attention of the Departmental Committee.

The most important question of all which keeps forcing itself upon our minds is this: What must be the amendment of the Act which will remove the exasperating grievance under which so many practitioners suffer? They give their services night or day well knowing that there will be no payment, or they refuse to obey the summons, and are held up to the scorn and contempt of their neighbours as hard-hearted, callous, cruel, and avaricious.

Such a condition of things is intolerable; it has been suffered too long, and should cease forthwith.

This is no political question, and the whole profession might combine to use such influence as it may possibly possess in order to obtain a reasonable settlement. Local authorities should be made legally responsible for the fees of the accoucheurs who come to the aid of the midwives in emergencies. The employment of a midwife under existing social conditions may well be considered *prima facie* evidence of poverty in the family of the patient, and if any proportion of professional fees is recoverable from husbands, that must be a question for the local supervising committee, not for the doctor. He should be as confident of receiving payment for this kind of work done as he is at present of receiving a fee for the notification of certain diseases. It is all work in the interests of organized society. Prompt and skilful treatment in cases of obstetric emergency saves lives, and prevents the disablement and misery which results from certain chronic ailments. Such aid brought to the poorer working-class women has the additional advantage of saving the pockets of the ratepayers by preventing extreme impoverishment and consequent demand for relief from the rates. To the ratepayer it matters little whether the pittance which goes into the professional purse is administered by the city, or borough, or county council, or by the board of guardians, but, as a rule, he has "no use" for the

guardians; he only wishes to know that his money is disbursed fairly and for value received without the harassment and ill-usage of those who have earned it.

If you work out the arithmetic of the situation by addition and subtraction, without attempting to estimate pain and agony of mind, you will come to the conclusion that it would well repay the ratepayers of city or county to take matters out of the hands of the "guardians of the poor," to put a stop to the cruel ill-usage of the humble medical practitioner, and to remunerate him decently well for his services to the community.—I am, etc.,

Manchester, Jan. 18th.

WILLIAM J. SINCLAIR.

* Sir William Sinclair has probably overlooked references to the appointment of the committee published in the JOURNAL during December. During the last year the whole subject of the payment of medical practitioners called in by midwives has been frequently discussed in the Association and mentioned in the JOURNAL. The discussion on the subject at the Annual Representative Meeting was reported in the SUPPLEMENT to the JOURNAL of August 1st, p. 137 et seq. A motion made at that meeting was finally adopted in the following amended form:

That it is the opinion of the Representative Body of the British Medical Association that no arrangements for obtaining the skilled assistance of the medical profession for midwives in an emergency or otherwise will prove satisfactory until, in the interests of humanity, it is made compulsory on the Local Supervising Authorities to guarantee payments to all members of the profession for such assistance on a definite scale of fees.

The Medico-Political Committee of the British Medical Association, at its meeting on January 6th, 1909, resolved to recommend the Council to authorize it to prepare and submit evidence on behalf of the Association to the Departmental Committee, in accordance with the previous decisions of the Association on the subject. This recommendation will come before the Council at its meeting on Wednesday next. It may be convenient to add that the Departmental Committee is constituted as follows: Mr. Almeric Fitzroy (Clerk to the Privy Council), Chairman; Mrs. Charles Hobhouse, Mr. J. S. Davey, C.B. (Assistant Secretary, Local Government Board), Dr. A. H. Downes (Medical Inspector for Poor-law Purposes, Local Government Board), Dr. F. H. Champneys (Chairman of the Central Midwives Board), Mr. John Pedder (a Principal Clerk, Home Office). A preliminary meeting to arrange the course of procedure was held on December 16th, 1908, and Dr. Francis E. Fremantle (M.O.H. Hertfordshire, and a Member of the Council of the Association for Promoting the Training and Supply of Midwives) was added to the Committee shortly afterwards. The Committee held its first meeting for the hearing of evidence on Wednesday last, January 20th, when Mr. G. W. Duncan, Secretary of the Central Midwives Board, gave evidence on its behalf. As already stated, the President of the Midwives' Institute protested, immediately after the composition of the Committee was announced, against the omission of a representative of the midwives. We are informed that Miss Wilson has now resigned her seat on the Central Midwives Board by way of emphasizing her protest. We understand further that Mr. Parker Young had the following notice of motion on the agenda paper of the meeting of the Central Midwives Board on Thursday, January 21st:

That the Lord President of the Council be respectfully requested to consider the advisability of adding to the Departmental Committee representatives of the interests of general medical practitioners and midwives, as the Board consider that such additions would greatly enhance the value of the report eventually come to by that committee.

THE STATE REGISTRATION OF NURSES.

SIR,—My letter in the JOURNAL for December 12th, 1908, has called forth so many critics that considerations of space compel my reply to each to be of the briefest. I have to thank Mrs. Hadfield and Miss Mollet for the courteous tones of their communications. The former lady's query as to why the matrons and nurses opposed to registration do not hold meetings in protest is a fair and reasonable one. It is much more difficult, it may be said, to arouse enthusiasm in those who are merely resisting than in those who are clamouring and contesting for a change in the existing order of things. When the proposed change involves a manifest injustice to themselves, those concerned are apt to rest in a state of fancied security that

it will never be allowed to be brought about. The matrons and nurses opposed to registration, moreover, are mostly engaged in the active practice of their profession, and it is difficult to arrange and organize meetings amongst ladies whose time is so fully occupied. A better proof than that afforded by many meetings of the nurses' objection to registration is that only lately they have been extensively circularized and urgently implored to join the promoting society, and their response to the appeal has been but feeble. They might deplore the "present chaotic state of nursing affairs" and "wring their hands," but still they have not joined in any considerable numbers.

Mrs. Hadfield does not strengthen her case by her reference to the London Hospital. Like only too many others, she attempts to narrow the point at issue into one of a difference between the nursing arrangements at that hospital and those obtaining elsewhere. But the question of registration is a vastly wider one, concerning the nurses at numberless other hospitals besides the London. As that hospital is so often attacked, however, it is only just to say that, with ample opportunities of judging, I am perfectly satisfied that the nurses sent out by it are in every way capable and efficient.

Miss Mollett's letter is more ably written than convincing. The objection to registration arising from the dread of creating a body of inferior medical practitioners is to me a minor one, and yet one deserving of some attention. My main objections to registration Miss Mollett only meets with vague promises of what will be accomplished by the "Nursing Council" when once registration is established. With a recollection of the conduct of her two societies in the past, and the large share they are clamouring for in the representation of that "council," I would still cry to my fellow-practitioners, "Ne credite ego." There is no vagueness about one portion of Miss Mollett's letter; on the contrary, there is a clear indication of how her two societies, if they gain their way, are prepared to interfere and dictate in the nursing arrangements of every hospital in the kingdom.

With Drs. Shuttleworth and Hayes Newington I am in cordial agreement. The injustice, absurdity, and insuperable difficulties attaching to any scheme of general registration do not apply to a separate one for their nurses, male and female, with their more strictly special and uniform training. Should such a form of registration, too, be established, it would be only right that gentlemen with experiences similar to their own should have a dominant voice in its control and management.

My contention that a majority of the medical profession are opposed to registration has not been challenged in the JOURNAL, although it has been elsewhere. That being so, I will only say at present that I am prepared to substantiate it, and that at the time it was penned I was fully aware that 90 out of 93 members voted in favour of it at an annual meeting of the Association.

Mrs. Bedford Fenwick says I argue "as if there were but twelve hospitals in London," but I fancy she will be the only person to take me in that light. So much had been claimed for the Matrons' Council and the Society for the State Registration of Nurses, that they were "representative of all that is best in the nursing world," that it was essential to point out, regarding the former body, that, whilst they could only claim the matrons of three of the twelve leading hospitals in London as belonging to it, the matrons of the rest were opposed to registration. A similar disproportion, in the same direction, obtains in the case of the matrons of the leading hospitals in the provinces and Scotland. To point out these facts is not to ignore the numerous other hospitals and the excellent work done at them by matrons and nurses. Mrs. Fenwick apparently is more enamoured of the work of the matrons and nurses at most hospitals than these ladies are impressed in favour of her societies. Let me call her attention, and that of Miss Mollett, to a report of a meeting held in Edinburgh, in the JOURNAL for December 19th last. The meeting was rightly claimed as being "highly representative" of both the nursing and medical professions in Scotland, and it was unanimously agreed to take steps to oppose the present bill. One speaker, moreover, called attention to the significant fact that at a meeting which was, without doubt, thoroughly representative of the nursing profession in Scotland, not a single member of the Matrons' Council was present.

Mrs. Fenwick charges me with inaccuracy, but the charge sits lightly on me. It matters little whether the Society for State Registration was only nominally formed in 1902, when the coterie responsible for calling it into being, and for its title, is identical with that which has been endeavouring for twenty years and more to gain control of the nursing profession. It is unreasonable to expect the ordinary individual to follow her societies in their flights at nomenclature, of which the "Matrons' Council of Great Britain and Ireland" is such a masterpiece. In a nursing publication largely devoted to the interests of her societies I read of numerous other societies with high titles, all in favour of registration, and a high authority in the nursing world has, not inaptly, compared them to "stage armies."

Mrs. Fenwick is certainly "courageous in raising the bogus cry of "coercion" in a medical journal. Such a charge might influence the layman, but will certainly not serve with any one with the slightest acquaintance with hospital régime. I certainly know of no hospital committee which would seek in any way to influence, let alone coerce, their nurses either for or against registration. If Mrs. Fenwick is better informed, let her give specific instances, instead of dealing with generalities without forthcoming proofs. Moreover, if hospital authorities take such unworthy advantage of their positions, which is unthinkable, what is there to prevent the trained nurses from joining her societies when they have passed from under the committees' control?

The rest of Mrs. Fenwick's letter simply obscures and is beside the question. She knows, or ought to know, that the present bill does not even pretend to abolish the evils in the nursing world to which she refers. On the contrary, it would, in my opinion, tend to further and increase them.

Lastly, there is evidence that in the Colonies registration has resulted in a lowering of the social status and education of those entering the nursing profession, and has led to a diminution of the standard of training. It is further stated that one at least of the legislative bodies has been approached with a view to the course of training being reduced from a three years' to one of two years' duration. —I am, etc.,

London, W., Jan. 19th.

J. A. COUTTS.

THE DRAFT CHARTER AND THE REFERENDUM.

SIR.—At the last Representative Meeting I voted for the Cardiff resolution in favour of a Referendum by voting papers sent to every member. I did so solely for the sake of conciliation, though I have always felt that on many subjects no member can possibly be in a position for forming a good opinion unless he attends Division meetings. But recent events have made me doubt whether my vote was well placed. To my mind, Mr. Ballance was only doing his duty as Deputy Chairman of the Representative Meeting when he uttered his protest in the JOURNAL of January 9th. Moreover, it has become evident that if a voting paper Referendum is ever to be satisfactory, some steps will have to be taken to ensure that both sides of any question are fully presented to the voters. To present only half a case cannot be a good way of arriving at the best opinion of the Association.

On considering the various matters that are ever likely to be the subject of a Referendum, it would seem possible to divide them into two great classes: First, the additional objects for which the Charter was largely framed, which are named in Section 2 (2), vi, vii, viii, ix of the Charter. They are, in brief, the supporting of Parliamentary candidates, facilities for sales of practices, and schemes for medical defence and benevolence. On such broad subjects I imagine every member is competent to form a good opinion without attending a Division meeting. Even the so-called "JOURNAL members," who either take no interest in medico-politics, or at any rate whether from choice or inability never attend a Division meeting, can form a proper opinion on such matters from their own personal knowledge. I would suggest, then, that on these matters, and only on these, Referendum by voting papers might be allowed. This would go a long way towards satisfying those members who fear lest the Representative Meeting may launch out too fast into new enterprises.

On the other hand, there are many subjects where no one can be expected to give a proper opinion unless he

attends a meeting where difficulties can be ventilated and both sides of the question be fully debated and explained by experts. Full discussion on such subjects as the medical treatment of school children is essential before any one can possibly be in a position to give a satisfactory vote. On such matters, then, I would recommend Referendum by personal voting in Division meetings, at which, of course, every member has a right to be present.

Now it must be evident that neither the Council nor the Representative Meeting will agree to any further postponement of the application for the Charter. It is too late to draw back, and whatever happens the Charter must go forward as it is. But there is no reason why there should not be some present concordat as to some future modification of Ordinance 17 which can easily be effected after the Charter is obtained. It is humiliating to have to confess that the greatest stumbling-block in the way of such a concordat is the feeling of mutual suspicion that exists, and any proposal from either side must attempt to allay these suspicions. Compromise of some sort must be attempted. It may be true, according to the opinion of legal counsel published last week, that the opposition of the South Western Branch cannot be maintained before the Privy Council, but we ought not to be satisfied with that. We should not be content with simply squashing opposition: we want union, and it is not sufficient to gain a victory by driving discontent below the surface.

I would propose, then, that those Branches which have threatened to oppose the Charter should be approached, not from any fear of their opposition being effective, but in a true spirit of conciliation, and that an amendment of Ordinance 17 on something like the lines above suggested be proposed. This could hardly be done officially, as the Council is now bound to prosecute the request for the Charter as it stands. Of course, there is no guarantee that the Representative Meeting would ratify such a proposal when the Charter is once obtained, though I am strongly of opinion that it would be accepted provided the present opposition be dropped. If my confidence in this is not shared by the South-Western Branch I would further suggest that, without calling together a Special Representative Meeting, all the present Representatives might be circularized, and asked if they would agree to such a compromise after the Charter is obtained. Even that, of course, would not bind a future Representative Meeting, but it would go as far towards it as is possible, and to ask for more is to ask for what is constitutionally impossible.

If I understand the feelings of the members of the South-Western Branch they do not so much desire to throw out the Charter as to have a particular alteration made beforehand. The method they threaten to take to obtain this cannot possibly succeed. The worst they can do is to delay the Charter; even that is hardly possible unless counsel's opinion is utterly wrong. The next worst is that they may cause a great waste of Association money. I am sure they can find no satisfaction in that. All the Privy Council can do is to reject the Charter. And what then? Will the South-Western Branch be any nearer to getting a voting paper Referendum? Not in the least. Rather I imagine the feeling of irritation that would be caused would indefinitely remove any such possibility, and might even prevent any proposal for compromise being accepted. These are not threats: they are simply a presentation of human nature as it is. In fact, the South-Western Branch has everything to lose and nothing to gain by catching at too much. The scheme I have ventured to propose may seem impractical and chimerical if an absolute guarantee is demanded. It is, at any rate, an attempt to go as far towards compromise as devotion to the best interests of the Association will allow me. I give every credit for a similar feeling to the South-Western Branch, and I am not without hope that both sides to this dispute will see that there is more to be gained by conciliation than by force and mutual recriminations.—I am, etc.,

Salford, Jan. 18th.

J. H. TAYLOR.

SIR,—In your issue of January 16th Mr. Lynn Thomas complains of "the precipitancy with which action has been taken in the matter of the Charter by a few officials and others in the name of the Association."

The facts are as follows: At its meeting on October 28th, 1903, the Central Council approved of the draft Charter,

Ordinances, By-laws, and Schedule thereto, submitted by the Organization Committee as finally revised by Counsel, and of the form of petition to the Privy Council praying for the grant of such Charter: it also passed a resolution directing that all necessary steps be forthwith taken to present a petition to His Majesty to grant a Charter in the form approved; and it further referred the matter to the Chairman of Council and the Chairman of the Organization Committee to carry out the necessary arrangements. The petition was presented on December 21st.

Mr. Lynn Thomas appears to think that these two officials should not have acted on the very explicit instructions, duly given to them by the Council at its meeting on October 28th, 1903, at which Mr. Lynn Thomas was present, to arrange forthwith for the presentation of the petition.

It will be for the Council at its next meeting to approve or to disapprove of the action of these two officials as it may see fit, and I as greatly regret the attitude adopted by Mr. Lynn Thomas as I do the tone of his letter.—I am, etc.,

Norwich, Jan. 19th.

H. A. BALLANCE.

SIR,—Did the postcards, showered without warning upon the members of the South-Western Division, really prove anything by the almost unanimous replies? I was talking to a member quite recently, who said that he replied in the affirmative on his card; but, as a matter of fact, he knew nothing about this Referendum business.

Such replies to a question (which, by the way, appeared to require an affirmative answer), sprung upon busy men who probably have never given the subject a thought, or considered the disastrous consequences which such a vote means after the Charter is cut and dried for passing, I believe to be unreliable. Insurrections spread among the masses like wildfire, and here we have issuing as a result a general upheaval which is calculated to wreck the long-looked-for Charter. The armchair critic is a useful individual, but the armchair voter, with his feet on the mantelpiece, is often indifferent in matters requiring thought and attention.—I am, etc.,

Liskeard, Jan. 19th.

JOS. WM. GILL.

SIR,—It is very kind of Dr. McKenzie Johnston to speak of certain extracts from a letter of mine published in the *JOURNAL* of November 2nd, 1907, as "excellent" and "wise quotations," and I appreciate the compliment. But I deny the charge of inconsistency which would seem to be conveyed by the quotations in question. I am now, and have always been, in favour of what is contended for by the opponents of the present Charter, but none the less I repudiate *in toto* the unconstitutional method adopted to enforce their views.

Dr. Johnston will observe that my "very strained construction" has been adopted by eminent legal authority, and would appear to be the law. I should have thought that to the "ordinary mind" the clause I quoted meant what it said, and that if a council were to be appointed to manage only the affairs of a Branch, it was not intended to arrogate to itself the right of performing functions reserved by the Articles and By-laws for the executive of the whole Association. If the views of a Branch have been properly brought before that executive by its appointed delegates, and rejected after due consideration in a proper and constitutional manner, is it right for that Branch to hamper the Executive when acting for the whole Association? Is it playing the game? I think not, and although I am in favour of the postal vote and opposed to the two-thirds majority of Council *re* Referenda, in my opinion these matters are insignificant in comparison with the unconstitutional course taken by those whom I should otherwise be prepared to support. The want of cohesion and self-discipline, which is only too evident in many of the letters published in the *JOURNAL* on this subject, is much to be deplored, and does not augur well for the future of the Association. It seems only too likely that the Privy Council, when it perceives how little respect has been shown for our present Articles of Association, will hesitate to grant us any Charter when the whole matter comes under its consideration.—I am, etc.,

London, N.E., Jan. 19th.

MAJOR GREENWOOD.

SIR.—At a meeting of Eastbourne Division, held in the Mayor's Parlour, Town Hall, Eastbourne, on the 15th inst., the following resolutions were unanimously adopted, twelve members being present:

1. That this meeting of the Eastbourne Division of the British Medical Association, taking into consideration the fact that the proposed system of taking the Referendum was before the Divisions for weeks before the Annual Representative Meeting at Sheffield, was passed at that meeting by a large majority, and subsequently confirmed by the Council, earnestly appeals to those Branches opposing the Charter to withdraw their opposition.
2. That the honorary secretary be instructed to forward a copy of the foregoing resolution to the Editor, for publication in next week's issue of the JOURNAL.

—I am, etc.,

Eastbourne, Jan. 16th.

WM. MUIR SMITH.

SIR,—By direction of the Council of the Southern Branch, the following question has been put to every member of the Branch:

Do you approve of the Branch Council joining the Council of the South-Western Branch in taking the necessary steps to lay before the Privy Council their view that a Referendum should be taken on the requisition of half the Council, and then by letter addressed to every member of the Association?

The replies received are:

Yes	173
No	10

The total membership is 419.—I am, etc.,

H. J. MANNING,

Salisbury, Jan. 16th.

Honorary Secretary.

OPERATIONS FOR CARCINOMA OF THE TONGUE.

SIR,—Will you allow me to refer to Mr. Butlin's article in the BRITISH MEDICAL JOURNAL dated January 2nd? Since writing my paper, which was published in the *Practitioner*, November, 1905, and which Mr. Butlin does me the honour to discuss, I have discovered another fact which increases the necessity for the removal of the entire hyoglossus muscle, even in small cancers which are situated on the dorsum of the tongue anywhere in the middle of its anterior two-thirds. In two cancers of this kind I have found in each case small cancer-bearing lymphatic glands buried among the fibres of the hyoglossus muscle, the fibres of which muscle had to be ruptured before the lymphatic glands could be presented. To me the interesting point about these lymphatic glands was their position. In consequence of their situation, they would have been unrecognizable and inaccessible in any operation conducted from the mouth. The only way in which they could have been safely removed was the method by which they were removed—that is, by excising the hyoglossus muscle from its attachment to the hyoid bone.

Mr. Butlin appears to me to agree with the main object of my paper, which was to attack a commonly adopted method of dealing with advanced but operable cases.

Increasing experience increases my difficulty in deciding which is the small cancer of the tongue; the size of the superficial ulcer or fissure, as the case may be, may be very misleading.—I am, etc.,

London, W., Jan. 18th.

G. LENTHAL CHEATLE.

APPENDICOSTOMY FOR INTUSSUSCEPTION AND FOR INTESTINAL OBSTRUCTION.

SIR,—That Mr. Carwardine should not think well of appendicostomy in cases of intussusception is natural under the circumstances he relates, but he can scarcely connect the death of his first case, "collapsed" when operated on, with the appendicostomy, and perhaps the recurrence in his second case was equally independent of that operation.

I should be glad, with your permission, to acknowledge that my very brief allusion to this subject in former papers requires qualification and justification. In the great majority of cases intussusception begins in the ilco-caecal region. In most dangerous or fatal examples the caecum is carried far away from its proper seat, and generally half round the abdomen into or near the left iliac region. Mr. Charles Clubbe, of Melbourne, whose personal experience of about 144 cases

in fourteen years entitles him to speak with great authority, says the most frequent starting point is the *caput caeci*.¹ In one of my cases the appendix was invaginated, its distal into its proximal part. That the appendix may play a part in starting the trouble may also be inferred from the fact that Meckel's diverticulum does sometimes start an intussusception. Naturally, therefore, the appendix has been removed as a prophylactic, by the late Herbert Allingham. An analogy with Mr. Carwardine's letter may be recognized in the report of von Prendisberger that he had seen the amputated appendix stump form the starting point of a new intussusception (J. V. Wichmann).

But when intussusception recurs after operative reduction, it is said generally to affect a different part of the intestine.² Therefore I should not expect appendicostomy to prevent recurrence altogether; but I should expect it to hinder recurrence, to limit its size, and to prevent the tumour from being carried right round the abdominal cavity into regions where the difficulty of manipulating it is increased.

It has been said with confidence that anchoring the caecum must favour intussusception by furnishing a fixed point. This would be true if the invagination were effected by some external force like that of the left hand putting a glove on the right. But intussusceptions are effected by internal force, by the circular and longitudinal muscle fibres of the intestinal wall. Fixing the caecum no more favours this than stopping a train would help a passenger to shut the sliding door of a compartment in a corridor carriage.

But there are other reasons for performing appendicostomy when operating for intussusception, besides the possibilities above mentioned. It permits immediate hot lavage of the intestine, which is inflamed and bruised, and its peritoneal coat often torn by the intussusception or by its operative reduction; it checks haemorrhage, and washes away clots and decomposing mucus and faeces. Its value as a means of recovering from shock may be disputed, on the ground that hot water, or neutral saline solution, or peptonized milk can be easily administered per rectum; but they are not in danger of being quite so quickly and completely returned when passed in through the appendix.

I should like to add that appendicostomy for this purpose can be done in the simplest possible way. The abdominal incision will most likely be near the outer border of the right rectus—that is, so placed that the appendix will come through it easily. One stout catgut suture through the caecum close to the appendix root and through the parietal peritoneum, and one silkworm-gut suture to attach the appendix to the skin, will suffice. The latter and the ligature which ties the appendix to the catheter need no prolongation of the anaesthesia whatever. With or without appendicostomy, the abdominal incision has to be closed. The appendix lies, as it were, in the surgeon's hand when he has reduced the intussusception.

Intussusceptions may be roughly classified into (1) ordinary or fairly mild cases; (2) severe cases—that is, such as can be reduced, though perhaps not without difficulty, leaving a segment of intestine a good deal bruised and inflamed; and (3) irreducible and desperate cases. Appendicostomy is for Class 1 and still more for Class 2. For Class 3, in which Mr. Carwardine's first case should be placed, may I suggest that the required first injection is not so much of milk into the colon as of neutral saline into the internal saphenous vein? But, of course, such cases generally die, whatever may be the details of treatment.

Mr. Carwardine has made a mistake of one year in the date of that case of intestinal obstruction of mine to which he refers, and though it was the first of my cases in which the faeces were for a time wholly evacuated through the appendix, it was not the first case of intestinal obstruction for which I did an appendicostomy. In the BRITISH MEDICAL JOURNAL, October 7th, 1905, p. 865, will be found this sentence: "Since this paper was read, Dr. Crombie of Sidcup and I have performed appendicostomy as a substitute for caecal colotomy, and have found the appendix easily dilatable." In the *Lancet*, 1906, April 14th, p. 1023, this case is referred to as having been

¹ BRITISH MEDICAL JOURNAL, 1907, Jan. 15th, p. 1428.
² J. V. Wichmann, of Copenhagen. *Nordiskt Medicinskt Arkiv*, 1905, Abt. 1, H. 3, N. R. 13. (The paper is in German.)

performed "partly" with the object of "giving egress to faeces." It was a genuine case of intestinal obstruction with faecal vomiting; but, as it proved to be wholly due to accumulation of faeces in a subject of chronic constipation, it was referred to as above, and in my last paper it is classed as a case of chronic constipation (Case 27). Every one of these case reports is an abstract of an abstract; and, though carefully made, details of some importance may be occasionally omitted accidentally. In this manner I have unintentionally misled Mr. Carwardine, and no doubt others. He is too powerful an ally in upholding appendicectomy for me to dispute with him about any question of priority. I congratulate him sincerely on the cases of appendicectomy for intestinal obstruction he mentions. They should deserve publication and prove instructive. Apologizing for the length of this, I am, etc.,

London, W., Jan. 19th.

C. B. KETLEY.

IS APPENDICITIS A MODERN DISEASE?

SIR,—The interest which appears to be aroused by the condition of King Herod's appendix, leads me to believe that the moment is opportune for reminding your readers that an excellent description of a case of appendicitis is to be found in Heister's *Observations*, and the following extract is from Wirgman's translation:

Observation CX.—In the month of November, 1711, as I was dissecting the body of a malefactor in the public theatre at Altdorff, I found the small guts very red and inflamed in several places, inasmuch that the small vessels were as beautifully filled with blood as if they had been injected with red wax, in the most skillful manner, after Ruysh's method. But when I was about to demonstrate the situation of the great guts, I found the Vermiform Process of the Caecum preternaturally black, adhering closer to the peritoneum than usual. As I now was about to separate it, by gently pulling it asunder, the membranes of this process broke, notwithstanding the body was quite fresh, and discharged two or three spoonfuls of matter.

This instance may stand as a proof of the possibility of inflammations arising, and abscesses forming, in the appendix, as well as in other parts of the body, which I have not observed to be much noticed by other writers; and when, in practice, we meet with a burning and pain where the part is situated we ought to give attention to it. It is probable that this person had some pain in this part, but of this I could get no information. In such cases I look on clysters prepared with emollient and discutient herbs, such as mallows, marsh-mallows and camomile-flowers, boiled with milk and used frequently to be of excellent use; as they reach the part and may resolve the inflammation, partly by their warmth, partly by their resolving and discutient qualities, opening the abscess, that the matter may be discharged by stool, and the patient hereby may be saved; which when the parts in the abdomen become corroded, can scarcely happen, but death must follow.

—I am, etc.,

Birmingham, Jan. 17th.

LEONARD G. J. MACKEY.

THE RHEUMATIC ORIGIN OF SEROUS INFLAMMATIONS.

SIR,—Without the least intention of being controversial, and only with a view to contributing some points to the interesting problem of rheumatism and appendicitis, I should like to record that I have never yet in a case of fatal rheumatism found the appendix vermiformis diseased. This does not in any way prove that appendicitis may not be rheumatic, but I think it is interesting when it is remembered how frequently these two diseases occur in this country. It may be that others who have looked for this point may have had an experience different to my own, and it is possible that when the rheumatic infection attacks the appendix it spares the other viscera. I am also confident that in children who have had rheumatic fever once, twice, or even frequently, appendicitis is very rare—so rare, in fact, that it attracts immediate attention. One case I have seen occurring with chorea, and one case I also recall sent up for immediate operation. Advanced heart disease made one hesitate, and the condition, whatever it was, got well. Salicylates were given, and the therapeutic result might have been claimed as proof of a rheumatic appendicitis. This child, however, died in another attack of acute rheumatism, and the appendix was found normal, which considering the acute illness of the child in the first attack, appeared to me a very unlikely event.

Such cases of peritonitis as I have seen of rheumatic origin, and occurring in fatal rheumatism, have been confined to the upper half of the abdomen, and particularly

to the region of the liver and spleen. As I have pointed out before, rheumatism, when it affects in children the right hip, either alone or with perhaps a slight arthritis of some small joint such as an interphalangeal, may closely simulate appendicitis. There is fever, the right limb is slightly flexed, and the pain referred above Poupart's ligament. Surgeons in my knowledge have come desperately close to making their familiar incision, which on these occasions would have brought them to the wrong side of the acetabular cavity. Lastly, arthritis we know may occur in appendicitis, and in those cases in particular in which the local signs are indefinite. Although this is pyaemic, much relief may at first be obtained from salicylate treatment, particularly if the arthritic pyaemia is mild in type.—I am, etc.,

London, W., Jan. 19th.

F. J. PONTON.

TREATMENT OF ACUTE AND SUBACUTE RHEUMATISM.

SIR,—I have read with much interest Dr. D. B. Lees's very instructive article on the effective treatment of acute and subacute rheumatism, in the *JOURNAL* of January 16th, a subject upon which his able and prolonged investigations have given him every right to speak with authority. With his general conclusion that we now give too small doses of sodium salicylate in rheumatic fever I am quite in accord, and look upon our present practice as the extreme swing of the pendulum away from the excessive doses used when the drug was first introduced. The rebound was chiefly brought about, I think, by the comparative frequency of salicylate delirium which followed the routine exhibition of 20 grains every hour or two hours. On one point in his paper Dr. Lees will, I trust, forgive me if I join issue with him. He says:

We must give up the conception of acute rheumatism as a form of arthritis of adults, with the occasional metastasis to the heart, and with certain "peculiarities" when it occurs in childhood.

In justice to the physicians at St. Thomas's in the late Seventies and early Eighties, I must say they never taught us such a conception, but impressed upon us the fact that acute rheumatism was a constitutional malady, nearly allied to the ordinary "specific febrile disorders." One quotation from a paper I wrote in 1886* on *The Nature of Acute Pneumonia in Children* will be sufficient to prove my contention; in it I say:

All will admit that the lung lesion in acute pneumonia is no more characteristic of this state than is the joint lesion in rheumatic fever; but we should consider it a distinct retrograde step were we to style this latter acute arthritis. The clinical picture of rheumatic fever is a far more complex one than is that of acute arthritis; it includes in addition pneumonia, pleurisy, pericarditis, endocarditis, and a peculiar sweat, as well as a remarkable subservience to salicin and a tendency to high temperature, etc. Now the clinical picture of "acute pneumonia" is more complex still;

and so on.—I am, etc.,

Birmingham, Jan. 16th.

ARTHUR FOXWELL.

THE FLEA AS A CARRIER OF PLAGUE.

SIR,—In the *JOURNAL* of January 16th there are two letters criticizing mine, referring to the flea as a carrier of plague, in the *BRITISH MEDICAL JOURNAL* of January 9th.

A. A. M. asks have I not made a mistake in reference to (1) the covering of the Ark; (2) it does not appear that the coverings of the tabernacle were carried in the incident referred to. A. A. M. has studied Exod. xxv, 11, and so has found out that the Ark was overlaid with pure gold. But, if he had extended his reading to Numbers iv, 5, 6-14, he would have also read:

And when the camp setteth forward, Aaron shall come, and his sons, and they shall take down the covering vail, and cover the ark of testimony with it. And shall put thereon the covering of badgers' skins, and shall spread over it a cloth wholly of blue, etc., etc.

The historic incident to which I referred was preceded by the battle of Ebenezer, in which the Israelites were defeated by the Philistines. In order to raise a religious enthusiasm in their defeated troops and encourage them for a renewal of the conflict, the elders of Israel sent for the Ark to Shiloh. Naturally, under such circumstances, everything that priestcraft and ecclesiastical ritual could

* *Practitioner*, July, 1886.

do would be done to impress the wavering minds of the discomfited army with the certainty of invisible help. It raised the drooping spirits, for "they shouted with a great shout, so that the earth rang again." Numbers iv, 5, 6, therefore, makes it clear that when the Ark appeared in public it carried its trappings, and especially in such a case as the present, "when the camp setteth forward" to battle.

Bearing on the hypnotic influence of such sacred emblems, I may cite the example of the Labarum in the armies of Constantine, the image of Christ carried by the troops of Justinian, and the Holy Lance with the Crusaders at Antioch. The Mohammedans had their sacred standard, and the Sassanian monarchs of Persia the blacksmith's apron on a flagstaff, etc.

Dr. Stansfield has a doubt that the Hebrew word *akhbar* covered both rat and mouse. Well, there is in Biblical Hebrew only one word for both these animals, just as in the Egyptian language there was the common word *Pennu*, in the Greek *μῦς*, and in the Latin *mus*, for mouse and rat. If the "reverend gentleman who understands Hebrew" will give me the special word for rat, I shall be obliged. The fact is these words cover several species of rodents, and not mice, and rats, and field mice only, and could equally well be translated otherwise.

The bearings of my original letter were:

1. That it has been proved by actual experiment that the flea transmits plague from rat to rat.

2. If only one were permitted to make a criminal more useful in his death than in his life, then it could also be proved, by direct test, that the flea carries plague from the rat to man.

3. Failing No. 2, which, owing to the frailties of some of the weaker brethren, is impossible at the present time, I suggest the incidents following on the capture of the Ark as a natural verification of the transmission of the pestilence by fleas, and, in the instance of Beth-shemesh, without any human contact whatever.

I do not wish to play upon or cavil with words, but simply to direct thoughtful minds to what has been, for I hold, with Chrysostom, that "it is not names which give confidence in things, but things which give confidence in names."—I am, etc.,

London, W., Jan. 19th.

R. HAVELOCK CHARLES.

P.S.—Some people may say that the rat was unknown to the Egyptians, Greeks, Hebrews, and Romans. The reply to this is: (1) That fossil remains of both rats and mice have been found in the pleistocene deposits of Europe and Asia. (2) Amongst Egyptian papyri there is one of a satirical nature, in which is a picture of a "Battle between the Cats and the Rats." I am indebted to one of the first authorities of the day on these matters for the following note:

There is another word, to which some of the earlier scholars attached the meaning "rat," in Isaiah ii, 20, but it is now generally rendered "mole." This word occurs here only, and alike its spelling and meaning are doubtful. In the late Hebrew there were two other words, *qamri* and *sor*, used in addition to *akhbar* to signify "mouse." If the rat was known to the Hebrews, they had apparently no other word but *akhbar* to designate it. The last word was used also in Western Aramaic. In Syriac there were at least two words for "rat," but there is no root in Hebrew corresponding to these words.

R. H. C.

THE HOME TREATMENT OF SCARLET FEVER.

SIR,—I was interested to see Dr. Robert Milne's letter in the BRITISH MEDICAL JOURNAL of January 16th on the above subject, and also a former communication from him (vol. ii, 1908, p. 1333), in which he referred to my father, Mr. J. Brendon Curgenven, in connexion with this treatment.

Over twenty years ago my father first suggested the inunction of eucalyptus oil in scarlatina; he wrote to the medical papers, read a paper before the Epidemiological Society, and also, I think, before the Society of Medical Officers of Health. A certain number of medical men took up the matter, but our profession is conservative, and the fear of infection in a serious illness like scarlet fever is so great in the public mind, that there was always difficulty in fighting against the wet sheet and the six weeks' isolation. I was in practice with my father when we first tried this treatment. There can be no doubt

that it mitigates the symptoms and lessens the chance of, even if it does not prevent, complications, besides preventing the spread of infection.

With Dr. Milne I shall be glad to see the treatment thoroughly tried, for if it be found, as both he and I contend, to do away with the long infectious stage during desquamation, it will save the country large sums of money in connexion with the isolation hospitals.

Although Dr. Milne mentioned my father in his first communication, I notice that throughout his last he refers to the treatment as if it were his own, which I think is hardly right. The credit of having introduced it certainly belongs to my father.

I agree with Dr. Milne with regard to measles. I have tried eucalyptus in a good many cases without benefit, and never found it prevent the spread of the disease.—I am, etc.,

London, W., Jan. 17th.

J. SADLER CURGENVEN.

VINCENT'S ANGINA.

SIR,—The evidence originally given by Professor Vincent in favour of the pathogenicity of the fusiform bacillus and spirillum described by him has always seemed to me to be weak. He himself describes one clinical type, in which the fusiform bacillus is found, as being much like diphtheria. Another form, to which he has given the name "ulcerative membranous," is in some cases at least strongly suggestive of scarlatina; indeed, there may be a scarlatinal erythema, a pseudo-rheumatism, and later albuminuria and endocarditis, though Professor Vincent attributes these to a superadded infection, usually streptococci. The majority of the cases, however, described as ulcerative membranous seems to be indistinguishable clinically from what are usually called septic throats.

Yet another form is described which closely resembles syphilitic ulceration; but though Professor Vincent states that the bacteriological examination will make the diagnosis clear, he adds that it is important to know that secondary syphilitic lesions may be the site of a superadded infection by the spirillum and fusiform bacillus. These points are to be found in a paper by Professor Vincent in the *Lancet* for May 13th, 1905.

Thus such a diversity of effect is attributed to a common cause that it is difficult to accept the reasoning as sound. Strong evidence would be necessary, and this I do not think has been produced.

In the article to which Dr. Nash kindly referred I gave, with my own experience of the examination of films, a brief account of the experimental evidence, so far as I could trace it, as to the pathogenicity of the organisms.

Dr. Wyatt Wingrave's valuable observations show how widely distributed such organisms must be.—I am, etc.,

Blackburn, Jan. 16th.

MILES B. ARNOLD.

THE ST. JOHN AMBULANCE ASSOCIATION AND THE MEDICAL PROFESSION.

SIR,—I quite agree with the remarks of Dr. Edward Jepson concerning his experience and views of the St. John Ambulance Association and the method of distribution of their honours.

Some time ago one of the officials of the Order attended a function for the presentation of prizes, and announced the fact that "H.R.H. the Prince of Wales, Grand Prior of the Order, had expressed his approval and sanctioned distinction for a certain medical man to be made a Knight of Justice," an irregular procedure surely, as it had not appeared in the *Gazette* at that time, but a very proper recognition for a medical man who gives his time and services in the way so very many do; but the point of the whole thing was this, as Dr. Jepson shows, it was a question of "kissing going by favour." There were many medical men who had done a great deal more in the way of lecturing and routine work who had been passed over and had not "caught the eye" of the secretary of the Order, as some would have it.

Quite recently there was a case of a retired army doctor who had put in not more than two or three years' work in the ordinary way for the association, and was made a Knight of Justice.

Consistency seems to be the one thing wanting in the actions of those in authority at St. John's Gate.—I am, etc.,

January 18th.

ANOTHER LECTURER.

DR. DOUGLAS ARGYLL ROBERTSON.

SIR,—In the excellent notices I have seen of my friend, the late Douglas Argyll Robertson (I believe I have not seen them all), there is no mention of the fact that he was one of the first, if not the first, to teach what was afterwards called "practical physiology" to classes of medical students. This was in Edinburgh, in connexion with the Chair of Physiology, about 1865, while the chair was held by John Hughes Bennett. The origin of this class is interesting historically. For many years John Hughes Bennett had given a course of histology and the application of the microscope to medicine. Early in the Sixties, John Goodsir, the anatomist, and, it is only just to add, the physiologist, was in the habit of bringing home new and strange physiological instruments from Germany—things called myographs, kymographs, non-polarizable electrodes, ophthalmometers, recording drums, etc.—hitherto unknown in Edinburgh or elsewhere in this country, so far as I am aware. This was the washing of the Helmholtz-Du Bois-Reymond-Ludwig ware on the shores of this country. These instruments soon made their appearance in the anatomical rooms. Bennett expostulated with Goodsir, and Goodsir replied, "Well, Dr. Bennett, they are instruments you should have; take them over at the price I paid for them." This Bennett promptly did, and so arose the Museum of the Physiological Department of the University of Edinburgh.

Argyll Robertson at this time became Bennett's assistant, and although, as is correctly stated in several notices, he determined to be an ophthalmologist, he taught a practical class for several summer sessions, introducing the chemical analysis of urine, the volumetric estimation of sugar, phosphates, and urea, and also a short course of demonstrations in electro-physiology, the use of electrical apparatus, and the elementary physiology of muscle and nerve. This he by and by handed over to William Rutherford, who systematized and extended the course, and to whom much credit should be given. I am proud to say that I came next in lineal succession, and I well recollect that when I became Bennett's assistant (1869-70) and had to face this practical class I received invaluable aid from both Argyll Robertson and William Rutherford. "Argyll," as we loved to call him at that time, presented me with several books on physiology of a practical character, which are now in the library of the Physiological Department of the University of Glasgow—I am, etc.,

Stonehaven, Jan. 18th.

JOHN G. MCKENDRICK.

THE HUNTERIAN SOCIETY'S MEDAL.

SIR,—Last June you were good enough to insert a notice that the Hunterian Society had decided to award a silver medal annually for the best essay by a general practitioner embodying the results of his own investigations. In view of the number of applications received for particulars of the competition I venture to send you the following details:

The competition is open to all registered general practitioners in the United Kingdom and the Channel Islands. The subject of the essay can be chosen by the candidate, but must fall within the province of medicine, surgery, or midwifery.

The essay must be unpublished and original, and based on the candidate's own observations, except for references to the literature of the subject. Observations may be included in the essay which have been made by means of special methods not available in ordinary practice, by workers engaged in these special methods, but the candidate must duly acknowledge the source of his information. Two type-written copies of the essay must be sent in, together with any material which the candidate may desire to submit. The essay must be marked by a motto and accompanied by a sealed envelope containing the candidate's name, address, and qualifications, and a signed statement that he is a general practitioner. On the outside of the envelope the motto must also be inscribed. The last day for sending in essays for the present competition is December 31st, 1909.—I am, etc.,

W. LANGDON BROWN.

UNIVERSITY OF LONDON.

OFFICERS' TRAINING CORPS.

THE Military Education Committee appointed by the Senate to manage the university contingent of the Officers' Training Corps has received the sanction of the Army Council to the formation of a contingent which shall include an infantry, an engineer, and a medical unit, these units being composed of three companies of infantry, one company of engineers, and two sections of a field ambulance respectively. It is expected that additional companies will be formed at a later date. The rules for the contingent provide that admission to the contingent shall be restricted to gentlemen who are members of the University of London, or are non-matriculated students pursuing a regular course in schools of the university, save that power is reserved to the commanding officer in special cases to admit gentlemen who, though not comprised in either of the foregoing categories, are desirous of gaining the certificates of proficiency obtainable in the Officers' Training Corps. The corps is intended for the preliminary training of young men with a view to their qualifying for commissions in the Special Reserve of Officers, or the Territorial Force, and membership of the corps is restricted by the Army Council to British subjects of pure European descent. Cadets enrol normally for two years, but enrolment for one year may be permitted under special conditions in the present session. After the second year of membership cadets may re-engage annually for the purpose of obtaining Certificates A or B, but they will not, unless in exceptional circumstances, be permitted to remain as cadets for more than four years. Two of the infantry companies will be located at University College and King's College respectively; the location of the third company is not at present fixed. The engineer company will not be attached to any particular school of the university. The members of the medical unit will be drawn from the medical schools attached to the university, more than a hundred students from Guy's, St. Bartholomew's, St. Thomas's, University College, King's College, and other medical schools having already applied for membership. Enrolment in the contingent will begin immediately. With regard to head quarters, no arrangements have yet been made, and the training will be carried out for the present in the colleges attached to the university; the consideration of this question, as of other questions, such as the possibility of organizing cavalry and artillery units, has been postponed pending the appointment of the adjutant and the establishment of the infantry, engineer, and medical units.

UNIVERSITY OF ABERDEEN.

THE PROFESSOR PIRIE MEMORIAL.

THE movement which was started some time ago to provide a memorial to the late Professor Pirie has met with substantial success, and at a meeting of subscribers held in Marischal College, on January 15th, it was resolved that the memorial should, with the sanction of the University authorities, take the form of a stained-glass window in the ante-chapel of King's College.

UNIVERSITY COURT.

The Aberdeen University Court met at Marischal College on January 12th, Principal Lang presiding. The Secretary submitted an intimation from the Rector, Mr. Asquith, that he had appointed Sir John Fleming as his assessor in the University Court. The Principal welcomed Sir John Fleming, who had already, some years ago, while Lord Provost of the City, been a member of the Court and had done excellent services for the University while the great extension scheme was in progress. Afterwards the Principal referred to the retirement of Dr. James E. Crombie from the assessorship which he had occupied with so much distinction and benefit to the University particularly in connexion with the Quatercentenary celebrations in 1906. It was unanimously decided that a copy of the following minute should be sent to Dr. Crombie:

The services of James E. Crombie, Esq., LL.D., as Rector's Assessor having for the present at least terminated, the University Court hereby records its profound and most grateful appreciation of Dr. Crombie's wise counsel, ever ready co-operation, and unobtrusive but abounding liberality. During the nine years in which he was a member of the Court he was seldom absent from its meetings and he took an active interest in all its work. The University Court recalls with special emphasis his unwearying labours in connexion with the Quatercentenary celebrations, the success of which was largely due to his organizing genius. In Dr. Crombie the students of the University found a most reliable adviser and a most devoted and efficient friend. The University Court offers this imperfect tribute to the energy and the personal qualities of one with whom it was a privilege and an honour to be associated.

UNIVERSITY OF BIRMINGHAM.

THE total number of students who have entered the university this session is 210 as against 201 for 1907-8. There has been an increase from 79 to 85 in the Medical Faculty, if occasional students are included, such as those in Public Health. Excluding occasional students, those who have entered for the full course number 34, as against 27 last year. Among the other departments there is only a slight increase in those of Commerce and Science.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At a meeting of Council on January 14th, Mr. Henry Morris, President, in the chair, modifications in the College By-laws with a view to the admission of women to the conjoint examination were considered, and referred to a committee for future report.

University of Birmingham.

Mr. H. T. Butlin was reappointed a member of the Court of Governors of the University of Birmingham for three years expiring January 1st, 1912.

Board of Examiners in Dental Surgery.

The vacancy occasioned on this Board by the retirement of Mr. G. H. Makins will be filled up at the next meeting of Council. Mr. Makins is not eligible for re-election.

CONJOINT BOARD IN ENGLAND.

The following candidates have been approved at the examination indicated:

FIRST COLLEGE, PARTS I AND II (Chemistry and Physics).—E. B. Argles, R. A. Ransbury, J. D. Bangay, H. W. Barnes, W. A. H. Bell, H. C. Bingham, W. H. Bland, R. C. Briscoe, E. A. Brock, R. G. Brown, T. H. Brown, G. Cock, R. I. Dacre, H. R. Dive, S. O. Dolan, J. D. Driberg, H. Dudley, A. G. B. Fenwick, L. E. Forster, E. D. Fountain, S. S. Greaves, C. A. Haynes, F. T. Hill, G. G. Jack, H. D. Lamb, D. Lewis, J. Lloyd, O. G. Maglinski, A. W. Matthew, G. W. Maw, H. M. A. Menagé, W. Morris, H. H. P. Morton, F. H. Mosse, N. S. Nairne, L. E. Napier, H. B. Owens, T. H. Parsons, A. S. Plant, C. S. Ramsay-Hill, J. Rashad, J. Rawson, J. E. Rawson, J. E. Richards, J. E. Rivera, G. Robinson, J. A. Robinson, F. Roux, F. Simpson, C. R. Smith, G. S. Stathers, J. Totton, C. G. C. Vawdrey, L. G. White, F. H. Woods.

Part III (Elementary Biology).—E. V. Briscoe, R. C. Briscoe, G. Cock, J. S. Cocks, R. Curle, W. K. Fry, T. W. Hancock, F. W. Herbert, J. S. Higgs, J. W. McIntosh, C. H. Medlock, J. Millard, T. H. Parsons, C. H. Phillips, A. S. Plant, P. H. Rawson, G. D. Robertson, G. Robinson, F. Roux, T. S. Stafford, C. de B. Thomson, J. Totton, L. D. Wright.

PART IV (Practical Pharmacy).—H. R. L. Allott, J. V. O. Andrew, H. J. Bates, E. F. W. Buckell, J. Capell, T. Cock, M. Donaldson, R. H. W. Fisher, M. Graves, G. H. G. Griffiths, L. S. M. Habich, V. P. Hutchinson, F. Kahlenberg, M. M. Khan, H. Lee, W. E. Levinson, F. G. Lioyd, R. H. Mawhood, J. J. W. Methven, A. Morgan, F. Morris, A. B. Peggrew, C. M. Plimpre, E. D. W. Reid, L. M. Routh, C. P. C. Sargent, F. S. Sowers, J. E. Tilling, R. T. Timbers, M. C. Wall, R. J. Wooster, J. F. W. Weyer.

SECOND COLLEGE (Anatomy and Physiology).—N. H. Bamboat, R. S. de C. Bennett, W. H. Boyd, R. P. Brothie, S. A. Burn, C. G. Colver, A. G. W. Compton, J. H. Cumming, A. K. Dalal, H. B. F. Fainalson, P. T. Fisher, F. Garratt, K. B. Greenwood, J. E. Hemper, A. Jones, G. L. Jones, B. R. Khanna, A. B. Kramer, W. M. Landon, D. McRae, A. F. C. Martyn, L. Milton, W. F. Morgan, W. H. Parr, W. S. J. Peiris, C. A. Pereira, N. P. Pritchard, T. S. Rajan, J. M. Redding, T. C. Reeves, D. Scott, B. Z. Shah, J. M. Shah, P. Smith, J. R. C. Stephens, J. L. Stewart, L. C. Watkins-Baker, A. M. Werapremala.

* Passed in Part I only.

† Passed in Part II only.

Contract Practice.

REPORT OF THE CHIEF REGISTRAR OF FRIENDLY SOCIETIES.

PART A. Of the Report of the Chief Registrar of Friendly Societies for the year ending December 31st, 1907, has recently been issued. If some what belated in its appearance, the report certainly makes up for this by its completeness and the care with which its statistics have been compiled. As the registrar points out, the functions of his office are very much wider than they are popularly supposed to be, since they are not restricted to the registration and control of friendly societies alone, but are concerned with building societies, co-operative societies, trade unions, loan societies, and others, and with the administration of the very numerous Acts of Parliament governing these institutions. In view of the enormous sums of money handled by these societies in the aggregate—sums largely representing the thrift of the working population of the country—it will be obvious that the activities of this office are of the first importance to the country as a whole. A few years ago there was great uneasiness, almost amounting to panic, concerning the financial condition of the friendly societies as a whole. The present report shows a certain amount of improvement in this respect, although the position is still far from satisfactory. In the case of 506 societies from which valuations had been received, there was a net gain in value of £122,738, but against this must be set the fact that only 35 per cent. of the societies could show a surplus and 65 per cent. disclose a deficit. In every case where deficits have been wiped out or reduced, this has been accomplished by the members making a voluntary sacrifice either in the way of increased contributions or of a reduction of benefits. The unsatisfactory financial position appears to be to a great extent due to the excessive management expenses, which in too many cases are partly met by an improper transfer of money from benefit funds to management

funds. Thus it is shown that of every £1,000 expended by the "collecting societies" £502 are applied to management expenses; yet, in spite of this, no less than 9 out of 62 of these societies show a deficiency in the management fund.

From the point of view of medical men engaged in contract practice the report is very disappointing. In every case where "medical aid and medicine" is mentioned in the tables given this is lumped with "sick pay" or sick or accident benefit, so that the report fails to give any data by which the proportion of funds applied to the payment of medical men can be estimated. This is the more to be regretted as many of the tables give comparative figures of expenditure for various years, and had this item been separately tabulated the figures would have been of the utmost value to those who are engaged in endeavouring to improve the conditions of contract practice.

The only place in which the figures for medical attendance are given is in the Report of the Registrar of Friendly Societies for New South Wales, which forms one of the appendices to the report. According to this, "an amount of £90,698 was paid away during 1906 to provide for medical attendance and medicine. This represents an average cost of 17s. 6d. per head of mean membership." Unfortunately the tables do not give us the average amount of contributions by members of these New South Wales societies, but the capital per member works out at £9 8s. 6d.

It would perhaps be well for the British Medical Association to consider whether it should not approach the Registrar of Friendly Societies with a view to ascertaining whether it would be possible for him in future to obtain separate figures as to payments made to medical men in the case of those societies which provide medical attendance.

The Serbices.

EDINBURGH TERRITORIAL HOSPITAL.

The first mess dinner in connexion with the 2nd Scottish General Hospital of the Territorial Force was held in Edinburgh on the evening of January 12th. There were about fifty officers present, including as guests Mr. Haldane, General Sir Edward Leach, and several others. The administrator of the hospital (Lieutenant-Colonel Wyville Thomson), in proposing Mr. Haldane's health, stated that this was the first time the officers of the hospital had met together. Speaking of the progress of the hospital, he said that the personnel was complete with the exception of a quartermaster, whose place could be filled at any moment if it was necessary; the officers' mail-and-file were complete. The personnel was not only complete but he believed double the number could have been recruited had it been necessary. A very high class of enthusiastic and intelligent men, who represented all the professions and trades likely to be of service in the complicated business of running a field hospital, had been enlisted. He did not believe there existed a finer body of men for the special purpose for which they had been enrolled. In order to head quarters, the hospital was at present in progress for premises which would be convenient to the university and Royal Infirmary. In the matter of drill and instruction there was a difficulty, because the authorities had not seen their way to give an instructor, and the help of others had to be asked, which was neither pleasant nor right. Seventy-five nurses had been enrolled, and it was expected that by the end of the month the full complement of 120 nurses would be obtained. As to the equipment, Mr. Haldane, in reply, said his situation were points that had not yet been settled. Mr. Haldane, in his reply, in touching upon this matter, said that the decision would be left to those on the spot. The first problem in army organization was to devise the most perfect organization. The Territorial system was founded on scientific principles. The toast of success to the second Scottish General Hospital was proposed by Lieutenant-General Sir Edward Leach, and Lieutenant-Colonel Gibson, Senior Physician, who replied, referred to the debt of gratitude owing to Sir George Beaton and Professor Cunningham.

TERRITORIAL FORCE.

Uniform of Officers.

X. Y. Z. writes: I think your correspondent "A. A. M." on p. 193 of the BRITISH MEDICAL JOURNAL, should know that paragraph 408 of the Territorial Force Regulations says, that "claims of officers whose transfer to the Territorial Force necessitates an alteration of uniform may be specially considered by the Army Council for such portion of the grant as will not exceed actual expenditure on the purchase or alteration of outfit." Paragraph 405 says: "The Army Council will . . . consider the claim of an officer transferred . . . to such portion of the grant as would not exceed his actual expenditure for the purchase or alteration of his new outfit."

What "A. A. M." should do is to make application through his commanding officer to the cashier of the command his unit is in for the £20, and he would get a ruling on the point

definitely as to what he would be allowed; or another way would be to produce receipts for purchase of the new uniform, and forward them through the same channel to the cashier of the command.

Remuneration for Medical Examination of Recruits.

Questions were asked in the House of Commons as well as the House of Lords on this matter, but in such a way that no satisfaction was obtained. Paragraph 611 of the Territorial Force Regulations says that the County Associations will be allowed a sum of 1s. for the medical examination of each recruit. I understand that the associations will not pay this to Territorial medical officers unless they make special application for the fee.

Personally, I hold that if a medical man joins the Royal Army Medical Corps, it is part of his duty to medically inspect recruits, and should expect no fee for doing so; but that if a civilian medical practitioner is called in to do so, the fee of 1s. is totally inadequate for the work required of him. With the exception of examination of urine, it is equally as exacting as for life insurance properly to examine recruits in accordance with directions as laid down.

The fee should be at least 2s. 6d. for a civil medical practitioner, and I think the Naval and Military Committee of the Association should make representation to the Director-General of the Army Medical Department on the matter.

Medico-Legal.

AN ACTION FOR SLANDER.

On Wednesday last the Court of Appeal Lords Justices Vaughan Williams, Farwell, and Kennedy commenced the hearing of an application by Dr. George Lawrence, of 61, St. Fillan's Road, Catford, for the new trial of an action brought against him by John Papa Nicholas, of 87, Down Hill Road, Hither Green, for slander. The case had been tried by Mr. Justice Grantham and a special jury in December last, when the plaintiff was awarded £200 damages, the jury adding a rider to the effect that the name of the plaintiff ought to be restored to the *Medical Register*. The hearing of the appeal had been expected. The grounds of appeal were the non-reception of evidence tendered on behalf of the defendant, and misdirection.

Mr. Lush and Mr. Neilson (instructed by the Solicitor to the London and Counties Medical Protection Society) were for the appellant; Mr. F. E. Smith, K.C., and Mr. Hogg for the respondent.

At the conclusion of the arguments on Thursday the court ordered a new trial.

CERTIFICATES TO MIDWIFE CANDIDATES.

The case to which reference was made on January 9th, p. 116, reached its final stage on January 14th, when the woman in question was charged at the Central Criminal Court with having obtained admission to the Midwives' Roll by a certificate which she knew to be false, and pleaded guilty. In mitigation of penalty her counsel urged that it was not necessary under the Act that she should furnish a certificate covering more than a year previous to her application, and that if she had intended to act in a fraudulent manner she would not have put forward a certificate which covered the early period of her career, during which she had been twice tried for murder. The Recorder, after remarking that the prosecution was a very proper one to institute, deferred sentence until next session, directing that the defendant should meanwhile be detained in custody.

FALSE DEATH CERTIFICATES.

THE two women who figured in the inquest at Lincoln, of which an account was given in these columns at page 190, January 16th, were charged in the magisterial court on January 14th in the same city with wilfully making false declarations. They pleaded "not guilty," but it was proved against them that they had secured the burial of the child by alleging that they had been present at its birth, and that it was stillborn; whereas neither of them was really present at the birth, and neither of them knew whether the child was born alive or dead. It was shown at the previous proceedings that the child from a medical point of view was born alive. It was also shown that one of the women had signed her declaration with a name which was not her own. The court found the defendants guilty, and fined each of them £2 17s. including costs, or, in default, one month's imprisonment. One of the women was a registered midwife.

INDUSTRIAL INSURANCE COMPANIES.

MIDLANDS writes: I saw a poor patient about a year ago, diagnosed chronic Bright's disease, with hypertrophied heart and enlarged liver. I told the patient the serious condition he was in, and warned wife and children that he would not live very long. Since then he has amused himself by doing a little light work at intervals. A short time ago he became very ill, and after a week or so died of uræmia. About eight or nine months ago the patient got insured in two of the companies which will accept candidates without medical insurance. During the past week I have been pestered by the superintendents, assistant superintendents, agents, etc., of

these companies, who wish to find out various details. I have refused to give any information, but stated that I would give any information they might wish providing the son and wife consented and that I charged a fee. Have I done correctly? I should be glad to know what is the usual custom in these difficulties, which must be fairly common with all general practitioners.

* * This case illustrates the manner in which some industrial insurance companies carry on their business, a subject upon which the county court judge at Tunstall expressed himself very decidedly, as reported in the *JOURNAL* of January 16th, p. 190. We think our correspondent was right to refuse to answer any questions put to him by the company without the consent of the deceased person's family, and further that he is entitled to be paid by the company for any information given to it.

FOUR-LAW MEDICAL OFFICER AND THE COMMISSION OF THE PEACE.

DR. JNO. MILSON REODES, J.P. (Ivy Lodge, Didsbury), writes: I quite agree with your answer to "Rusticus" in the *JOURNAL* of January 16th, p. 190, and should be pleased to furnish him if he likes with the names of and county for which a clerk to the guardians was two years ago appointed one of the Justices of the Peace.

COMPENSATION FOR PERMANENT DISABILITY.

M.D. writes: I am attending a schoolmistress suffering from neuritis and muscular atrophy of the right arm with ankylosis of the right shoulder, secondary to an accident some twelve months ago from falling in the playground during school hours. She did not give up work until a fortnight ago, when she sent in her resignation. She will be permanently incapacitated, and I wish to know if she can claim compensation from the local education authority. At present this authority denies liability, on the ground that the patient did not have to give up work for so long; but I cannot think this is a valid objection.

* * The chief difficulty in the way of a successful claim would be the absence of notice. Proceedings for the recovery of compensation shall not be maintainable unless notice has been given as soon as practicable after the happening of the accident. Absence of notice is not, however, a bar to a successful claim if it can be shown that the employer is not thereby prejudiced, or if there is reasonable cause for not giving such notice. The question whether the employer is prejudiced or whether there is reasonable cause for the lack of notice is for the court to decide. Our correspondent should recommend his patient to see a solicitor.

NOTICE OF TERMINATION OF APPOINTMENT.

PECKHAM wishes to know how far he is liable legally, having accepted a post under a public authority on the agreement to give three months' notice on leaving, if he insists on leaving after two months' notice, and offering to put in a locum tenens for the third month.

* * Our correspondent is legally bound to give the three months' notice. In default, he might be sued for any extra expense caused to the authority by the legal notice not having been given. His proper course is to approach the authority in question, and point out the necessity of his leaving, and offer to furnish a suitable substitute. Under such circumstances his offer would most probably be accepted.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

INTIMATION OF CHANGE OF ADDRESS.

G. G. complains, as have so many before, that he has received a card notifying the change of address of a West End physician who is entirely unknown to him and asks whether it is usual.

* * We have often pointed out the objection there is to sending out such notices broadcast as it is certain to be regarded as an advertisement although it is quite possible that there was no such intention.

DUTIES OF CERTIFYING FACTORY SURGEONS.

PIRATE.—In reply to our correspondent's further inquiry we can only say that it is clear that B. has no right to attend the injured person by virtue of his office of certifying surgeon, and equally clear that he should not abuse such office by touting for work; but it is impossible to judge B.'s conduct without knowing by whose authority and under what circumstances the treatment was undertaken.

A DISCLAIMER.

DR. R. J. COLLIE (London, W.) writes: At the request of the Stratford Division of the British Medical Association, some few weeks ago I read a paper entitled *Medical Evidence and the Laws Relating to Compensation for Personal Injury*. A short time afterwards the editor of the *Medical Magazine* wrote asking permission to publish the paper, and I agreed. In the article I took occasion to deprecate the increasing prostitution of medical evidence, which, as you are aware, is confined to an infinitesimally small proportion of the profession. I have been greatly annoyed to see in the daily press certain isolated quotations from my article, which, without the context, are calculated to give a wholly unfair view of the position. The object of this letter is to state that I have taken no part in the publicity given to the article, nor was it done with my sanction, and that, while I am anxious that those who lay themselves open to the charge of unfair dealing should be exposed, the lay press is under no circumstances the medium that I should have voluntarily chosen for this purpose. I have communicated with the office of the *Medical Magazine*, and am assured that it has in no way been in communication with the lay press.

THE ETIQUETTE OF CALLING BY A NEWCOMER.

LANCASHIRE asks whether it was a breach of medical etiquette for a newcomer to be five or six weeks before calling upon the other resident doctor? It is suggested that he may have had much to do in the work of settling himself in a new house in a new place.

*. There is no limit to the time within which such a call should be made. All that can be said is the sooner the better, as until this obligation of medical courtesy has been fulfilled there may be a doubt as to whether the newcomer wishes to be on friendly terms.

DEATHS FOLLOWING ACCIDENT.

P. is medical officer to a workhouse. An old woman who was an inmate fell in the night and broke her leg, and died three days afterwards of shock. P. reported the case to the coroner, who held an inquest. It has been suggested that P.'s action was unnecessary and that he might have given a certificate in the ordinary way. Would P. have been justified in doing so?

*. If P. had given a certificate of death it would have been referred to the coroner, who would have held the inquest, as the death arose from injury. In such cases the certificate of death should be withheld and the coroner communicated with.

POST-MORTEM EXAMINATIONS FOR CORONERS IN IRELAND.

R. C. P.—The coroners' law is the same in Ireland as in England. In England the London County Council and some other authorities pay fees for evidence given in coroners' courts by resident medical officers of workhouses. At Bradford the corporation has authorized the payment of fees in the case of persons dying in the workhouse outside its infirmary or imbecile wards. The subject is now engaging the attention of the Medico-Political Committee of the British Medical Association, and we may call our correspondent's attention to the letter of Dr. George Walker published in the *JOURNAL* of December 5th, 1908, p. 1721. So far as we are aware no medical officer of a workhouse or county infirmary in Ireland has obtained a fee for making a post-mortem examination or giving evidence regarding the death of any person dying in either institution. Under these circumstances it would not be wise in our opinion for a medical coroner in Ireland to pay a fee to a county infirmary surgeon, as his account would probably be objected to by the county council auditor and the fee paid disallowed.

SUPERSESSON.

B. is called to a child suffering from acute illness. After attending for some time he discovers that A., who is ill, has been the regular attendant of the family. When A. had recovered, B. asked the parents if they would wish the case to be handed over to A., but they requested B. to continue in attendance. B. said he did not wish to attend unless the parents were quite certain in their own minds, and in the evening he received a polite note saying that as A. had been their medical attendant for five years it would be best for him to take charge of the child. B. then withdrew. A. now holds that B.'s conduct was unethical, as he was prepared to continue in attendance if the parents had wished him to do so. B., on the other hand, considers that he has done even more than could be ethically required of him. We are asked to say who is right.

*. Assuming the above statement of facts to be correct we think that by offering to withdraw as soon as A. had recovered, B. showed that he had no wish to take advantage of A.'s temporary inability to attend to his practice.

THE MEDICAL PROFESSION AND THE SALE OF WINES AND SPIRITS.

R. B. M.—We can sympathize with the feelings of our correspondent in receiving the typewritten letter he encloses from

a firm of local wine merchants requesting his recommendation of their goods, but we are glad to see that there is no suggestion of the offer of any corrupt inducement which too often accompanied such communications before the passing of the Prevention of Corruption Act.

Obituary.

JOHN DEWAR, M.B., C.M., J.P.,

PORTREE, SKYE.

We regret to have to announce the death of Dr. Dewar of Portree, which occurred on January 13th. Up to within a fortnight of his death Dr. Dewar was able to discharge his duties, but symptoms of what appeared to be enteric fever then set in. Subsequently a positive diagnosis of this disease was departed from, and symptoms of cerebral disease developed which ended fatally.

John Dewar was born in Easdale, one of the islands of the west of Inverness-shire, forty-seven years ago. He graduated at Glasgow University in 1887, taking the degrees of M.B. and C.M. After practising a short time at Dunvegan he settled in Portree about nineteen years ago. He had an extensive practice in the island, and held many public appointments. He was Medical Officer under the Parish Councils of Portree and South Skizort, Public Health Officer under the Skye District of the County Council, and was Medical Superintendent of the Martin Memorial Hospital, Uig. He identified himself with all matters likely to promote the welfare of the district. He was a member of the School Board for many years, was a Justice of the Peace for the County, and last year was appointed an honorary Sheriff-Substitute for the County, a unique honour for a medical man.

In the course of his professional career, Dr. Dewar had to deal with several serious outbreaks of typhus fever, notably one at Sconser, for the prompt and effective manner in which he stamped out that disease in the district he received the special thanks of the then Secretary for Scotland, Lord Balfour of Burleigh.

REGINALD R. WHISHAW, M.B., B.C. (ANTARCTIC).

F.R.C.S. (ENG.),
QUEENSLAND, AUSTRALIA.

LETTERS have arrived announcing the death of Dr. Reginald Robert Whishaw, formerly of Croydon, and more recently of Queensland, and the news will be heard with deep regret by his old friends in this country. Dr. Whishaw, on the completion of his general education, went to Cambridge, and after graduating B.A. turned to medicine, which he studied partly at Cambridge and partly at St. Thomas's Hospital. In 1885 he became M.R.C.S., L.R.C.P.; he graduated as M.B. in the following year, proceeding in 1888 to the Bachelorship in Surgery and the Fellowship of the Royal College of Surgeons. Meantime he filled the post of Demonstrator of Anatomy to the Bristol School of Medicine, having previously held a corresponding but junior appointment at Cambridge. He also held office as a resident at the Brompton Consumption Hospital and the Hospital for Children at Liverpool. Finally he settled down in practice at Croydon, where he was a member of the surgical staff of Croydon Hospital and carried on an extensive practice. After some years' successful work in this neighbourhood, however, the condition of his health became somewhat disquieting, and being advised to go abroad he chose Australia. In that country his constitution regained full strength, and he determined to remain there altogether. A year or two ago he became Assistant Medical Superintendent of the Hospital for the Insane at Willowburn, in Queensland, and it was to his connexion with this institution, and not to a recurrence of his original ill-health, that his death was due. During the performance of his duties a sudden attack was made upon him by a homicidal patient; the result was a fracture of the base of the skull, and death followed rapidly on December 10th, 1908. He had been sufficiently long in Australia for his excellent personal and professional qualities to have become widely known, and his untimely death at the age of 46 is a cause of general regret. Dr. Whishaw was twice married, and leaves a widow and four children.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL CHANGE OF ADDRESS.

THE offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL have been removed to 429, Strand.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Arctophila, London*. The telegraphic address of the MANAGER of the BRITISH MEDICAL JOURNAL is *Arctophila, London*.

TELEPHONE (National).—
EDITOR, GENERAL SECRETARY AND MANAGER,
2631, Gerrard. 2630, Gerrard.
MEDICAL SECRETARY, 2634, Gerrard.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Manager, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL NOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

1. We would request correspondents who desire to ask questions in this column not to make use of such signatures as "A Member," "A Member B.M.A.," "Enquirer," and so on. By attention to this request much confusion would be avoided. Correspondents are asked to write upon one side of the paper only.

C. D. desires advice as to the choice of a phonendoscope.

ANTIGUA desires to hear of a home where a woman, aged 46, suffering from paralysis agitans, would be taken; 10s. a week would be paid for her maintenance, and she is a very suitable case for charity.

B. B. W. desires to know the names and addresses of makers (not dealers) of the rubber portion of the ordinary nitrous oxide facepiece.

ANSWERS

ENQUIRER.—Permission to practise in the Principality of Monaco can, we believe, be obtained without serious difficulty by those holding British qualifications deemed equivalent to the French Diploma of Medicine. As such are at present regarded, the degree of Doctor of Medicine "of the University of the United Kingdom of Great Britain," and the Diplomas of Fellowship of the various Royal Colleges and of the Faculty of Physicians and Surgeons of Glasgow. Applicants have to undertake to practise in the Principality during the whole of the summer and autumn months, during which the place is hot and very empty, but fulfilment of this obligation is not always exacted. There are already five or six medical men holding British qualifications resident in the place, and last year among the British medical men, the vacancy thus created has, it is understood, been filled. Practically the only scope for practice is among the floating population of winter visitors.

DEFECTIVE CHILDREN.

IN reply to inquiries from two correspondents we would recommend in the case of an imbecile girl, aged 14, that application should be made to the Superintendent of the Magdalen Hospital for Imbeciles, Conde Down, Bath. In the case of a boy of the same age, the Royal Albert Asylum, Lancaster (Secretary, Mr. S. Keir), would seem to be a most convenient place. Failing that, application might be made to Mr. J. J. C. Turner, Secretary and Superintendent, Eastern Counties Asylum, Colchester, where the boy would probably be received on moderate payment.

In reply to another correspondent, who asks where a deaf and dumb boy could be taught to speak, we should recommend

application to Miss Hewitt, School for Oral Teaching of Deaf, Eaton Rise, Ealing, London, W., who would send particulars as to payment required by the society, etc.

FOLLICULAR STOMATITIS.

M. W. writes: In reply to Dr. R. M. Fraser's inquiry in the JOURNAL of January 9th, I beg to state that in the case referred to by me, vulcanite or india-rubber, either as dental plates or pessaries, have never been in use. The teeth are good, there is no complaint of indigestion, and the constitution is sound: the cause, therefore, must be looked for in some other direction.

LETTERS, NOTES, ETC.

ARSACETIN.

MESSRS. MEISTER, LUTETS, and BRUNING, Limited, have drawn our attention to the fact that in the note on their book on *Methods for Testing* published January 16th, page 195, the two last sentences were so placed as to confuse their meaning. These should have read: "The first item described is arsacetin, a drug favourably mentioned by Professor Neisser in his address on syphilis at the Annual Meeting of the British Medical Association at Sheffield. Chemically it is shown to be sodium p. acetyl-amino phenylarsine." They add that they will have much pleasure in supplying a copy of the book free of charge to any reader interested in its subject.

THE USE AND ABUSE OF THE CURETTE.

DR. ALEXANDER DUKE (London, W.) writes under date December 20th, 1908: The remarks made in the JOURNAL of December 19th, p. 1342, by Dr. Donald (Manchester) are much to the point. "We are all seeking after truth," and if any of us can "go one better" (even as regards our own results in restoration of health to suffering women) why should we not endeavour to do so? Following hard and fast lines never has led to much advance. We must leave the beaten track sometimes. Dr. Donald says, "The majority of the patients whose cases I have recorded sought advice on account of the intense pain at the onset of menstruation. The medical man who can diagnose the cause and give the most *lasting relief* surely should be entitled to the most credit." That the curette has been abused no man of any experience will deny, and Sir James Barr in his interesting paper on mitral stenosis very properly alludes to this abuse as practised on a patient suffering from "cardiac disease." I venture to say that a great number of cases treated by the usual routine of dilating and curetting would be much more benefited by uterine drainage (not by gauze, which only helps to dam up the secretions which as a rule are too viscid to permeate or escape through the gauze), but a proper-sized flexible tube (my intrauterine stem of spiral wire open from end to end and I have used for years past with good results, and if not effecting a cure, the curetting then, quite time enough to resort to. The uterus described by Bossi (small shaped) I imagine is produced by the continued spasmodic efforts of the body of uterus to force the secretions (normal or abnormal) through the obstructed cervix. I may be quite wrong, but reasoning from the cardiac hypertrophy so well known, I do not think my theory is so far out, more especially as by continued drainage and keeping cervical canal patent I have been able to find the uterus changing its shape and feel normal at least. It is quite obvious that a healthy uterus cannot become acutely flexed. Why not treat the flabby condition, and endeavour to restore muscular tone? Dilate if necessary. Drain, and by the rest afforded by the draining preventing spasm, and by allowing free exit of all secretions reserve the operation of curetting, etc., as a *demer ressort*.

"SUCH A SAVING."

(Overheard): Young mother (to a friend): "I went into hospital for my second. I was confined and churchered and baby was christened, vaccinated, and circumcised, all in a fortnight! Such a saving!"

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	0	4 0
Each additional line	0	6 6
A whole column	2	13 4
A page	8	0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

An Address

ON THE

PHYSIOLOGY AND PATHOLOGY OF
WORK IN COMPRESSED AIR.DELIVERED TO THE NEWCASTLE-UPON-TYNE CLINICAL
SOCIETY.

BY

SIR THOMAS OLIVER, M.D., LL.D., D.Sc., F.R.C.P.,

PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE.

My experience of compressed-air illness has been entirely gained during structural alterations on the Redhugh Bridge, the building of King Edward VII Bridge, and the tunnelling operations which are at present proceeding under the River Tyne between Wallsend and Hebburn. It took four years to build King Edward VII Bridge. In order to support the enormous weight which the bridge is obliged to carry, the piers had to be large, and as these had to rest upon a secure and solid foundation it was necessary to excavate the soil in the bed of the river to the depth of 70 ft. below high-water level mark. In their excavations the workmen passed through strata of silt, gravel, clay, soft coal, etc. The caissons successively in use were large, as may be inferred from the fact that thirty-five men worked in each caisson at one time. The working chambers measured 113 ft. in length, 35 ft. in width, and 9 ft. 6 in. in height, and had a cubic capacity of 23,142 ft. The total number of men employed in caisson work was 150, and the total number of days spent in this kind of work was 267; 48 men worked under air pressure through the three caissons from start to finish without being affected; 29 men worked through two caissons, or 180 days, and remained in good health; and 49 men through one caisson, or 90 days, without symptoms. No man over 40 years of age was allowed to work in compressed air; 4 per cent. of the men applying for work were rejected at the primary medical examination, while 31 men, partly through fear and partly through muscular pains, gave up their employment within a fortnight. The largest number of cases of compressed-air illness occurred when the pressure employed varied between 24 and 32 lb., and principally during the months of September and October. No case occurred under 20 lb. pressure, but there was one case of "bends" at 22 lb. pressure. The largest number of men employed in building the bridge in any day was 750.

A caisson when in position is in its simplest form an iron cylinder, somewhat bell-shaped at its lower extremity, and closed at its upper by a sliding door which forms the ceiling of the chamber wherein the men work, and which separates it from the material lock or the chamber through which the buckets filled with soil escape through the sliding doors that constitute the roof of the caisson. Leading out of the upper part of the caisson at its side, just underneath the ceiling referred to, is an iron door which, when open, allows of entrance into a smaller chamber called the "air lock," and through which the men gain entrance into and emerge from the working chamber proper. If a caisson is large it may have two or three shafts or cylinders leading into it. It is not necessary to have the material lock on the same cylinder as the air lock. In Amsterdam I found the soil was removed through a material lock on a different shaft to that by which the men entered and left the working chamber. This is known as the Zschokké lock, and is worked automatically. On the Tyne all the caissons had three shafts, each with its own air and material locks. When placed in position on the bed of a river, a caisson, being a pneumatic chamber, would swim were it not for the large amount of concrete superimposed upon it. Air under pressure is pumped into the chamber to keep the water out and to allow the men to work therein. The surplus air escapes by the cutting edge of the bell-shaped expansion, and by this means ventilation is secured. In making tunnels the caissons are constructed in rather a different manner, since the line of procedure is not vertical but horizontal. Caissons have to be strongly built so as to withstand enormous air pressures. When the necessary depth has been attained

and further sinking is unnecessary, the caissons are filled internally with concrete, and they thus become the foundations upon which the piers of a bridge are built and the superstructure reared.

COMPRESSION AND DECOMPRESSION.

When men are passing into compressed air for the first time they often experience unpleasant sensations. Many become nervous, and they are conscious of their heart beating a little more quickly. Others, again, experience a considerable amount of discomfort which gradually increases to severe pain in the ears owing to the membrum tympani being forcibly driven inwards. This occurs when there is a deficiency of air in the middle ear either as the result of the Eustachian tube not being patent enough or as a consequence of naso-pharyngeal catarrh. The tympanum has been known to rupture, and as the blood vessels in the middle ear are dilated hæmorrhage has occurred, leaving a temporary or permanent injury behind in the organ of hearing. Workmen who are in the habit of passing through the air locks can, by a peculiar method of swallowing, carry air up the Eustachian tube, and by thus equalizing the pressure on either side of the tympanum escape the pain and unpleasant sensations which are experienced by the men who are new to the work. In my experiments upon animals, although most of them seemed to bear rapid compression quite well and to be uninfluenced by it, others would fall upon their side and become convulsed—symptoms which disappeared as the pressure went on rising, and from which they entirely recovered by remaining in the compressed air. Since it is the men who are about to work in compressed air for the first time who are most likely to suffer pain and discomfort in the ears, and there will always be some men who will never be able to bear compressed air well, there ought to be some means inside the air lock whereby those inside can communicate with the man in charge of the pipes outside, so that the pressure may be reduced on the supervision of symptoms, since these may become almost unbearable and if not relieved might lead to serious harm, although in my own experiments animals that were convulsed improved with a rising pressure. It is well to raise the pressure slowly, for by this means the men become accustomed to the changing conditions and they are less likely to suffer in the manner indicated.

When the pressure inside the air lock has come to equal that inside the cylinder the inner door is pushed open, and the men pass into the caisson and descend the ladder to the bottom of the shaft. Here they work for a few hours. Since it is necessary that the air inside the caisson shall be kept as pure as possible, an excess of air must be pumped in, and care must be taken that it is not fouled by the products of combustion of naked lights. The electric light is preferable to lamps and candles. The surplus of air escapes by the free edges of the caisson. Free ventilation keeps the air in the interior of the caisson cool. As there is a danger of the air coming from the compressor engine becoming too hot, the cylinder should be covered by a water jacket in which cold water is kept circulating. It is most unusual for men to become ill when working inside a caisson; most fortunately, too, very few accidents occur inside.

After three or four hours' work the men leave the caisson, and in passing out through the air lock they undergo what is called "decompression." It is occasionally during, but mostly after, decompression that symptoms of compressed-air illness show themselves. Having entered the air lock and closed behind them the door leading into the caisson, the pressure in the air lock is for a brief period the same as that under which they have been working; but, by opening a valve on the outside of the air lock, the man in charge allows air to escape into the external atmosphere, and, when the pressure inside the air lock has come to equal that of the external air, the door can readily be opened, and the men emerge enveloped in a thick cloud of white mist.

LENGTH OF SHIFT.

The length of time spent by the men in the working chamber should be inversely proportional to the pressure. As excavation of the bed of a river proceeds and the caisson sinks, the pressure inside has to be correspondingly raised, and the duration of the working period neces-

sarily shortened. At King Edward VII Bridge there were two shifts—one for the day and another for the night. When the pressure was 25 lb. the men worked ten and a quarter hours, namely:

6 a.m. to 8.30 a.m.	2½ hours
9.15 a.m. to 1 p.m.	3¾ "
2 p.m. to 6 p.m.	4 "
			10½ "

But as the caisson sank and the pressure rose to 35 lb. the number of hours worked a day was shortened. Four hours was the longest time spent in a caisson, and the greatest depth attained was 70 ft. below high-water level mark. On tidal rivers the pressure keeps rising and falling with the tide. In some of the American tunnels the men were allowed to work only one hour at a stretch when the pressure was 50 lb. In Amsterdam I found the men working at a depth of 66 ft. below the surface, and under a pressure of 30 lb. These men worked four hours at a stretch, came out for eight hours, and returned to work for another four hours, making an eight-hour day. Although in Holland the intervals between the shifts were unusually long compared with those on the river Tyne, there were just as many cases of the minor forms of compressed-air illness among the Dutchmen as among the men on the Tyne.

Although one of my patients became ill in the air lock when undergoing decompression, it is generally after the men come out of the air lock that symptoms develop. As a rule the men come out feeling quite well. It may be before they leave the works, when they are proceeding homewards, have reached home and gone to bed, or are partaking of a meal, that the men all at once complain of severe pains in their limbs or abdomen. Some are sick and vomit, others become dizzy and in trying to walk fall owing to sudden loss of power in their lower extremities; others, again, have a bleeding from the nose or mouth, or are the subjects of a degree of nervousness often amounting to terror. In the worst forms there is unconsciousness.

Occasionally the symptoms resemble hysteria, or there is intense excitement, which goes on to frenzy. The most common symptoms are muscular pains, known as "bends," or there is loss of power in the lower extremities, attended by retention of urine, and requiring the use of the catheter. Fortunately in most instances the paralysis of the limbs passes away in a few days, but occasionally it lasts for months, with all the physical signs of a limited myelitis. In one of my own cases the paralysis, which was accompanied by loss of sensation, became permanent, bedsores formed, and the patient succumbed to septicaemia and tuberculosis.

CAUSE OF THE SYMPTOMS.

Men inside a caisson are working under abnormal conditions. They are under a higher atmospheric pressure than when at the surface. The work, too, is hard, since it is all manual labour, hence the necessity of pumping into the caisson a superabundance of air drawn from an uncontaminated source. Although the air supplied may be pure, it may become fouled inside the caisson by gases evolved from the strata during the process of excavation. It was when passing through a thin stratum of soft, mushy coal on the river Tyne that unpleasant odours were complained of by the men, and several of them became ill. At this particular time the men were not working under high atmospheric pressure, so that probably the air had become impure by H₂S or CO, and this circumstance contributed to their becoming ill. High pressure, while an important factor in caisson disease, is not the only factor. At Greenwich, for example, out of 9 cases of compressed-air illness, 3 occurred in men who were working in a pressure of only 12 lb., and at the Blackwall Tunnel men also became ill under remarkably low pressures. The worst and only fatal case which I had was that of a man who had been in a pressure of 25 lb. for four and a half hours, and who was decompressed in three minutes. The length of exposure to the pressure and the purity of the air breathed have to be considered as well as the amount of pressure. Although opinions differ, yet the influence of the purity of the air breathed cannot be altogether ignored when viewed in the light of Snell's experience at the Blackwall Tunnel. When the amount of air supplied was 4,000 cub. ft. per man

per hour, there were 28 cases of compressed-air illness in 100 days, but when 12,000 cub. ft. of air were supplied the cases fell to zero. Copperthwaite maintains that the number of cases of compressed-air illness is proportional to the amount of carbonic acid in the air breathed, and that when the CO₂ reaches 1 per cent. illness may be expected. Although the greater the amount of air supplied per man the less likely it is to contain impurities, yet at the Brooklyn Bridge, New York, while 1,400 cub. ft. were supplied per man per hour, the air in the caissons frequently contained 0.3 per cent. of CO₂. On the river Tyne 1,320 cub. ft. of air were supplied, and the average amount of CO₂ present was 0.2 per cent.

The larger the number of men working in a caisson the greater should be the amount of air introduced in a given time. Now and again it happens that a caisson suddenly sinks on to a clay bed and the surplus air can no longer escape as heretofore by the free edge of the caisson. As air under compression is still being pumped into the caisson, this chamber would probably rupture were it not for the fact that both at the upper part of the shaft and on the compressor engine itself there are safety valves which act automatically when the pressure inside the caisson reaches a little higher than the maximum pressure the men have been working at on any particular day. In tunnelling operations, where the line of procedure is not vertical but horizontal, when gravel is reached there is often a very free escape of air, so that in order to keep up the pressure enormous quantities of air have to be pumped in—say 4,000 to 8,000 cub. ft. per hour—a large amount compared with the 1,320 on the river Tyne, but yet small when compared with 15,000 cub. ft. occasionally required at the Baker Street and Waterloo Tunnel. At the Baker Street Tunnel sometimes the amounts of air sent in were 1,300 and 2,000 cub. ft., and it is interesting to know that when the freest ventilation prevailed there were only eight cases of compressed-air illness in one month, and when the worst conditions prevailed there were thirteen cases in twelve days. In passing through the clay soil the amount of CO₂ in the London tunnels frequently rose to 0.1 per cent., whereas with a gravel face the percentage varied between 0.05 and 0.07. In making the Hudson Tunnel, New York, the CO₂ occasionally rose to 2 per cent., or 20 parts per 1,000 of air, and the men died at the rate of 25 per cent. per annum. Although at first sight it would appear as if at the Hudson Tunnel the large percentage of illness was due to the amount of CO₂ present in the air, yet it cannot be said that CO₂ is the cause of compressed-air illness, since in London it was found that it was not when the men were working at a clay face and the percentage of CO₂ highest that the amount of sickness was always greatest; nor on the river Tyne did there appear to be any close relation between the amount of sickness and CO₂ in the air.

In all industrial occupations experience has shown that the freer the air is from CO₂ the larger is the amount of work done by the men and the less is their sense of fatigue. Opinions differ as to the harmful effects of this gas upon workmen. At the Brooklyn Bridge the men suffered when the CO₂ in the air reached 0.3 per cent., and Copperthwaite tells us that when the CO₂ rises to 1 per cent. illness may be expected. Owing to the comparatively small size of my compressed-air chamber I have not had the opportunity of trying experiments upon animals larger than dogs. I have, however, been struck by the results obtained when mice, rats, and dogs have been exposed to varying percentages of carbonic acid and carbon monoxide. According to Copperthwaite, 1 per cent. of CO₂ is regarded as dangerous, and yet I have exposed a dog for two hours under a pressure of 25 lb. in an atmosphere containing 3.4 per cent. of CO₂ and 0.6 per cent. of CO and decompressed the animal in thirty-five seconds without the slightest harm resulting; also to 3 per cent. of CO₂ for two hours and decompressed in twenty-five seconds, and yet the animal suffered no inconvenience. The same dog was in compressed air containing 2.26 per cent. of CO₂ for seven hours and under 50 lb. pressure, and developed no symptoms after decompression, while a rat, after exposure to 0.62 per cent. of CO₂ atmosphere for seven hours under 50 lb. pressure and gradually decompressed, was found dead on the following day.

Carbon monoxide is a deadly poison, and yet by degrees animals seem to become acclimatized to it. I got a dog to

become capable of breathing under 50 lb. pressure an atmosphere containing 0.3, 0.4, 0.57, 0.8, 0.95, and 1.6 per centages of CO for from eight hours with the smaller quantities to two hours with the larger percentages, and to be decompressed in the last instance in three-quarters of a minute without suffering. The question of the acclimatization of man and animals to CO is very important from the point of view of the work of the coal miner and rescue work after colliery explosions.

Sulphuretted hydrogen is also a very poisonous gas, but I found that traces could be borne for four hours—for example, 0.005 per cent. for one hour, 0.019, and 0.02 also for one hour without any mishap, but that 0.2 per cent. was fatal.*

Without oxygen mammalian life cannot be maintained, and yet under certain circumstances oxygen is a poison. The exposure of animals to high atmospheric pressures of oxygen is dangerous. In exposing mice to 10 atmospheres of oxygen the breathing after a short time becomes rapid, the animals become comatose, and they die in convulsions before decompression is effected. Now, since animals exposed to the same pressure of ordinary atmospheric air did not exhibit in the caisson any symptoms at all, the presumption naturally is that the oxygen acted as a poison. Exposures of animals to high pressures of ordinary atmospheric air and to oxygen are therefore not the same. Oxygen is a protoplasmic poison; it lessens respiratory exchange and induces convulsions. Professor Lorrain Smith of Manchester University found that "exposure of animals to a tension of 170 to 180 per cent. atmosphere of oxygen causes in a short time diminution in the power of the lungs to absorb oxygen actively, and that with a continuance of the exposure the arterial oxygen falls till it reaches the level for which mere diffusion of oxygen from the alveolar air might account." This effect is largely due to the fact that oxygen has an irritating effect upon the lungs, and produces first congestion of these organs, and subsequently haemorrhagic consolidation of them. The lungs become hepatized as in pneumonia. Finding that very high pressures of oxygen atmospheres caused death by inducing pneumonia, Lorrain Smith is of the opinion that inflammation of the lungs is a cause of caisson disease; but, as we have already seen, this can scarcely be the cause, for the symptoms of compressed-air illness are not on the side of the respiratory organs, but in the neuro-muscular system.

PHYSIOLOGY OF CAISSON WORK.

When a gas and a liquid are brought into contact with each other the liquid takes up the gas in solution, and this absorption will continue until the liquid saturated with gas ceases to take up more. No chemical compound is necessarily formed as a consequence of this union. The amount of gas in solution depends upon the solubility of the gas, the temperature of the liquid, and the amount of pressure. The amount absorbed varies directly with the pressure in accordance with Dalton's law. When men are working in compressed air their blood will take up a larger amount of nitrogen and of oxygen in simple solution than at atmospheric pressure. Since the oxygen of the inspired air mostly enters into loose chemical combination with the haemoglobin of the blood corpuscles there will be only a small amount of oxygen taken up by the liquid part of the blood, and what is taken up will probably quickly disappear in the tissues. The amount of carbonic acid normally present in the alveolar air of the lungs at ordinary pressure is about 5.6 per cent. Dr. John Haldane, whose work on this subject is of the greatest value, maintains that in a caisson the "compressed air makes no difference as regards the solution of CO₂ in the blood, since, unless the air breathed is foul, the presence of CO₂ in the lung air is kept constant by the breathing, whatever the total atmospheric pressure may be"—that is to say, that any slight excess of CO₂ will stimulate the respiratory centre, quicken and deepen the breathing, and thus get rid of the excess of CO₂. Experience, on the other hand, shows us that asphyxia by CO₂ does occur, either by accumulation of CO₂ in the blood or through a deficiency of oxygen. It is different with nitrogen, which forms 79 per cent. of ordinary atmospheric air. This gas does not enter into chemical combination with the blood.

In compressed air larger quantities are taken up by the liquor sanguinis; and, as the nitrogen-saturated blood circulates through the body, the tissues in time also become saturated with the gas. Each time the right ventricle contracts, the blood which is sent to the lungs becomes saturated to the same pressure of nitrogen as that of the nitrogen in the alveolar air. The arterial blood will part with this nitrogen to the tissues, so that the venous blood returning to the right side of the heart will contain less nitrogen, and be again ready to take up more gas in passing through the lungs, but the amount of nitrogen taken up will gradually get less and less with each systole as saturation takes place and the pressure of nitrogen in the blood and tissues becomes equal to that in the alveolar air.

Haldane has given a vivid description of the saturation of the blood and tissues by nitrogen. The gas in solution in the blood exerts the same pressure as that exerted by the gas in contact with the blood; and when the external pressure falls, as during and after the decompression of a workman in the air lock, the gas in solution again assumes the gaseous state, and appears in the form of bubbles in the blood and tissues. The parts of the body which have a rapid circulation become more rapidly saturated than those with a feeble circulation, and as they become more quickly saturated they will also the more quickly desaturate. It has been known for long that stout men do not bear work in compressed air well. The explanation is apparent. Mr. Ramsbottom—my former colleague in the physiological laboratory—and myself found that fat absorbed under pressure a large quantity of air. The fat of the human body is capable of obtaining a much larger quantity of nitrogen than blood, hence the role attributed to obesity in the compressed-air illness of caissoniers. Even admitting this, there is probably involved in the circumstance more than the question of fat.

At King Edward VII Bridge the men worked in pressures up to 35 lb., but in some places work has been done in 67 lb. pressure, equivalent to 4.45 atmospheres. Experimentally higher pressures have been borne. Leonard Hill exposed himself to a pressure of 75 lb., and Greenwood to 92 lb. Greenwood was in the compressed-air chamber for fifty-four minutes, and although two hours seventeen minutes were spent in decompression he experienced severe pains twenty minutes after leaving the compressed-air chamber. Paul Bert exposed dogs to 10 atmospheres of ordinary air for a lengthened period and decompressed them slowly without any bad effects.

In the discussion which followed the reading of my paper on the Use of Caissons in Bridge Building, at the Society of Arts, May 11th, 1906, Mr. E. W. Moir, of Messrs. Pearson and Son, contractors for the Admiralty Pier at Dover, the Hudson Tunnel, New York, and other large engineering undertakings, gave interesting data in regard to the length of time animals could remain under high pressure without any bad effects. At the old Hudson Tunnel the mules remained underground under pressure for twelve months. All that time they appeared to be quite comfortable; they were frisky, and they worked eight-hour shifts. After being in compressed air for over a year, the contractors, wishing to bring them to the surface, gave each of the mules a bottle of whisky and applied mustard jackets over such parts of their bodies as they thought might possibly become affected. The mules were brought out very slowly, half a day being spent in decompression. The animals were no worse for their long immersion, for when sold they realized excellent prices.

PATHOLOGY OF CAISSON DISEASE.

Two years ago Dr. Parkin, Assistant Physician Royal Victoria Infirmary, and myself carried out a series of experiments upon pithed frogs in compressed air. I gladly take this opportunity of publicly expressing to Dr. Parkin my sense of indebtedness for the generous help he then rendered me, and of the assistance I have received from his thesis on Compressed Air. We subjected frogs to extremely high pressures, and after a time suddenly decompressed some of them. The web of a frog's foot was drawn over the inside of the glass window of the compressed-air chamber, and by means of the microscope and electric light illumination we could watch the circulation of the blood in the frog's capillaries. During compression the circulation proceeded

* For assistance in the gas analyses I am indebted to my colleague in the Physiological Laboratory, Mr. Frank Howson, M.A.

quite naturally, but after sudden decompression, while the circulation seemed to go on apparently unchanged, by degrees the rate of the blood flow diminished, and gradually ceased, preceded by a slight to-and-fro movement. All at once a bubble or two of air would appear in the capillaries, and these running together formed a large embolus inside the vessel. Occasionally air bubbles appeared in the tissues external to the blood vessels, and were due sometimes to rupture of the capillaries or to desaturation of the tissues. It is the presence of gaseous emboli in blood vessels, the accompanying stagnation of the circulation, and the occasional rupture of small blood vessels with hæmorrhage which are the pathological lesions present in most cases of compressed-air illness. It is the bubbles of nitrogen gas in the small blood vessels of the brain and medulla and the presence of air spaces in the cerebral tissue which explain the sudden death of divers and caisson workers after decompression: also the presence of similar lesions in the lower part of the spinal cord which explains the paralysis of the lower limbs, and when present in the muscles and around the joints, the severe pains known as "bends." In opening the bodies of frogs, mice, and rats which had died shortly after decompression, bubbles of air can be seen escaping from the heart when that organ is cut into, also from the liver and the subcutaneous tissues. The bubbling of gas in the blood and tissues of the body after sudden decompression is aptly compared with the effervescence which occurs in a bottle of soda water on removal of the cork, and, in a word, is the pathology of caisson disease.

Apart from the dangers incidental to rapid decompression, caisson workers are exposed to other risks—for example, (a) accidents occurring inside the caisson during the ordinary work therein: fortunately such accidents are extremely rare; (b) the breathing of an atmosphere polluted by CO_2 , CO or H_2S ; (c) sudden inrush of water into a caisson, owing to an untimely manipulation of the doors of the locks; and (d) sudden rupture of a caisson.

The first two of these risks have been already dealt with, but the possibility of a sudden inrush of water calls for a few remarks. During the building of a pier at Havre in September, 1905, one door leading into a caisson was opened at the wrong time. As a result of the sudden fall of pressure, water rushed into the caisson and drowned one of the workmen. The other men only escaped with difficulty. The possibility of an accident such as this can only be obviated by having competent and reliable men in charge of the locks.

Another danger is sudden rupture or explosion of a caisson. This occurred a few months ago at Hebburn, where, after the men had been working for nearly two hours in a pressure of 30 lb., the caisson suddenly burst. The four men inside were immediately decompressed; one man who was at the bottom of the shaft was killed by falling timber, broken iron plates and debris, but the other three, although injured about the head and limbs, in no way suffered as a consequence of the immediate decompression. The accident occurred about the breakfast hour. In conjunction with Dr. Macley, of Wallsend, I visited the scene of the explosion in the afternoon. On the following day, along with Dr. Inglis, of Hebburn, I visited the injured men in the Hebburn Infirmary, but although all were bruised, as the result of the physical injuries they received, not one of the men, either then or subsequently, was anything the worse for the instantaneous decompression. It might be argued that the length of time spent by the men that morning in the caisson was too short for a considerable amount of gas to have passed into solution in their tissues; but although the figures given are approximate, Haldane states that in one hour the various parts of the body became saturated with nitrogen to the extent of 70 per cent., and in two hours to 92 per cent. The fact remains that three men were instantaneously decompressed, and not one of them developed symptoms of compressed-air illness. It is difficult to say why no serious symptoms followed.

PREVENTION.

Believing that the cause of caisson disease is the liberation of bubbles of gas in the blood vessels and in the tissues, and that slow decompression by giving time allows the dissolved nitrogen to gradually escape through the vessels of the lungs into the alveolar air, physiologists have recommended that decompression should be slowly per-

formed; also that the time spent in the act should be directly proportional to the amount of pressure and the length of exposure to it. Compression also should not be quickly hurried over. One minute for every 5 lb. of pressure, or three minutes for each atmosphere, formed the minimum time spent in the air locks at the King Edward VII Bridge for decompression—a short time compared with the forty minutes required of the workmen in Amsterdam exposed to only 2 atmospheres of pressure. Hill and Macleod recommend when men have been exposed to 2 atmospheres, or 30 lb. pressure, thirty minutes to one hour to be spent in decompression, and for 3 to 4 atmospheres—that is, 45 to 60 lb. pressure—one to two hours for decompression. My feeling is that it would be almost impossible to get the British workman to submit to spending this length of time in decompression, and no wonder, for during decompression the temperature inside the air lock falls several degrees, and the men, perspiring and fatigued with their work, are apt to become chilled unless they have been supplied with blanket rugs. Besides, it is well known that the workmen prefer to run all sorts of risks than endure the ennui of slow decompression. Some boast of having come regularly out of the caisson through the mud lock, quickly decompressed, without experiencing the slightest inconvenience, but this circumstance must not be taken as a recommendation for the adoption of a procedure which both experience and experiment show to be extremely dangerous.

The irksomeness of slow decompression can, to some extent, be overcome by "stage" decompression on the lines indicated by Haldane. He recommends as being within the limits of safety rapid decompression from a high to a moderate pressure, and this to be followed by slow decompression for the remainder of the pressure. It is possible to decompress from 6 to 3 atmospheres, from 4 to 2 atmospheres, or from 2 to 1 suddenly, and then to decompress slowly during the remainder. "The danger of rapid decompression," Haldane says, "depends not on the absolute difference between the initial and final pressures but on the proportion between the two pressures. If this proportion is only 2 or 2.3 to 1 the decompression is safe; if, on the other hand, the proportion is 3 or 4 to 1 the decompression is dangerous." It is towards the end and not in the early stages of decompression that the danger reaches its maximum, hence the pressure may be suddenly reduced one-half provided the remainder of the decompression is slow. This method of decompression would certainly expedite the transmission of the men through the air lock and would shorten the time spent in decompression.

If there is one occupation which should be followed only by comparatively young men, and one in regard to which previous medical examination of the workman is necessary, it is work in compressed air. In medicine it frequently happens that experience is in advance of explanation. It has been known that the men who suffer least are those who are aged between 20 and 30 years of age, who are temperate and of spare build, and whose tissues are still elastic. Stout, flabby men do not bear caisson work well, the reason being, as Vernon found, that fat not only takes up six times more nitrogen than most of the other tissues and fluids of the body, but it saturates and desaturates more slowly. As already stated, it remains to be shown that slow desaturation is a disadvantage.

TREATMENT.

Since compressed-air illness is due to the presence of bubbles of air in the blood and tissues, both Mr. W. E. Moir of Messrs. Pearson and Son, and Dr. Andrew Smith of New York suggested that on the appearance of symptoms the workman should be placed in an air lock and again compressed. It has been shown experimentally that during recompression the bubbles of air disappear, and that if the second decompression be slowly effected the symptoms may not reappear. Recompression must certainly give rapid relief to the "bends" or muscular pains complained of by the men. There should be no large working in compressed air undertaken without there being close at hand a medical air lock large enough for one or two men to lie down in, suitably heated and lighted. I can bear testimony to the efficacy of recompression even in cases where minor degrees of muscular paralysis had appeared. At the Hudson Tunnel it was found that, after the introduction of

the recompression chamber, the death rate among the workmen fell from 25 to 14 per cent. per annum. To get the best results the men should be placed in the immersion chamber as early as possible after the development of symptoms. In many instances symptoms do not recur after recompression; in other instances relief may or may not be obtained. The following is an interesting experience of recompression given to me by a patient under my care in the Royal Victoria Infirmary:

On August 6th, 1908, a sinker, aged 25, went to work at 6 a.m., and remained under 30 lb. pressure until 9 a.m. After coming out of the air lock he felt pains in his back and fainted; he was carried into the medical lock and recompressed in a pressure of 20 lb. At 10 a.m. he had recovered, and preferred to go back to work in the caisson, where he remained until 12 p.m. feeling quite well and doing his work as well as the other men. He had hardly left the air lock a second time when he was seized with pains in his arms and elbows, and was placed in the recompression chamber. After being there for half an hour and feeling relieved, the pressure was lowered to 24 lb., but as the pains returned the pressure was again raised, and he remained in the chamber until 6.15 p.m., when he came out free from pain. He left the works and was proceeding homewards, when he was seized with pains in the right arm; but he went home, had tea, went out for a short walk, and afterwards went to bed. The pains by this time had become so severe that he could not sleep. He got up, and going back to the works he re-entered the medical lock at 10 p.m., where he stayed until 5 a.m. on August 7th. He slept for four hours in the medical lock, and on coming out was all right, but severe pains developing in his knee. He again entered the medical lock at 5.45 a.m. and stayed there until 8.45 a.m. in a pressure of 25 lb. Shortly after leaving the recompression chamber the pains returned, and as these were severe Dr. Macley gave him a hypodermic injection of morphine and sent him into the Newcastle Infirmary. The patient, who was a well-developed man, had previously worked under 25 lb. pressures in Dublin for six months, and in Glasgow for four months under lower pressures, without suffering. When admitted into the infirmary he was still in such pain in the knees and elbows that he had to have another injection of morphine. There could be felt distinct creaking in the skin over the left knee as in emphysema. By degrees the pains lessened and ultimately disappeared. The temperatures for the three evenings after his admission were 100°, 100.4°, and 99.80° F. The sounds of the heart, which were normal, were distant and not at all easily heard.

When recompression cannot be carried out, as, for example, when the symptoms come on long after a man has left the works, he should be put to bed, kept warm, and if in great pain a hypodermic injection of morphine may be administered. In many of these cases, even although there is no paralysis of the limbs, there is frequently a paralytic condition of the bladder attended by retention of urine, and calling for the use of the catheter. Muscular paralysis, loss of sensation, bedsores, and complications must be treated on ordinary lines.

Since the risks to life from rupture of a caisson are enormous, the greatest care should be taken to prevent such an accident. Whether the shifting of the surface of the river's bank towards the Tyne at Hebburn on account of the excessive dredging of the river so pressed upon the caisson and cracked it, or whether there had occurred a sudden lowering of pressure followed by a jerk of the caisson which broke its attachments, it is difficult to say, but engineers are agreed that caissons should be made of strong steel or of wrought iron plates, and not of cast iron, and that these chambers should be made of such strength as to bear two or three times greater pressure than is ever likely to be required of them.

THE Belgian Minister for the Colonies has ordered the establishment in the Congo territory of six new lazarettos for patients suffering from sleeping sickness. The lazarettos will be under the charge of Belgian doctors.

THE Local Government Board in England has issued to port sanitary authorities, and certain other sanitary authorities, a circular (Foreign Meat, No. 3), stating that there has been published in the *London Gazette* of January 22nd a notice containing a schedule of labels and marks declared to be admissible as official certificates in respect of foreign meat which consists of pork, or other edible parts of the pig, which has been subjected to inspection in Denmark, the Netherlands, the Dominion of Canada, and the Dominion of New Zealand. Attached to the circular are facsimiles of the marks. The fact that such a label is attached to the carcasses of pigs or any other kind of imported pork does not exempt the meat from liability to examination.

A Lecture

ON THE

USES OF THE CALCIUM SALTS IN VARIOUS MORBID CONDITIONS.

DELIVERED AT THE MEDICAL GRADUATES' COLLEGE AND
POLYCLINIC, NOVEMBER, 1908.

By ARTHUR P. LUFF, M.D., B.Sc., F.R.C.P. LOND.,

PHYSICIAN TO ST. MARY'S HOSPITAL.

In 1898 Sir Almroth Wright pointed out that conditions of deficient blood coagulability do not always manifest themselves in a tendency to actual hæmorrhages, but also manifest themselves in a tendency to increased transudation of plasma through the capillary wall—that is, in a tendency to “serous hæmorrhages.” He pointed out that this condition of serous hæmorrhage can to a large extent be controlled by increasing the coagulability of the blood by the administration of a calcium salt. Examples of such serous hæmorrhages are urticaria, chilblains, oedema of the feet and hands not due to heart disease, kidney disease, or venous obstruction, and a certain form of headache known as the “lymphatic type of headache.” Chilblains are always associated with a condition of defective blood coagulability, and the condition is also fairly frequently associated with the liability to attacks of urticaria and epistaxis.

LYMPHATIC TYPE OF HEADACHE.

This type occurs more frequently in women than in men, and generally manifests itself as a dull heavy ache in the frontal region, or occasionally as a throbbing pain in the frontal and temporal regions. In a few cases it may occur in any part of the head. It is generally experienced on waking in the morning, and usually diminishes in intensity or disappears after a few hours. It is most intractable to the ordinary methods of treatment for headache, and may persist for years unless the association of it with a lowered coagulability of the blood is recognized and suitable treatment for that condition employed. The subjects of this form of headache are usually of the lymphatic type, with a tendency to slight oedema of the face, eyelids, hands, and feet. There is generally some anaemia and a varying amount of lassitude, both physical and mental.

G. W. Ross was, I believe, the first to suggest that serous hæmorrhage might be the basis of these headaches, and he demonstrated that in 10 cases of lymphatic headache which were definitely shown to have a lowered coagulability of the blood, the administration of a calcium salt was in every case followed by the exaltation of the coagulability of the blood, and concomitantly with or closely following upon this alteration in the blood the headaches were relieved. He also showed that decalcification of the blood by the administration of potassium citrate, with the consequent diminution of the coagulability of the blood, caused a reappearance of the headaches.

During the past nine years I have treated a large number of cases of deficient blood coagulability in both private and hospital practice, with remarkably successful results in the majority of cases. I propose in this communication only to deal with those cases (121 in all) in which I am able to record the results of the treatment after the lapse of prolonged periods from the initial course of treatment. In no single case amongst those recorded in this paper has this period of observation been less than one year, and in several of them it has extended over from one to eight years. The results, therefore, show whether the improvement is a lasting one or not.

With the exception of the 5 cases of aneurysm, which were treated in hospital practice, all the cases were treated in private practice, as I found that in such cases I was better able to follow up the results of the treatment, either from the patients themselves or from their medical attendants, than in the cases of hospital patients. In several of the cases the diminished coagulability of the

blood was experimentally determined before the commencement of treatment; in others it was inferred from the symptoms and history.

METHOD OF TREATMENT.

The calcium salt that I have used in all the cases was calcium lactate, as that salt possesses many advantages over calcium chloride. Calcium lactate has scarcely any taste, and is practically devoid of irritant properties, whereas calcium chloride is an irritant to the stomach, and possesses a most unpleasant taste. The lactate is sufficiently soluble in water (1 in 15), and the organic lactic acid moiety of the salt is readily oxidized in the system, with the result that the base is placed more fully at the disposal of the organism than in the case of the mineral acid salt. In other words, calcium lactate is more readily absorbed into the blood than is calcium chloride. It is important that the lactate should be fresh as it decomposes after long keeping. The indication of its freshness is that it should form a clear solution in water, or at least that the solution should only be faintly turbid. Any definite white precipitate in its solution is an indication that the salt has undergone some change, and that therefore in that state it should not be employed.

For adults the dose given in all the cases was 15 grains of the calcium lactate dissolved in a fluid ounce of chloroform water, with the addition of a half to one minim of tincture of capsicum. This dose was always ordered to be taken three times a day, and one hour before meals. I consider that the administration of the medicine about one hour before meals is an important point, as it allows absorption of the salt to take place prior to the introduction of food into the stomach, and so the precipitation of the calcium by the phosphates and possibly other constituents of the food is prevented. The calcium lactate was in all the cases given over a period of six weeks. Constipation is a common accompaniment of the administration of the calcium salt, and must be controlled. For this purpose it is not desirable to give saline purgatives, owing to their precipitant action on calcium salts. The laxative that I have found most useful in such cases is an infusion of senna pods, which should be taken at bedtime.

In a small proportion of the cases described as cured a few slight relapses occurred, generally some months after the course of treatment, but these were in all cases speedily relieved by the readministration of the calcium lactate for a short period (generally from one to two weeks).

THE VARIOUS CONDITIONS TREATED AND THE RESULTS OF THE TREATMENT.

Headache.—These cases were all of the lymphatic type, and were associated with slight oedema of the feet and hands, and generally of the face and eyelids. The records of 45 cases are known. Of these, 37 (82 per cent.) were cured, 2 were considerably benefited, 2 were slightly benefited, and in 4 cases (9 per cent.) no good resulted. The headache was generally relieved in from one to three days. These headaches were always associated with lassitude, and in all the cases successfully treated there was a remarkable improvement in physical and mental tone. In cases of headaches not of the lymphatic type the treatment with calcium lactate is not of the slightest use.

Chilblains.—All the cases were associated with cold hands and feet, and with some oedema of the hands and feet, which was generally slight in amount. The records of 37 cases are known. Of these, 29 (78 per cent.) were cured, 1 was considerably benefited, 3 were slightly benefited, and in 4 cases (11 per cent.) no good resulted. In several of the cases recorded as cured slight relapses occurred, generally in the following winter, but they all rapidly responded to another course of treatment with calcium lactate of usually two to four weeks' duration.

Boils.—All the cases were associated with cold hands and feet, and with slight oedema of the hands and feet. The records of 8 cases are known. All were cured, and up to the present time no relapses have occurred.

Urticaria.—Seven cases of severe urticaria associated with coldness of the extremities and oedema of the hands and feet were treated. None of them were cases of urticaria due to food. Six were cured, and in one case no good resulted.

Flushing of the Face.—These cases were associated with coldness of the extremities, and generally with cardiac palpitation. The records of 6 cases are known. Four were cured, and in 2 cases no good resulted.

Aneurysm.—Five cases of aneurysm of the arch of the aorta occurring in hospital patients were treated with calcium lactate. Considerable benefit resulted in every case. The drug appeared to encourage the deposition of fibrin within the aneurysmal sac, with recession of the swelling, more rapidly than any other drug I have tried. Two of the patients had previously been in hospital under me for the treatment of their aneurysms, and had then been treated with large doses of iodide of potassium, so that I had the opportunity in these two cases of comparing the effects of the two drugs. Beyond all doubt the calcium lactate acted more rapidly and more efficiently than did the potassium iodide, and without the unpleasant effects produced by the large doses of the iodide.

Haemoglobinuria.—The calcium lactate treatment was employed in three cases, with very marked benefit in controlling the condition in all three cases. A brief description of one of the cases will serve as an example: The patient, a male, aged 57, was first seen two years ago with a history of haemoglobinuria extending over the preceding six months. The attacks recurred during that period every one to three days, and the urine during the attacks resembled burgundy or porter in colour. The attacks were associated with flushing of the face, and coldness and slight oedema of the hands and feet. The haemoglobinuria was quickly and completely checked by the administration of calcium lactate. During the two years there have been a few slight returns of the haemoglobinuria, which can be readily controlled by the administration of a few doses of the calcium lactate, without the patient having to give up his work, which he was formerly compelled to do during the attacks.

Oedema of the Feet on Exertion.—Two cases of troublesome oedema of the feet were treated with calcium lactate. The oedema was neither cardiac nor renal in its origin, and was not due to venous obstruction or any ascertainable organic disease. Both patients had been treated for some time without avail with various drugs, massage, baths, electricity, etc. In both cases there was a marked deficiency in the coagulability of the blood, and both were rapidly cured by the administration of calcium lactate.

Vesicular or Bullous Eruptions.—Three cases associated with deficiency in the coagulability of the blood were treated. In two cases the feet were affected, and in the other case the hands. Other remedies had been tried without avail. All three were rapidly cured by the administration of calcium lactate.

Other Conditions.—Of the following affections, erythema, lichen planus, gouty pruritus, pruritus ani, and perspiring hands and feet with offensive perspiration, one case of each was treated, with success in every case. In all five cases other remedies had been tried without avail. Each of the cases was found to be associated with a marked deficiency in the coagulability of the blood, and fairly rapid cures were effected by the administration of calcium lactate.

SUMMARY OF RESULTS.

Of the cases detailed in this paper it will be seen that 78 per cent. were cured, 9 per cent. were considerably benefited, and in 13 per cent. of the cases no good resulted from the treatment. In none of the 121 cases referred to were any bad symptoms produced by the administration of the calcium lactate, and amongst a large number of other cases treated with that salt, but not referred to in this paper on account of the inability to follow up the ultimate results of the treatment, in only three cases have any unpleasant symptoms been produced which necessitated the withdrawal of the calcium lactate. In those three cases the symptoms that supervened during the course of treatment certainly pointed to some commencing thrombosis, probably caused by the calcium salt. In one case there was a definite slight attack of venous thrombosis in the right calf; in the second case slight numbness of the arms and legs associated with tingling occurred, and in the third case noises in the ear and deafness were produced. In the three cases the unpleasant symptoms rapidly subsided after ceasing the administration of the calcium salt.

Remarks

ON THE

USE OF ALKALIS IN PRACTICAL
MEDICINE.

By EUSTACE SMITH, M.D., F.R.C.P.,

SENIOR PHYSICIAN, EAST LONDON HOSPITAL FOR CHILDREN.

Of the stock medicines in common use none are prescribed with greater frequency than the alkalis. As remedies for all kinds of dyspeptic troubles, for gout and rheumatism in their many manifestations, for urinary acidity and sandy deposits, and in the child for all forms of catarrhal derangements, we turn at once confidently to the alkaline salts. But valuable as these medicines can be in the treatment of disease they must be used with discretion, for, like other drugs, they are only of service when prescribed for appropriate conditions and on a definite plan. There are plain limits which it is important to recognize within which alone their operation can be expected to be useful, and outside of which their influence is calculated to be rather harmful than a source of benefit.

When taken before meals alkalis have first a local action. They neutralize to some extent the acidity of the gastric and intestinal contents, but are most to be valued for their curative influence upon catarrhal conditions of the mucous membrane. To be serviceable they must be prescribed only in moderate doses, and discontinued as soon as their administration has ceased to be obviously beneficial. In excessive quantity the effect of the remedy upon an empty stomach is to increase the secretion of acid. The stomach at once sets to work to neutralize the alkali, and if called upon day after day to make a similar effort, the continued strain cannot fail to be injurious and must increase the weakness of an already enfeebled organ. If the dose be pushed still further so as to overcome in a great measure the acidity of the gastric secretion, the consequent loss of digestive energy must aggravate the derangement and add to the discomfort which the remedy was intended to allay. When absorbed into the circulation the salts increase the alkalinity of the blood, modify its secretions, and if continued too long become a fruitful source of anaemia and languor. Carried out through the kidneys alkalis reduce or annul the acidity of the urine and are at first beneficial, but in immoderate dose or a too protracted course may give rise to cystitis or even vesical haemorrhage. In some exceptionally susceptible patients an alkali taken several times a day, even in ordinary dose, is capable of producing very undesirable consequences. A girl of 10, lately a patient in a London hospital, was found to suffer from cystitis whenever she began a course of potassium citrate. In this child a dose of 10 grains taken three times a day invariably caused the urine to become opalescent in a few hours and turbid and offensive before the end of the week. Fortunately such susceptibility is not common. It must, however, always be remembered, when prescribing alkalis with the object of influencing the renal secretion, that we may reduce the acidity of the urine without necessarily modifying the faulty condition of the system upon which the excess of acid depends.

Alkalis have a local action both upon the stomach and bowels. In catarrh of the stomach their influence for good is very decided; but this appears to be due not so much to their chemical action upon the gastric contents as to their undoubted influence in restoring the deranged mucous membrane to a normal condition. In certain morbid states of the stomach the secretion of gastric juice is exaggerated. This may be the consequence of mild irritation of the gastric mucous membrane, or of mental emotion, or a too sedentary occupation combined with insufficient exercise. The patients suffer greatly from weight or discomfort at the epigastrium and complain of sour eructations and often of vomiting. The power of alkalis to neutralize in any material degree this excessive secretion has been called in question by many notable observers—Trousseau amongst others—and the relief which these remedies undoubtedly bring is due probably to their local action upon the walls of the

stomach. The effect of alkalis is not, however, limited to this local action, for, when used with judgement, they seem to have the power of influencing the whole system for good and setting up a favourable change, which is not always a merely transitory improvement. We often have occasion to notice the prolonged benefit which follows a course of alkaline waters at one of the many spas both at home and abroad. Acting in this manner, the salts of the alkalis are not so much antacids as alteratives—that is, drugs which, given in modest dose for a period of weeks or months, are able, without producing any immediate or striking change, to correct a morbid condition of an organ or of the whole system, and set up an improvement which, if not permanent, is slow to pass away. But it must be kept in mind that to achieve this result the dose of the alkali must be studiously moderate. It is judicious, when using it thus for its more distant effects, whether upon the urine or elsewhere, to employ the citrate or acetate, for these salts, not being alkaline until they undergo a chemical change in the blood, do not tax the gastric energies or call upon that organ for an increased effort, to which at the time it may be unequal. Still, even with these remedies we must be careful to use them with judgement. Directly they begin to produce signs of anaemia, or earlier if possible, their use should be abandoned. We do no good in chronic ailments by impoverishing the blood, and whenever we prescribe drugs which may have such an effect it is essential to keep a careful eye upon the patient to see that the limits of safety are not overstepped.

In gastric derangements the bicarbonates of soda and potash are favourite remedies and are probably equally efficacious. They should be given in moderate quantities—10 to 20 grains are usually sufficient (for children 5 grains to 10), and it is well, as it adds to their curative value, to combine in each dose a few grains of sodium chloride. I have also found that the tincture of colchicum seeds, in very small doses (2 or 3 minims), is a useful stomachic which in cases of dyspepsia forms an addition to the draught of no little importance. When an alkali is thus prescribed purely for its local action upon the stomach, it should be taken before food, and it is advisable, at any rate after the first few days, to make up the mixture with a freshly-made bitter infusion instead of with water. If, however, the object of our prescription is merely to correct acidity, it should be taken two hours after food, and the bitter is best omitted, as its presence in the draught was held by Dr. Prout materially to reduce the neutralizing properties of the alkali.

If there be great irritability of the stomach, the alkaline draught should be made effervescent with citric acid added at the time of administration, and in such a case the inclusion in the prescription of a minute quantity of antimonial wine increases the sedative effect of the remedy. Thus, 20 grains of sodium bicarbonate with 5 of sodium chloride and one drop of antimonial wine in a bitter infusion may be made effervescent with 16 grains of citric acid. It is best to use a quantity of acid insufficient completely to neutralize the soda, so as to leave the draught slightly alkaline. It should be taken three times a day or oftener before food.

The caustic alkalis—the liquor potassae and liquor sodae—have a more decided sedative action upon the stomach than the bicarbonates; and the liquor potassae given in ten or fifteen drop doses with a few grains of potassium nitrate in a bitter infusion is a remedy of very definite value. The liquor potassae acts well also in combination with other stomachics. In cases of continued dyspepsia with obstinate constipation, sleeplessness, and abdominal pains, I have often found speedy relief and prolonged improvement to follow a draught containing twenty drops of liq. potassae with 1 oz. each of infusion of rhubarb and the compound infusion of gentian, taken regularly for a week or longer every morning before breakfast.

Long courses of alkalis are rarely of service in the management of ordinary flatulent dyspepsia, for although very useful in the early stages there always comes a time when their continued administration ceases to be beneficial. As has been said, their chief value consists in their power of reducing an acute or subacute catarrh of mucous membrane. When this has been done and the gastric lining is left flabby and relaxed, a different kind of medication is required. In the treatment of dyspepsia alkalis

rarely do good if the urine is habitually alkaline, or neutral, or only very slightly acid; also, when the tongue is of good colour and clean, or pale and flabby, with marks at the sides indented by the teeth, these remedies cease at once to be appropriate. The soda salts can be borne for a longer time than the corresponding salts of potash, for the latter are apt to have a depressing effect upon the heart, and may have to be discontinued for that reason. The same disadvantage is shared by all the potash salts, and whenever full doses of the chlorate have to be continued day after day, as in the treatment of ulcerative stomatitis in the child, sodium chlorate, which can be given in large doses without risk, should always be made use of.

In addition to the salts of potash and soda, the heavy carbonate of magnesia, and the carbonate of lime are very useful. The former combined with powdered rhubarb is a familiar remedy in every well-ordered nursery, and is invaluable as a preliminary step in the treatment of stomach derangement in the child. For a mild diarrhoea it is better to combine the rhubarb with a few grains of aromatic chalk; for the latter, while in no way interfering with the aperient properties of the rhubarb, heightens its astringent effects. It may be remarked that a teaspoonful of treacle in the draught effectually disguises the nauseous taste of the remedy, and deprives it of its only disadvantage. For infants the dose may be mixed up into a stiff paste with two or three drops of the same sweetener, and smeared by the nurse's finger upon the back of the child's tongue. Given in this way the remedy is not unwelcome to the patient, and runs little risk of being expectorated.

When our object is to neutralize acid in the caecum, the insoluble alkalis are to be made use of, for these are more likely to pass unaltered through the stomach and reach the lower bowel unchanged. The pains often complained of in the lower part of the bowel, caused by local distension with gas temporarily locked up by spasmodic contractions of the intestine, usually yield quickly to the insoluble magnesian salt. The remedy should be combined with a small dose of codeina ($\frac{1}{8}$ to $\frac{1}{4}$ grain) in a draught made stimulating with compound spirits of ammonia and aromatics. In aperient doses these salts produce more irritation of the bowel than is caused by the soluble sulphates of soda and magnesia, and this effect is found to increase by repetition. Trousseau long ago pointed out that when given on successive days the sulphates each time produced less and less effect, while in the case of the insoluble salts the aperient action was more and more marked with each fresh dose of the medicine, and soon led to the passage of mucus, often blood-stained, and evacuated with painful straining.

In addition to their value in derangements of digestion, alkalis are of especial service in the treatment of urinary acidity and the discharge of sand and gravel. It may be the fact, as has been inferred from experiments, that heightening the alkalinescence of the blood does not augment its power of delaying or preventing the formation of gouty deposits, but there is no doubt that increasing the alkalinescence of urine has a decided effect in preventing the deposition of uric acid from that secretion into the kidney and bladder. As Sir William Roberts has remarked, "it is chemically impossible for uric acid to be deposited from an alkaline urine," and it is a matter of common observation that a course of alkaline waters, such as that of Vichy, prevents the deposition of sand as long as its use is continued, and, in spite of experimental evidence I may add, seems to exercise a restraining influence upon acid formation for a considerable time afterwards. In an alkaline or weakly acid urine the uric acid is converted into a urate, and remains in solution at the temperature of the body. By such means it seems possible—although this has been denied—that small renal calculi may be reduced in size sufficiently to pass through the ureters and be discharged. To effect such a result, however, a long course of the remedy is required. As already stated, the neutral salts should be used for this purpose, especially the citrate of potash, for these salts may be taken in moderate dose for a long time without disadvantage. A favourite remedy for this condition in gouty persons is the carbonate or citrate of lithia, but this salt must be used with caution. Lithia is an alkali which is capable of exercising a poisonous action if given in large doses, and cannot, therefore, be used as an alkali of blood or

lymph, as the dose required for such a purpose might have dangerous consequences. It is said also to form an insoluble compound with the triple phosphate of soda and ammonia; and its solvent action upon uric acid, at any rate in the living organism, has been called in question.

The citrate of soda is utilized in the feeding of infants. One of the difficulties met with in fitting an infant with a satisfactory diet is the firm clot formed by the casein of cow's milk in the infant's stomach. This density of clot is explained by Sir A. Wright to be due to a combination of the caseinogen of the milk with calcium salts, and he has recommended the use of soda to replace the calcium in the combination, for the clot thus formed is comparatively loose and easy of digestion. Alkalinizing the milk with bicarbonate of soda is an old practice, but it had this disadvantage, that the calcium when displaced was thrown down and lost to the system. By using the citrate of soda the alkali still joins with the caseinogen, displacing the calcium, while the citric acid unites with the latter base, forming a soluble salt which is absorbed into the circulation. The proportion recommended for ordinary use is 1 or 2 grains of the citrate to each ounce of the milk.

The bicarbonate of soda is an alkali which is often taken for a lengthened period in cases of dyspepsia. In a long course of this remedy each dose should be combined with a few grains of sodium chloride, for the latter salt has the property not only of aiding metabolism, but also of increasing the vitality and power of resistance of the red corpuscles. It also counteracts the tendency of the bicarbonate to form uric-acid concretions. But still, even with this safeguard, the protracted use of the carbonated salt is not to be recommended, for such a course must tend to weaken the digestive energy, and lead before long to anaemia and depression. It may, however, be sometimes considered advisable in cases of severe acid dyspepsia to give large doses of bicarbonate of soda for short periods of time on account of the beneficial immediate effects of the remedy. When there is great acidity of stomach towards the end of digestion from acid fermentation of food, 30 or 40 grains, or more, given in one dose about three hours after a meal, will often quickly allay the more distressing symptoms, especially if the draught be made stimulating with compound spirits of ammonia and aromatics. The painful cramps which often afflict the habitual dyspeptic, especially in the night, may be put a stop to by the same remedy taken at bedtime. Much larger doses than these have been recommended by some, and I myself have heard the late Dr. Piory at the Charité Hospital in Paris recommend 3 to 10 grams (48 to 160 grains) of the bicarbonate to be taken three or four times a day in cases of pyrosis. Such inordinate dosage, however, is quite unnecessary, for this unpleasant symptom is rarely found to resist the action of a few grains (5 to 10) of the compound kino powder given several times a day, as recommended by Sir Thomas Watson. Since the introduction of the salicylate the bicarbonate of soda is now little used in the treatment of acute rheumatism. The two salts are, however, sometimes given together. When the salicylate is prescribed in large doses for the treatment of chorea, the addition of double the quantity of the bicarbonate of soda has been recommended by Dr. D. B. Lees for the purpose of counteracting any depressing effect of the salt, especially the dyspnoea, which sometimes follows excessive doses of the drug. The chief objection to this practice is, of course, the profound anaemia which such medication is liable to induce.

In suppression of urine the bicarbonate of soda given in 40 grain or 50 grain doses every four hours will sometimes quickly promote a return of the secretion, especially if the remedy be combined with a drachm of the spirits of nitrous ether; but the suppression of urine which is liable to occur at the end of an attack of enteric fever or scarlatina is most rapidly brought to an end by a copious enema of hot water (100 F.), which the patient should be directed to retain as long as possible.

The alkaline preparations are also useful in cases of acute bronchitis when secretion is viscid and thick and difficult to expel, for the salts of soda and potash have great influence in increasing the fluidity of the mucus and favouring expectoration. The bicarbonate of soda is usually made use of for this purpose, but is inferior in value to liq. potassae, which should always be preferred,

In cases of acute bronchitis with fever, dyspnoea, and failing acidity of urine, Dr. A. Haig recommends bicarbonate of soda to be given in sufficient doses to make the urine alkaline, and states that when this is done the temperature falls, and all the symptoms are quickly relieved. The quantity required is, however, large—20 to 60 grains for a child and 90 to 120 grains for an adult in the twenty-four hours. The remedy must not be given with ammonia, which lessens its neutralizing power, but may be combined with digitalis as a cardiac tonic.

I will not here refer to the action of those special salts of the alkalis—the bromides of sodium, potassium, and ammonium, the lactate, sulphate and hypophosphite of calcium, and other similar combinations whose influence depends not so much upon the base as upon the element with which the base is incorporated—the union creating a new body with very definite therapeutical endowments. These are ordered not for their general action as alkalis but for their specific influence as remedies for the relief of particular complaints. I may, however, refer in conclusion to another use for the bicarbonate of soda which should not be passed over without due recognition. Just as this salt is beneficial in catarrhal conditions of the mucous membrane for its local action, so it is found to have a healing influence when applied to sores and inflamed surfaces of the body as an external application. Alkaline baths are used largely in skin diseases for the relief of irritation; 2 to 10 oz. of the bicarbonate of soda dissolved in an ordinary warm bath has a welcome soothing effect in cases of eczema, psoriasis, urticaria, lichen, and prurigo. The value of the salt as a local application is best seen, however, in the case of ulcerated surfaces and phlegmonous inflammations. A solution of 15 or 20 grains to the ounce of water kept applied to an intractable ulcer will be found to exercise a surprising influence in promoting the healing of the sore. I have seen large superficial ulcers which had resisted all previous measures begin at once to heal under the use of this simple dressing.

In whitlow, after the escape of the pus by incision or otherwise, the bicarbonate of soda solution applied on lint and oiled silk causes the pain and suppuration to disappear with remarkable quickness. It is unnecessary to increase the strength of the solution, for the value of the application does not depend upon any antiseptic action of the salt; indeed, its activity is far greater than that of iodoform or other antiseptic. It is thought that the effect is due to its local influence in raising the alkalinity of the blood, which has been found by Brucker and others to be greatly reduced in cases of febrile reaction set up by bacteriological intoxications. The same treatment is equally useful in cases of burns, scalds, otorrhoea, leucorrhoea, etc., and the value of the solution as a douche to the pharynx in cases of tonsillitis and septic inflammations is recognized by every one. There is one other use for the bicarbonate which should not be omitted: The aching which often comes on suddenly in a decayed tooth from direct irritation of the dental nerve by acid secretions in the mouth can be quickly relieved by washing out the mouth with the solution. The alkali neutralizes the acid and at once puts a stop to the pain.

WE have to congratulate Dr. C. A. Mercier on a somewhat rare honour, the winning of the Swiney Prize. This, so far as the medical profession is concerned, is awarded only once in ten years. The prize itself is a quinquennial award, but goes alternately to members of the legal and medical professions. There is no competition for it, nor do candidates submit their names to the adjudicators. These are the Council of the Society of Arts, and the Royal College of Physicians, who adjudge the prize to whomever in their opinion has made the most valuable contribution to jurisprudence, either medical or legal, during the previous ten years. The prize, which is a sum of 100 guineas and a cup of the same value, was established in 1844 by the late Dr. Swiney, who died in that year, bequeathing £5,000 to the Society of Arts for the purpose indicated. The cup stands about 24 in. high, and is an exceedingly fine piece of silversmith work, the design from which it is quinquennially reproduced having been prepared by the late Mr. David MacIscle, R.A. The work of Dr. Mercier, which the adjudicators seem to have had specially in view, was his book entitled *Criminal Responsibility*.

An Address

ON THE REMEDIAL USE OF ALCOHOL.

DELIVERED BEFORE THE BORDER COUNTIES BRANCH OF THE BRITISH MEDICAL ASSOCIATION,

BY JAMES MACDONALD, M.A., M.D.,

CARLISLE: PRESIDENT OF THE BRANCH.

IN bringing the subject of alcohol as a remedial agent before your notice a few introductory words of explanation may be offered as to the reasons which have induced me to select this topic for my Presidential address. For the literature with regard to it is generous in quantity; the theme has been worn threadbare by much previous discussion. It is hardly necessary for me to point out to you that for many years alcohol has occupied a prominent place in the medical man's pharmacopoeia. But recently a powerful crusade has been organized against its use, and the leaders in the movement boldly declare that it either possesses no therapeutic efficacy at all, or that its remedial effects could be equally well produced by other drugs. This is the fact that has mainly determined me to take up the subject of alcohol on the present occasion. In the words that I shall have the honour of addressing to you my principal object will be to point out the position of alcohol in the treatment of disease and the uses to which it may safely be applied, where it undoubtedly acts efficaciously, and where its exhibition may be advantageously withheld. In addition I shall endeavour to give some particulars bearing on its later history.

The use of alcohol in the treatment of disease goes back to remote times. Up to a comparatively recent date it was given more or less empirically. With the growth of physiology a scientific element was introduced into the rationale of its administration. A cursory review of the physiological position with regard to alcohol forms, therefore, a natural basis for the present address. What, shortly, is the influence of alcohol in moderate doses upon the heart and blood vessels, the nervous system, and metabolism?

With regard to the precise action of alcohol on cardiac muscle, opinion varies. Drs. Loeb and Bachem in Germany and Dr. R. E. Dixon in this country assert that in small doses it is capable of directly increasing the activity of heart muscle. On the other hand, it is held that this contention has still to be proved.

It is generally agreed that dilatation of superficial blood vessels follows the use of alcohol through the influence of the drug on the vasomotor nerves. In this way the action of the heart is relieved and its efficiency is increased; but when the question of the blood pressure is considered a difference of opinion arises. Physiologists of various countries insist that the pressure is maintained, owing either to a constriction of the vessels in the interior of the body or to an increase in the output from the heart. Other views on this subject of the blood pressure are held by some clinical observers. The medical evidence recently given by Dr. Ralph Stockman before the Whisky Commission has an interesting bearing upon this point. He conducted a series of experiments on himself and on three other medical men with pot-still whisky, patent-still whisky, brandy, and diluted pure alcohols. In the first place, he found that the results produced on the circulation by whisky and brandy were due to their alcoholic contents and not to the residues or distillates—in other words, the action was essentially that of alcohol. Coming to the point under consideration, he stated in evidence that alcohol, taken under conditions of perfect quietude, did not influence the pulse-rate or blood pressure. Under large doses of the drug the blood pressure falls.

Upon the brain and nervous system alcohol does not act as a stimulant. It has, on the other hand, a depressant effect. And it is this sedative, benumbing action of which the physician makes use. "No one," says Schmiedeberg, "will expect any special advantage from a stimulation of the sensations and of the mental functions in disease. We aim rather, as much as possible, at protecting from every form of excitement those areas which are usually in a state of increased sensitiveness, and consequently

keep all strong stimuli arising in the outer world as carefully as possible away from the patient. These efforts are assisted by a mild narcosis which the taking of the wine brings about, even although it be no more than a slight deadening of the hypersensitiveness. Just as rest enlivens and refreshes, so can wine have a like effect by favouring the conditions for rest, although it does not stimulate any function directly."

With regard to the value of alcohol as a food there is a fair consensus of opinion. Graduates of Edinburgh University will recall the interesting lecture of Sir Thomas Fraser on the Life-History of Alcohol in the Human Body. As the result of investigation he found that an average man can consume 1 oz. to 1½ oz. of absolute alcohol in twenty-four hours, according to weight. The products of oxidation did not cause any increase in the amount of carbonic acid or urea excreted, because while still in the body it impaired cell action. On the assumption that it was consumed as food, alcohol has the same value as a carbohydrate of equal weight. Pursuing his experiments upon patients, he observed that in the case of patients on normal diet with steady weight, on the addition of 1 oz. to 1½ oz. of dilute alcohol to the diet the weight was increased; that in patients with a more than sufficient diet and increased weight alcohol increased the weight still further; and that in both of these classes of patients the general health was disordered by the stimulant. On the other hand, he found that when alcohol was given to patients upon a restricted diet with diminished weight, in a few days there was a slight increase in weight, while the general condition was rather better, sleep was secured, and the other functions were satisfactorily maintained. The material point is that the decrease in weight was checked. The conclusions at which Sir Thomas Fraser arrived have been corroborated by subsequent observers. It is hardly necessary to add that alcohol is readily absorbed by the stomach when other nutriment cannot be retained, while it also acts as a stimulant to gastric digestion.

These, then, are the chief physiological data which guide the clinician in the use of alcohol as a remedial agent—the widening of the blood channels with increased flow of blood to the brain and other organs, with a diminished resistance in the peripheral vessels and temporarily increased activity of the circulation, the lethargic action on the brain and the widely admitted fact that alcohol possesses a certain definite value as a food.

Consider, now, in the first instance the use of alcohol in lobar pneumonia. For the past fifty years the treatment of this disease has afforded much material for debate. To-day it is still a vexed question, bristling with points of controversy. On one matter there is agreement—that the present treatment is unsatisfactory. The result is reflected in the figures which tell the story of its fatality. It has been computed that in England and Wales with their population of thirty millions over 220,000 persons are annually attacked by this disease, and that the attendant mortality is 14½ per cent.

If we bear in mind that pneumonia or pneumonic fever is an acute specific infection caused by a germ, the manifest desideratum is an antidotal virus to do for it what serumtherapy has done with happy results for diphtheria. In the absence of a curative serum the remedial treatment is symptomatic. What, then, is the position of alcohol? Assuming that the views of eminent specialists as presented in current medical literature may be taken as fairly indicating the trend of professional opinion, we may advance the general proposition that alcohol, judiciously employed, plays a useful and important part in the treatment of this disease. On the other hand, there is a considerable body of medical men who altogether refuse to admit its efficacy, while there still remain a few practitioners with whom it is an article of faith to treat all cases of this kind with copious libations of brandy; but they are a decadent minority.

The points to which the physician looks for guidance in its use are the state of the heart, especially with regard to the onset of over-distension of its right side, with the small, rapid, feeble, and irregular pulse, the embarrassed breathing, the facial pallor, and the other symptoms of what has aptly been described as "right-heart misery." The presence of rigid vessels is also an indication for its use, as well as the occurrence of delirium.

With some practitioners it is the custom to withhold alcohol until the pulse begins to flag, while others would apply it judiciously throughout. It is the cardinal rule of the many to employ free stimulation with alcohol in increasing doses towards the crisis. Administered on these lines, it is regarded as a valuable and necessary aid to such other stimulants as strychnine, digitalis, and oxygen.

Dr. A. O. Affleck of Edinburgh has recently made an important contribution on this subject. He points out that the same value does not attach to the use of alcohol as a heart supporter as formerly; for most cases it is believed by many to be unnecessary, and that even in the case of the aged and feeble its employment in any but small amount may be harmful. While Dr. Affleck is far from denying it a place in the therapeutics of pneumonia, he believes it to be inferior to strychnine for the heart, a drug which he thinks might often be given with good effect early in the disease.

The views expressed by Dr. Affleck form a link, as it were, with the body of medical opinion which sees no advantage in the employment of alcohol, and is entirely opposed to its use in the treatment of disease. The practitioners of this school are largely identified with the work of temperance reform. The London Temperance Hospital may be looked on as the mouthpiece of the movement. Instituted in 1874 as a protest against the excessive use of alcohol which was then the practice, it has grown in importance, both as regards the scope of its work and the number of its patients. The object for which it exists is to discourage the employment of alcohol and to furnish trustworthy evidence of the results of its disuse. In 1906, with over 1,200 patients on the register, alcohol in the form of rectified spirits of wine was given in four cases, all of which were fatal. Last year (1907) there were about 70 cases of pneumonia under treatment. The medical staff claim that the results they obtain without alcohol compare favourably with those of other hospitals. Whether that be so or not, the unwisdom of forming a broad generalization from a comparatively limited number of cases is obvious. And, besides, in a disease like pneumonia there are many contributory factors and side elements which have to be taken into consideration. The experience of this hospital only serves to show what is generally recognized, that the majority of these cases get well without alcohol. It does not affect the issue in favour of its utility in certain contingencies. I dare say many of you can recall instances where the timely use of alcohol at a critical juncture has turned the scale when life was trembling in the balance. After all, an ounce of practice is worth a pound of theory.

Let me now direct attention to the use of alcohol in the eruptive and continued fevers and submit to you a few impressions drawn from my experience at the Carlisle Fever Hospital.

It is commonly agreed that as a rule, under normal conditions, young children, who form the large majority of these cases, go through the eruptive fevers without the aid of alcohol or any other drug. But there are exceptions. There is, for example, the occurrence of pneumonia in scarlet fever, associated with nephritis, or with gangrenous sore throat—the so-called deglutition pneumonia—or, again, the pneumonia arising independently of these sources. These are all conditions of true croupous pneumonia. For the renal form of the disease there is a direct drawback to the exhibition of alcohol, but in the deglutition pneumonia and in septic conditions generally the use of alcohol has proved of service.

Again, in the treatment of diphtheria in children alcohol has a place. It is useful as an aid to strychnine in the grave attacks of syncope which from time to time occur in that disease with startling suddenness. Repeated vomiting, also, is an obstinate symptom to cope with, especially when associated with a septic state, quick, irregular, or intermittent pulse and albuminuria, indicating severe intoxication. In such conditions, when peptonized food and nutrient enemata have failed, iced brandy has alone been retained by the stomach. Nourished on alcohol in this way, for several days patients have been tided over a critical period and put in the way of ultimate recovery.

To say that many cases of typhoid fever do not need alcohol is a loose way of stating that the disease frequently

runs a mild, uncomplicated course. Alcohol, however, is never given in the local hospital as a matter of routine, and its employment is subject to periodic revision. A frequent low tension pulse with dicrotism, a sustained high temperature with muttering delirium, marked tremor, and septic conditions, these are the symptoms which distinctively call for its use, and which have been found to be relieved by its administration.

A cognate question may arise as to the proper course to adopt in the case of persons suffering from this disease who have been used to taking alcohol habitually to excess. Ought they to be put upon stimulants as soon as they come under treatment on the ground that they are supposed to be dependent upon it, or should alcohol be withheld until the special indications for its employment are apparent? Professional opinion upon this point is variable. Two cases that recently came under my observation at the hospital are of interest in this connexion. The salient points are these. The patients, a man and a woman of middle age, living about four miles from the hospital, were intimated to the local authority in the third week of their illness to have typhoid fever. The man had already had several attacks of intestinal hæmorrhage. To remove patients such a distance, at a critical stage of their illness and under these special conditions, was palpably to contravene the primary canons of precaution in this disease. But in point of home surroundings the state of affairs was most unfavourable. Extraordinary circumstances justify exceptional measures, and as Hadibras says:

For when your case can be no worse
The desperatist's the wisest course.

To say that these persons had been for years addicted to the inordinate use of alcohol is a euphemistic way of stating a plain but pathetic fact. After admission to hospital the cases ran a protracted course of some severity—the man continued to have hæmorrhages for some weeks, the woman suffered from a suppurative otitis media, one of the rarer incidents in this fever. Neither patient, however, presented in a marked degree the special indications for the employment of alcohol, and it was accordingly withheld throughout their illness, which ended in recovery.

The experience of these cases gives a measure of support to the view that the mere history of previous excess is no reason for the immediate exhibition of alcohol. (A series of charts was then exhibited.)

Typhus fever has only an academic interest for the general practitioner. His chief concern and trouble are with the diagnosis. The views of Murchison on the use of alcohol in this disease hold in the main to-day. Patients under 20 years of age do best, as a rule, without it; most patients over 40 are benefited by it from the commencement of the second week, while persons of intemperate habits require alcohol earlier and in greater quantity than others. Typhus, in sharp contrast to typhoid fever, runs a swift, short, definite course, with a crisis like pneumonia. In the sleeplessness and delirium characteristic of this disease, the benumbing effects of alcohol are utilized with benefit. The "perpetual moan" of these patients is turned to "dreamlike ease" under the soothing influence of good whisky and paraldehyde.

The use of alcohol in lobar pneumonia and typhoid fever have been considered in some detail because these diseases are the classic battleground on which the alcohol controversy has been so often waged. Other maladies or conditions will occur to you in which experience has proved the utility of alcohol. As a sedative, for example, in certain nervous ailments, as the modest but serviceable nightcap in the sleeplessness of old people, or as a dietetic in the convalescence from acute diseases, whether it is taken in the form of beer or stout, or the "mellow-tasted burgundy."

On the other hand, there are states in which the use of alcohol ought to be discouraged. It is barred in acute forms of renal disease. In neurotic conditions associated with feelings of depression, where it is taken for the temporary but agreeable relief it affords, it is best withheld. Necessary as it is at all times to bear in mind the insidious qualities of alcohol and the remote pathological effects of its abuse, a special warning must be uttered in dealing with diseases peculiar to women, in view of the fact that of late years there is evidence to show that female intemperance is on the increase.

And now with regard to the administration of alcohol. The admission must be made that even to-day alcohol is frequently given in a haphazard fashion and as a matter of routine. Too often it is allowed merely in deference to the wishes or entreaties of patients or their relatives, who have views of their own on the subject which they are not as a rule slow to impart to the medical attendant. A recent charge of malpraxis has an interesting bearing on this statement, where it was alleged by the prosecution that the lax or wrongful employment of alcohol by a medical practitioner hastened the death of a patient. But if alcohol is to keep its place as a therapeutic agent it must be administered on rational lines. The same scientific precision must safeguard its use as in the case with other powerful drugs, such as strychnine or opium. As with these, so with alcoholic stimulants, a fixed standard of purity must be secured. With regard to whisky, for example, which has lately fallen from favour as a stimulant in disease, owing to the uncertainty of the results which attend its analysis, it is generally admitted that spirit of this kind should be kept in bond for an age-limit of at least two or three years before it is taken out for consumption. Brandy is perhaps more largely prescribed, partly because of its recognized purity, and partly because it has a place in the *British Pharmacopœia*.

But in whatever form alcohol is applied the dosage must be definite—6 oz. to 9 oz. being a reasonable daily range for an adult—its employment must be subject to frequent revision, and it must be at once withdrawn when the object for which it was given is attained.

In the history of therapeutics there is nothing more striking than the remarkable modification that has come over medical opinion during the past thirty or forty years with regard to the remedial use of alcohol. About the middle of last century Allison, Graves, Stokes, and Todd advocated the liberal employment of stimulants in fevers. They based their teaching on the theory that alcohol was an article of food. By their personal magnetism they dominated with their views the rank and file of the profession. And alcohol was given with a prodigal hand. Stokes tells of a patient that "brandy was freely administered to him, and omitted only when the patient showed symptoms of its disagreeing with his brain," a delicate way, surely, of depicting a condition which in those days of large doses must have been far from uncommon. In the case of a year-old child with pneumonia Anstie gave 6 oz. of wine daily and nothing else for twelve days; 24 oz. of brandy with no other sustenance for similar periods of ten days was a customary incident in the case of adults. Bentley Todd gave a girl with typhoid fever and pneumonia 48 oz. of alcohol in twenty-four hours.

The fashion in colossal doses had its day, and a new era of reaction has taken its place. In this connexion Sir Victor Horsley has compiled a set of official facts and figures which bring into sharp relief the altered attitude of medical men with regard to this question. I will not burden you with statistics, but I will try to put the substance of his tables before you in an easily digested form. An analysis of the money spent upon alcohol and milk by several London hospitals was made, giving the returns for one year in each decade from 1862 to 1902. In 1862 the cost of alcohol per bed was £3 8s.; in 1902 it was £1 5s. The cost of milk per bed in 1862 was £1 6s.; in 1902 it was £3 18s. So it appears that in point of consumption milk and alcohol have changed places. In the case of the Metropolitan Asylums Board the cost of stimulants fell from 1s. 4.7d. per head in 1894 to 4.5d. in 1905. These results are supported by the returns from local institutions. At the Cumberland Infirmary, Carlisle, the average annual cost for alcohol and malt liquors during the past ten years works out as follows: Alcohol, 11.5d. per head; malt liquors, 0.6d. per head, or about 1s. in all. During the last three years, 1905-7, the figures per head are: Alcohol, 5.2d.; malt liquors, 0.4d.; total, 5.6d. Alcohol does not enter largely into the treatment of the insane, but the statistics furnished by the Cumberland and Westmorland Lunatic Asylum virtually repeat the above experience. From 1862 to 1906 the average cost per head for wines, spirits, and porter was 1½d. Up to 1900 the cost was always above 1d., in 1875 touching 3d. Since then it has kept below 1d., almost reaching the vanishing point in 1906, when the cost per head stood at ⅓ of a penny.

In commenting generally upon these returns, it will be noticed that they contain no information of the results of treatment. That is an important omission. And, again, the greatly increased consumption of milk in our various hospitals raises a pertinent question: What precautions are the managers of these institutions taking to safeguard the purity of the milk service? It is well known to you that the dangers associated with milk in the way of conveying disease, are many and serious. Existing legislation on the subject is notably defective, while it is common knowledge that the hygienic regulations which are in force are inadequately administered by many sanitary authorities.

Broadly stated, then, it is obvious from the figures which have been quoted, that medical opinion has markedly changed, and there is a fear that following the tendency of reaction, the swing of the pendulum may go to the opposite extreme.

What are the factors that have operated to produce this result? There are, of course, habits or fashions in therapeutics as in everything else. Fashions in the past have sometimes been regulated by the prevailing theory of the origin of disease. In the days, for example, when diseases were set down to inflammation, bloodletting was all the vogue, and the use of alcohol was looked on as a perilous enormity. Then came the period when our bodily ills were ascribed to lowered vitality, and stimulants were administered to therapeutic excess. At the present day the bacterial origin of disease does not materially affect the employment of alcohol, which is generally given with judgement and discretion on the lines which have been indicated.

A consideration of the influences which have tended to lessen the use of alcohol would be incomplete without a reference to the work of the medical advocates of temperance reform. Temperance propagandism, from a professional standpoint began about the end of the eighteenth century. With a Scotsman, not inappropriately, rests the distinction of inaugurating the movement, for a certain Dr. Trotter of Edinburgh, it appears, wrote a treatise on the effects of drunkenness on the human body, which was published in 1804. From that time onwards the history of the agitation has been one of progress. Simultaneously, with the wave of temperance that has flowed over the country in recent years it has taken on fresh activities, and at the present day a group of eminent medical specialists are conducting a vigorous campaign against alcohol.

Every one must admire the unselfishness of their devotion to a crusade which makes for the solution of a grave social problem. The mental and physical deterioration wrought by the abuse of alcohol are evils with which we, as medical men, are only too familiar. But these reformers go further. With much strength of language and on every occasion—in the press, on the platform, and in book publications—they roundly assert that as a food alcohol is useless and as a remedy it is harmful and unnecessary. The profession, it seems, has changed its views on the subject, and in a tone of finality we are told that in the matter of alcohol we are on the high road to therapeutic nihilism. Referring to the hospital statistics which have been cited, they argue that if to the economies effected by the restricted use of stimulants were added the elimination of cases which were due to drink, the thorny task of hospital finance would be solved for ever. With a sublime confidence in the future they base their visionary forecast on the modest assumption of creating a sober nation.

The danger of establishing the habit of inebriety by the remedial use of alcohol is a matter of grave concern to the apostles of temperance reform. They have equipped a hospital to deal with this evil. The distinctive principle of the London Temperance Hospital is to guard patients from the perils that beset them in this way. That exceptional cases do occur which may be put down to this cause is freely admitted. The question, however, is a complex one. It is difficult to collect anything like accurate information on the subject. We know how ready the public are when anything goes wrong to lay the blame upon the doctor. Looking back over the past twenty-five years, I cannot help thinking that this danger has been greatly exaggerated. By caution and discrimination the element of risk should be largely corrected, and, in any

case, the good of the greatest number is the first consideration which overshadows everything.

A favourite device with the opponents of alcohol is to refer to it invariably as a poison. The motive is obvious. In the course of a discussion on this subject which took place in the House of Commons under the late Government, professional opinion was quoted in favour of this view. Speaking to the question, the Lord Advocate said, "As for the medical evidence, we must be driven to the conclusion that in this case as in others doctors differ. When we hear it stated that alcohol is a poison, I wonder if honourable members are aware that the Majority Report of the Royal Commission contained these words: 'We must recognize the fact that most people still regard alcohol as an ordinary article of diet which is only harmful if taken to excess.'" And he concluded: "It is idle to say that alcohol is a poison and nothing more, and that the use of it is inconsistent with any work demanding acute and alert judgement."

A suggestion coming from a society called the International Union of Medical Abstiners was put forth some time ago in the *BRITISH MEDICAL JOURNAL*. It was to the effect that an inquiry be made as to the value of alcohol in lobar pneumonia and typhoid fever, and the International Union has invited the staffs of hospitals in various countries where it is represented to co-operate in the work. The idea is to treat all cases of these diseases alternately with and without alcohol. Apart from the humanitarian aspect of the proposal, I wonder whether, if a member of this union were seriously ill, he would adhere to his guiding principles—if he would remain faithful to his dogma? From a speculative point of view it is an interesting question. It is whispered that a well-known doctor—a professed advocate of total abstinence—was in the habit of taking champagne when his energies were flagging. They often flagged.

Early last year a noteworthy pronouncement on the use of alcohol—strongly traversing the views of medical reformers—appeared in the *Lancet*. It was drawn up by a group of well-known medical experts who, recognizing that in the employment of alcohol the needs of the patient must be the first consideration of the professional man, expressed the opinion so long and generally held that in disease alcohol is a rapid and trustworthy restorative. And the signatories further hold that in many cases it may be truly described as life-saving, owing to its power to sustain cardiac and nervous energy whilst protecting the wasting nitrogenous tissues.

The manifesto discharges a kindly service as a protest against the uncompromising opposition of a body of extremists to the rational use of alcohol. It does more. It applies a spur to the indifference displayed by many medical men with regard to an eminently practical question. It is true that on minor points a divergence of opinion exists, but on fundamental principles there is common agreement. In the past the instruction given in our medical schools on this many-sided question was scanty and inefficient. It is doubtful if the student of to-day is as thoroughly impressed with its importance as he ought to be. If the subject were taught in a sound and systematic manner, the young practitioner would be better fitted to form a judgement on one of the difficult problems that confront him on the threshold of his career. But he would still do well to bring to its solution a broadminded spirit of tolerance and moderation.

To recapitulate, in the foregoing remarks I have endeavoured to trace the position of alcohol as a therapeutic agent. I have shown how in this matter the attitude of the profession has undergone a marked change. A system of excessive dosage has given way to caution and conservatism in its exhibition, and the reactionary tendency to go to the opposite extreme has been indicated. Alcohol is a drug, and as such must be administered with the same precision and discrimination which we employ in prescribing other powerful drugs. Given with these precautions, alcohol is an invaluable remedy in the treatment of disease.

OPERATION AT END OF FIFTH MONTH FOR EXTRAUTERINE GESTATION WITH LIVING FETUS: RECOVERY WITHOUT RECURRENT OR SECONDARY HAEMORRHAGE.*

By ALBAN DORAN, F.R.C.S.,

SENIOR SURGEON TO THE SAMARITAN FREE HOSPITAL.

IN the following case pregnancy began in the left Fallopian tube. The last show, four months before the operation, was no doubt a uterine haemorrhage caused by the abnormal gestation and not a menstrual period, as the fetus was too well developed to represent only four months of pregnancy.

J. E., aged 35, was admitted into my wards in the Samaritan Free Hospital on July 3rd, 1908. She was sent to me by Mr. Poodle, of Sittingbourne, suffering from an abdominal tumour of uncertain nature. This patient was fairly nourished, but her hair was turning grey. Her cheeks were flushed. She had been married for eleven years and her only child was 10 years of age. Since its birth until the present illness there had never been any signs of pregnancy.

History.

On Easter Day, April 19th, when scrubbing her floor, the patient had a sudden attack of hypogastric pain and vomiting, and at once took to her bed. Mr. Poodle noted symptoms of peritonitis with tenderness chiefly to the left of the hypogastrium. A distinct lump was definable in the region of the appendix a day or two later.

The catamenia during the past three years had become irregular, with intervals of seven or eight weeks. They had also grown scanty and painful. I found after careful inquiry that there had been no show of any kind for four months before admission.

The patient was kept in Rochester Hospital for several weeks, and was ultimately discharged at her own request. Mr. Godfrey Taunton kindly informed me: "The physical signs when she was in hospital were: Fullness in the left fornix, slightly impaired mobility of the uterus, which seemed enlarged, the sound passing 2". During the last week of her stay there was distension of Douglas's pouch with fluid. The temperature ranged from 101° to normal. There was no obstruction of the bowels, but much constipation, requiring enemata. There seemed to be no evidence of rupture of a fetal sac; in fact, the only symptoms complained of were abdominal pain and occasional sickness. The patient gave a history of passing a decidua cast, but also stated that she frequently passed something of the kind. I could define no fetus or fluid swelling in the abdomen, and my diagnosis lay between salpingo-ovariis and extrauterine pregnancy."

After her discharge from Rochester Hospital the fullness increased until Mr. Poodle was able to define a circumscribed and fluctuating tumour.

Condition on Admission.

I found the abdomen distinctly distended but not tense. A tumour occupied the hypogastrium, extending as high as the umbilicus. It lay mostly to the left of the middle line, and was hardly movable. Palpation was painful, and set up contraction of the muscles of the abdominal wall. The tumour was more definable on the left than on the right side. Fluctuation was not marked. Distinct gurgling was noted over the right iliac region.

The cervix was thick and short, and closely connected with the tumour in the abdomen. A soft mass occupied Douglas's pouch and the left fornix; it was tender to touch. The sound passed for 4½ in. upwards and forwards; there was no blood or mucus at its point when withdrawn, but some clear glairy mucus. The uterus and mass were almost fixed. The breasts were fairly developed but flaccid; no milk could be pressed out of them. The areolae were well marked; the patient's complexion was naturally dark. The tongue was pale and rather glossy. The bowels, previously regular, had been constipated all through the illness. The patient had suffered from dysentery in 1902 and 1904. The pulse was 84, small, compressible, and distinctly intermittent.

Diagnosis.

I kept the patient under observation for seven days. The temperature did not rise above normal. On July 5th an attack of pain occurred and kept intermitting all the afternoon, passing away before the night. No fetal heart sounds could be heard on auscultation. Not a trace of blood or sanies came away before the operation, and their total absence was somewhat misleading. Although the history suggested ectopic gestation, I rather suspected axial rotation of an ovarian cyst, with

subsequent adhesion of intestine. It is true that there had been absolute amenorrhoea for at least four months if not five, but that symptom has been observed when a patient's health is impaired by the pain and the local peritonitis caused by twisted pedicle; besides, the total absence of haemorrhages is unusual in extrauterine pregnancy. The condition of the breasts and areolae did not absolutely favour the diagnosis of pregnancy; the outer limit of the areolae were sharply defined as in many dark-complexioned subjects when not pregnant. Still, diagnosis was very obscure, as the symptoms of several pelvic diseases which seemed possible in this case are known to be irregular.

Operation.

I operated on July 10th, assisted by Dr. Drummond Maxwell, Dr. Belfrage administering the anaesthetic.

On opening the abdominal cavity I found much intestine adherent to the tumour. On setting the bowel free I noted that the vermiform appendix was quite healthy.

The tumour was now seen to be a big cyst. Its walls were dull and of a deep ochreous colour, such as is seen in an ovarian dermoid after chronic axial rotation. On tapping, a little turbid fluid came away. I then passed my hand behind the cyst, and could feel a fetus lying in its lower part. I pushed the greater part of the cyst gently out of the abdominal wound and carefully enlarged the tapping puncture with scissors till I was able to extract a fetus of about the twenty-fourth week which showed signs of life. The sigmoid flexure ran on the posterior wall of the sac.

Although I took pains to extract the fetus as gently as possible, the greater portion of the placenta was torn away with it. The sac wall bled profusely. I packed the cavity with a long roll of gauze, and as the cut edge of the sac bled freely I made a purse-string suture round it, but I drew on it very little, as the least traction affected the sigmoid colon, which was incorporated with the wall of the sac. The bleeding from the edge was, however, checked by the suture without much traction. On the other hand, the cavity of the sac required repeated packing. I sewed the edge of the sac lightly to the parietal peritoneum and closed the abdominal wound except at its lower extremity, where a portion was left open on account of the gauze packing.

After-History.

There was twice as much for four hours after the operation, and a pad was applied to the lower part of the abdomen. For two days the patient suffered from nausea and vomiting with high pulse.

At 12 p.m. on July 12th, fifty hours after the operation, Dr. Belfrage administered chloroform and I prepared to dress the wound. I feared that the haemorrhage might recur, as in cases recorded by Malcolm¹ and others. In drawing the gauze out of the wound I found that it was saturated with cool blood, but became very thick. When the sac was emptied I was greatly relieved as I noted the total absence of oozing from any part of the sac. About two or three minutes later I passed some dry, absorbent wool into the lowest part of the sac, and on retracting I found that it was not stained with fresh blood. I packed the cavity of the sac lightly with a roll of gauze.

Within seven hours rather free uterine show, the first for four months, was observed, but there was no more oozing from the sac. No traces of decidua came away from the uterine cavity then nor later. Much fetid, bloody fluid collected in the sac for several days after the dressing; it was washed out with antiseptic solutions. The dressing gave the patient great relief; flatus passed freely, and the bowels were easily relieved by enemata. The knot of the purse-string suture came away on July 17th, and the remainder, with the sutures fixing the sac to the parietal peritoneum, were gradually eliminated.

By July 23rd, the cavity of the sac had greatly contracted, so that it had become a sinus. A sound introduced into it passed 5 in. downwards and backwards. On pelvic exploration, the uterus was found to be distinctly movable. The end of the sound which had been passed into the sinus could be felt touching the anterior wall of the rectum behind the uterus.

On August 10th I left the patient under the charge of Dr. Drummond Maxwell. The sinus, as was to be expected, contracted very slowly, and there was some purulent discharge, free from faecal odour.

On September 9th the patient was discharged from hospital. I examined her on my return from a vacation, two days before she left my wards. She had gained flesh, and was in very good general health. The sinus had become narrow and tortuous, discharging a little pus daily. The cervix had undergone very marked involution, having become short and thin, whilst, when I examined the parts before the operation, it was very thick. The sac seemed to have contracted on to the back and fundus of the uterus, the whole mass being to a slight extent movable. The right fornix and Douglas's pouch were free. A slightly tender body, feeling like the ovary, could be defined in the left fornix. There had been no period since the operation.

On December 1st Mr. Poodle informed me, in reply to a letter, that the patient was very well in general health, and only complained of a feeling of soreness over the left inguinal region. The sinus was gradually getting shallower. Menstruation had recently occurred but the show was scanty.

The Fetus.

The height of the fetus was 23 cm., or nearly 9 in. The hairy scalp was distinct, the eyebrows well developed. The skin was almost opaque, not wrinkled, and bore no distinct lanugo. The

* Read at a meeting of the Obstetrical and Gynaecological Section of the Royal Society of Medicine, December 10th, 1908.

limbs were well developed, with perfect hands and feet, bearing equally perfect fingers and toes; the nails were very short. The external organs were of the female type, distinct and without any visible anomaly; meconium escaped from the rectum, and there was no sign of spinal deformity, fissures of the lip and palate, or ectopia of the viscera. This fetus moved its limbs and distinctly cried when extracted, and it showed signs of life for some minutes after delivery. At the end of the fifth month the fetus of intrauterine pregnancy measures about 25 cm. in height. Granting that an ectopic fetus is less well-developed, especially as regards nutrition, I think that the proportions in this specimen indicate that the pregnancy had advanced to the end of the fifth month.

Placenta and Cord.

The placenta, as I have already stated, was torn through during extraction. The greater part, very thick, appeared quite normal; but at the edge there was a large infarct, over 2 in. long by 1 in. broad and 1 in. thick. The laceration during extraction seemed to have begun on the brittle tissue of this infarct. The portion of the placenta removed, some 4 in. in width, included the umbilical cord, which was 8 in. long.

The acute attack of pain on April 19th seemed to indicate rupture of the tubal sac into the left broad ligament, and a "posterior tubo-ligamentary pregnancy" (Taylor), as I found it to be at the operation. The lower boundary of the sac, in that case, was therefore the rectum. The pressure on the bowel caused constipation, as Mr. Tannton reported, and as was the case after admission into my wards, until the removal of the gauze packing. The placenta was not attached to the bowel, else there might have been diarrhoea (Freund). The fetus was living, therefore *Bacillus coli* infection, not rare in posterior tubo-ligamentary pregnancy, had not taken place.

The most important question, however, in regard to this case is the treatment of the sac. I fail to see how I could have adopted any safer method than that which seemed to me the only way to save the patient's life. The tearing through of the placenta was accidental, whilst on my attempting to remove the remainder so much haemorrhage occurred that I left it alone and packed the sac. Arterial blood spouted from the cut edges of the sac, but the purse-string suture checked it at once. The sac was secured to the lower edges of the abdominal wound, otherwise the packing would not have been effective. The packing was removed on the second day and the haemorrhage did not recur.

On the other hand, the disadvantages of this method, inevitable under the circumstances in my case, were clearly manifest to me. The cyst wall, let it be remembered, consisted not only of the posterior layer of the broad ligament but also of the adjacent peritoneum of Douglas's pouch. Therefore, when I drew tightly the purse-string suture on the cut edge of the cyst wall, the large intestine was dragged down, forming a sharp angle, so that obstruction would have occurred had I not relaxed the suture considerably. Then this same suture, as well as those which fixed the edges of the sac to the wound, did not come away until much local suppuration had taken place and the pus mixed with the sanies from the remains of the placenta made up a fetid semifluid substance which necessitated daily dressings of the sac.

Lastly, I dreaded the spread of the suppuration, as in Dr. Herbert Paterson's case;² but I feared much more the recurrence of haemorrhage, as in Mr. Malcolm's, to which I have already referred, and fortunately there was no more bleeding, and the suppuration did not extend. Still, I understand that Dr. Paterson and others find that sutures and ligatures may be dispensed with in the treatment of the fetal sac late in pregnancy, and I desire to learn how far this method guarantees the patient against that essential and imminent danger, never absent when the fetus is alive—namely, haemorrhage.

At the annual meeting of the Wolverhampton Sunday Hospital Collection Committee it was reported that the income was £534 as compared with £553 in the previous year. The money has been allocated as follows: General Hospital, £447; Eye Infirmary, £93; Women's Hospital, £49. The expenses have been slightly reduced.

A CASE OF TUBAL PREGNANCY WITH EARLY OPERATION.

By HOWARD F. WARNER, M.B., B.S. Lond.,

M.R.C.S. Eng., L.R.C.P. Lond.,

RAYWARD'S HEATH.

The interest in this case lies not so much in its rarity, for such cases are by no means uncommon, but in the somewhat puzzling nature of the symptoms, their comparative mildness, and in the short period after actual rupture at which the abdomen was opened.

Mrs. X., aged 42, married three years, had had no children, but one very early miscarriage about two years ago. She had always suffered from spasmodic dysmenorrhoea, menorrhagia, and, since marriage, from dyspareunia. She complained that for two days she had had abdominal discomfort and pain passing through to the sacrum, exactly similar to the pain generally experienced with the menses, but more acute. She had hitherto been always regular, but at the present time was about one week overdue, and though there was a "show," the flow was not as copious as usual. There was great pain on attempting to micturate and considerable difficulty; the pain was also felt passing through into the rectum and in the right iliac fossa.

The patient was of a very neurotic temperament, and considering her age and previous menstrual history it seemed probable on the first visit that the symptoms might be due to a somewhat early menopause. Hot turpentine fomentations, warm douches, and rest in bed, together with a placebo, were ordered, and on the following day the pains were much better.

I heard nothing further of the patient for seven days, during which time she had been gradually getting about again; then

Posterior view of specimen. A, Glass rod passing firstly through secondary rupture in broad ligament, and then through primary rupture into the tube; B, external limit of sac in tube—the rod will not pass beyond this point; C, divided end of tube; this is closed up; D, osium abdominale (closed); E, broad ligament, cut edge; F, ovary.

I was sent for, to find that the pains had come on again, and were now of a definitely colicky nature, the flow had become more profuse, and trouble with micturition was again present. On examination the patient complained of tenderness all over the abdomen, which, however, moved well on respiration; deep pressure was impossible anywhere, but the tenderness was most marked just above the pubes, in the right iliac fossa, and in the right loin. She also stated that the pain from the loin radiated downwards to the vagina and down the right thigh. The kidneys were not palpable, there was no superficial tenderness anywhere, and beyond determining that muscular resistance was greater in the right iliac fossa than in the left, the abdominal examination was very unsatisfactory owing to the general deep tenderness. There was no jaundice and no history pointing to gall stone. At this time the temperature was 98°, and the pulse (taken at the end of the visit) was 84, the tongue was furred and moist, but the general appearance of the patient was quite good. The attacks of pain lasted about half an hour and "doubled her up"; there was sweating with the pain, but no vomiting, and during the attacks she had felt faint, but there had been no loss of consciousness. She was not anæmic. The urine contained no pus, and, owing to menstruation, it was impossible to attach any value to the presence of blood, but at this time I thought the diagnosis lay between renal colic, tubal pregnancy aborting, and possibly appendicitis.

Vaginal examination revealed an enlarged and very tender cervix; the uterus was freely movable, normally placed, and extremely tender, giving the same pain as the dyspareunia on being touched; owing to the tenderness nothing further could be made out, except that the rectum was fuller than it should have been if the history were correct. Rectal examination

revealed nothing further, and no swelling could be felt in the pelvis. Castor oil was given and morphine $\frac{1}{2}$ grain, hypodermically, and two morphine suppositories ($\frac{1}{2}$ grain) were used at intervals during the night.

On the following day the condition had completely changed. The temperature was 99.5° and the pulse 120; the face had a definitely abdominal look, and for the first time the general appearance of the patient was not satisfactory. The pain was now mostly referred to the umbilical region and pelvis, and there had been vomiting as the result of the hypodermic injection of morphine on the previous day. The patient was restless but not anxious, and was not anxious about her condition when not actually in pain. The pain was now more continuous and less colicky: the bowels had been freely moved three times after the castor oil, the motions being entirely liquid. Considering the diagnosis again I thought it unlikely that appendicitis could have lasted so long (twelve days) without any pyrexia hitherto, without the pain becoming localized and with the general condition keeping so satisfactory in spite of the diffuse abdominal pain, and also in the absence of general peritonitis to account for the diffuse pain. Renal colic was now unlikely, as most of the pain was umbilical and pelvic, was more continuous, the temperature was now raised, and the hypogastric facies was becoming marked, and above all, the history of the case, revised in the light of its subsequent development, seemed to take on a new significance. I diagnosed right tubal pregnancy, probably aborting, and called in Mr. Buck, of the Sussex County Hospital, who came on the following morning.

Operation.

An anaesthetic was given, and with the muscles thoroughly relaxed it was possible to make out a doughy resistance in the right lateral fornix per vaginam, but nothing of the nature of a pelvic swelling; a small subserous abscess was also felt in the anterior wall of the uterus (which doubtless accounts for other points in the patient's history); by the abdomen the examination was still negative. On opening the abdomen a swelling about the middle third of the right Fallopian tube was found, and a clot of blood rather larger than a walnut was adherent to the posterior surface of the broad ligament just below the tube. The tube, ovary, and part of the broad ligament were removed in the usual way, and less than a tumblerful of blood clot was found in Douglas's pouch and removed, and the abdomen closed.

On examining the specimen it was seen that the tube had ruptured into the broad ligament (possibly during the first attack of pain thirteen days previously), and that the broad ligament was now in the act of discharging the ovum through a small rupture on its posterior surface which must have been very recent on account of the very slight haemorrhage which had occurred, and was probably synchronous with the change for the worse which had occurred on the previous day, this being the first time that the peritoneum had actually been involved.

The ovum in this case cannot, at most, have been more than five weeks old before symptoms began, which in itself makes the case somewhat unusual, though by no means a record; but the interesting point, and one which should be emphasized, is the importance of early operation in doubtful cases of ectopic gestation. The haemorrhage (internal), pain, sleeplessness, and anxiety, if allowed to continue in the hope that medical means will suffice, must vastly prejudice the patient's chances when operation ultimately becomes necessary; and the surgeon is too often called in after the patient has been "watched" almost into the world to come, when the dangers, both operative and post-operative, are vastly increased, and at the best a slow and tedious convalescence is the result.

PERFORATIVE PERITONITIS FOLLOWING ENTERIC FEVER: OPERATION: RECOVERY.

By H. B. MYLVÁGANAM, F.R.C.S.,
SURGEON, GENERAL HOSPITAL, COLOMBO, CEYLON.

ALTHOUGH operative treatment for perforative peritonitis following enteric fever is the rational method of treatment, and although, at any rate in Colombo, such cases are frequently seen in the medical wards of the General Hospital and diagnosed early, the condition of the patients is so seldom favourable that surgeons rightly refrain from interfering with such cases. The vitality of a patient already lowered by this toxic disease, may not stand the additional strain of an operation attended with shock, under an anaesthetic. On the other hand under favourable circumstances, when such cases are left alone and if the severity of the primary infection is not great, there is some chance of such a case developing localized peritonitis and the inflammation terminating in an abscess which can be opened and drained under local anaesthesia.

Improved aseptic precautions and saline transfusions

and injections of strychnine, etc., constitute the armament of the present-day surgeon to oppose the danger of shock and secondary infection following laparotomy. But with all these precautions, who can foretell what course the primary disease is going to run? Therefore, it is always with a great deal of diffidence that a surgeon undertakes to operate on such cases.

This report is based on a case successfully operated on by me in December, 1907, and I may mention that it is the very first case ever successfully tackled in Ceylon. A few months ago, prior to this case, my colleague Dr. T. F. Garvin and I operated on a similar case, but the patient survived only three days after the operation.

The patient, a fairly-nourished male, aged about 30 years, was admitted into the General Hospital, Colombo, on December 14th, 1907, with the usual symptoms of peritonitis.

History.

It was elicited that he had been suffering from a mild type of fever and headache for some days prior, but that his illness had not been severe enough to confine him to his bed. In fact, he was discharging his duties as an attendant of the Victoria Eye Hospital until the day previous, when he felt a sensation inside his abdomen as if something had given way while he was lifting a heavy lotion bottle. This was soon followed by acute pain in the abdomen, vomiting, and tympanites.

On admission the abdominal parietes were rigid and tender; tympanites was well marked, obliterating even the hepatic dullness; the bowels were constipated, and the right thigh was flexed. Pain was referred to the umbilicus, where tenderness was most marked. The tongue was dry and furred. Pulse 108, rapid, but of fairly good tension; temperature 102° F. Mr. Buck assured me that he had given a castor oil and turpentine enema and half a grain of calomel internally.

Diagnosis.

When I saw the case I decided to operate at once. I was mainly influenced by the favourable condition of his pulse and his general appearance. Four of my colleagues who happened to be at the time at the hospital also saw the case, and the diagnosis arrived at was either perforative peritonitis caused by the rupture of an ulcer of the bowel in an ambulatory typhoid, or of a gangrenous appendix.

Operation.

I made a median incision under chloroform, extending from the umbilicus to the pubis, and on opening the peritoneal cavity exudation lymph was seen, and gas escaped. The small bowel was inflamed, and the coils about the region of the umbilicus were adherent by recent lymph. The escape of gas led me to think that there was undoubtedly a perforation of a hollow viscus. I first examined the caecum and the vermiform appendix, and found them quite intact. When I traced the ileum from its junction with the caecum upwards I discovered, about 2 ft. from the caecal end, a perforation large enough to admit the tip of my little finger. The surrounding area was infiltrated and thickened. There was extravasation of faecal matter among the coils of the gut. My attempts to close the perforation with Lambert sutures were frustrated by the sodden condition of the bowel, but I managed to close the perforation without much delay, and mopped out the peritoneal cavity below the level of the umbilicus with gauze mops soaked in normal saline. I did not disturb the bowels above or resort to irrigation of the peritoneal cavity—a practice which I have long since discontinued. A gauze drain was placed in the recto-vesical pouch, and the abdominal incision closed in three different layers. The perforated bowel was gently wrapped up in the free end of the omentum and placed just below the abdominal wound. Two pints of normal saline was transfused into each arm-pit, and strychnine and adrenalin was each injected hypodermically. The pulse after the operation was 140. At 10 p.m. it was 108. The patient was fairly quiet; the saline and strychnine injections were repeated. At 12.30 a.m. the pulse was 118 and of fair volume. He complained of thirst. He was placed in Fowler's position and a saline enema (about 8 oz.) was given at 4 a.m.

Next morning (7.50 a.m.) the pulse was 120 and small. He had slept fairly well, complained of no pain over the abdomen, and had passed urine naturally; no motions and no flatus had been passed. The temperature was 101.2° F. A saline enema (5 iv) was ordered every third hour, and turpentine capsules (m.v. each) every fourth hour. At 4 p.m. the pulse was 120; he had passed flatus, but there was slight tympanites present. The turpentine was omitted; and eserine sulphate $\frac{1}{2}$ grain in a drachm of water given every second hour. At 8 p.m. the abdomen was tympanic and distended; no flatus had passed; the pulse was small and rapid. The turpentine capsules were repeated. At 9.30 p.m. he had vomited once or twice; the pulse was 120, and he had abdominal pain. He had had no sleep, and tional 15 grains was ordered.

On the morning of December 16th the temperature was 98.4° F., the pulse 106 and of fair volume. He had passed flatus and the tympanites was much less. He had vomited several times, and had pain over the abdomen. The dressings were removed; the discharge was offensive and slightly recalcitrant in odour. In the evening the temperature was 101.4° F., the pulse 124. Pain was much less; he had passed flatus and felt more comfortable. Eserine was repeated every fourth hour.

On December 17th the temperature in the morning was 100.6° F.; the pulse 108, of good volume. He had passed a motion on the previous night. Respiration was less laboured. Flatus had been passed; abdominal distension was much less and the patient felt better. A morphine injection was given at bedtime.

On December 18th the pulse was 126; he had slept well. In the evening he passed five loose motions. Morphine was repeated.

On December 19th the pulse was 110; he had slept very well; the bowels had been moved three times only. Bismuth and morphine was given internally. The abdomen became distended, but this was relieved by a soap enema.

On December 20th the morning temperature was 99.8°, the pulse 108 and of good volume. He had passed only one motion, and had slept well after a chloral and bromide draught.

From December 21st to 27th the temperature ran an irregular course; the bowels also moved freely, but no attempt was made to check the motions completely, as it produced distension and discomfort. Whenever the motions were too frequent bismuth and morphine were given internally. In the meantime he was given digitalis and nuxvomica in a mixture, and was fed on cow's milk, malted milk, chicken broth, liquid peptonoids, brandy, etc. From December 27th, 1907, to January 1st, 1908, his temperature was normal, but there was then again a slight rise, not exceeding 99° F.

The abdominal wound became infected, and had to be dressed daily. At one time a little faecal matter passed through the lower end of the wound, but it has since ceased. Now the wound is almost healed, and the patient is enjoying ordinary diet. Vidal's test proved negative three times.

Irrigation of the peritoneal cavity at the time of the operation is not attended with the best results. I believe it tends to spread the infection all over the cavity, and at the same time dilutes the antibodies formed by the organism to resist the invasion of the micro-organism; therefore the less the interference the better the result. Gauze drainage acts much better than rubber tubes by virtue of its capillary attraction. After the fourth day the abdominal cavity may be irrigated with a mild antiseptic lotion such as sterilized boric, as was done in this case.

I must express my gratitude to my house-surgeon, Dr. T. de Krelser, for the great attention and care bestowed on this case.

ON THE METHOD OF MEASURING THE SYSTOLIC PRESSURE IN MAN, AND THE ACCURACY OF THIS METHOD.

BY

LEONARD HILL, and MARTIN FLACK,
M.B., F.R.S. B.A., B.M.Oxon.

THE systolic pressure is usually obtained by means of the armlet or cuff independently invented by Riva Rocci and Hill and Barnard. The armlet may be used with a mercurial or spring manometer. The pressure is raised until the radial pulse is obliterated, the armlet being applied at the level of the heart to avoid the influence of the hydrostatic pressure of the column of blood in the body, and so obtain the true systolic pressure of the heart. One of us (L. H.) has perfected recently a form of sphygmometer which serves the same purpose as the armlet and mercurial manometer, is as accurate, far simpler and quicker in use, and can be carried in the waistcoat pocket. The instrument consists of a rubber bag, about 1½ in. in diameter, and enclosed in a silk cover, which is connected by a short length of tubing to a straight glass tube—the gauge. The gauge is carried in a case like that of a clinical thermometer. It consists of a tube open at one end and expanding into a small air space at the other end. Near the open end is a side hole. The closed end is formed of an inch of solid glass to hold the gauge by, so that the air space is not heated by the fingers. On placing the open end of the gauge in water the water rises up to the side hole and forms a meniscus there. This is the zero of the scale, the tube being graduated up to 250 mm. Hg. The tube of the bag is slipped over the open end so as to cover the side hole. The bag must not be blown out to distension, but be about two-thirds full of air. The subject is given the gauge to hold by its solid end; and the observer takes the wrist of the subject, places it at the heart level, and, covering the bag

with his fingers and palm, presses it down over the radial artery, his thumb being behind the wrist. With the index finger of the other hand the observer keeps the radial obliterated to prevent a pulse re-entering from the anastomosis with the ulnar artery. With his second finger placed between the index and the bag he feels when the pulse is obliterated by the pressure of the bag, and then reads the position of the top of the meniscus in the gauge. The bag, being large, flaccid, and entirely enclosed by its silk cover and the fingers (its tube escapes between them), takes the place of the leather cuff and the bag of the armlet. Small unenclosed bags give untrustworthy readings, for part of the pressure applied goes in distorting the rubber bag, and is not transmitted to the artery. After use the fluid is jerked out of the gauge. Care must be taken on refilling that there is no water in the side hole, to prevent the meniscus rising. The side hole can easily be cleared by blowing into it, and the orifice of the tube can be cleared by the bristle of a nailbrush. The instrument is made by Mr. Hicks, 8, Hatton Garden, E.C.

Considerable doubt as to the accuracy of the obliteration method of measuring the systolic blood pressure has been expressed recently, particularly by Dr. William Russell.¹ It has been asserted that much of the pressure applied by the armlet method may go to compressing the stiff wall of a degenerated or contracted artery. Herringham and Womack have just published a series of observations in which they found that the resistance of the wall of the *post-mortem* brachial artery may vary from 4 to 34 mm. Hg. They say that the resistance does not vary with age; that at every age exceptional cases occur; that the extremes vary greatly and irregularly; that the two brachials may differ by as much as 10 mm. Hg. The same was found true of the carotids and iliacs. Their results, in our opinion, point to varying *post-mortem* contraction of the arteries as the cause of the resistance—*post-mortem* contraction which is excited by injury and relaxed by freezing, and has been so fully and ably studied by MacWilliam.² We have no right to assume that much *post-mortem* contraction occurs in the living artery. This contraction is the natural response to injury which causes the closure of cut and torn arteries. Moreover, it is a well-established fact that obliteration of a living artery excites it to relax, and thus renders error from the resistance due to a contracted state unlikely. We have tested the accuracy of the obliteration method on man in the two following ways, and both ways, as far as our tests go, show that the method is an accurate one.

I.—THE GRAVITY METHOD.

It has been proved by Mummery and also by one of us (L. H.) that the obliteration pressure in the femoral of the dog is the same (within 1 or 2 mm. Hg) as the systolic pressure taken in the opposite femoral with a cannula and Hürthle manometer. It has been proved by one of us (L. H.) that in a dog placed in a vertical posture, head upwards, the pressure in the femoral artery is higher than in the carotid by the hydrostatic pressure of the column of blood which separates the two points of measurement, while, if the dog is turned head downwards, it is higher in the carotid than in the femoral by the same column of blood. The pressures were measured directly with cannulae and mercury manometers.

Carrying out similar observations on man with the aid of two armlets and two mercurial manometers, we obtained like results. It is very improbable that this would be the case if the resistance of the arterial wall entered into the readings, for the contraction of the arteries varies with the pressure they have to support and with the control of the vasomotor nerves, and both factors are modified very greatly by change of posture. In the case of sclerosed arteries, it is unlikely that any two of them would be degenerated and stiffened to a like extent.

On students we have placed one armlet round the upper arm and another round the calf, and used the pulse in the radial at the wrist and posterior tibial artery at the ankle as the index of obliteration. One of us controlled the pump and read the manometer, while the other felt both arteries and signalled the moments of obliteration. It is essential that the readings of the two arteries be taken together and not successively, to avoid errors arising from oscillations of pressure due to the varying attention or excitement of the subject.

We took the readings with the student (1) lying supine in the horizontal posture; (2) standing with the observed leg relaxed and the weight thrown on the other leg; (3) lying supine with the legs raised into the L-shaped position; (4) hoisted up by rope and pulley into the vertical head-down posture, the rope being attached round the foot of the leg which was not observed, and the observed leg attached to this leg by a bandage, so that the posterior tibial artery could be felt at the ankle.

The readings were taken both on raising and lowering the pressure repeatedly and the average taken.

Subject.	Posture.	Brachial Artery. Pressure in mm. Hg.	Posterior Tibial Artery. Pressure in mm. Hg.	Difference in mm. Hg.	Height of Column separating in cm.	Difference Calculated from Height of Column in mm. Hg.
H. H. R.	Horizontal	140	138	2	—	—
	Standing	136	204	68	89	63.5
	L posture, legs up	122	76	46	60	46.1
	Vertical head down	148	70	78	1010*	77.7*
P. H. R.	Horizontal	126	126	—	—	—
	Standing	140	204	64	86	66.1
	L posture, legs up	132	78	54	65	50.0
	Vertical head down	116	42	74	91*	70.0*

* The arm was not in quite the same position in regard to the heart level as in the standing posture. It had sunk headwards, so that the column of blood separating the two points of measurement was longer.

Considering the difficulty of reading sharply the return of the feeble posterior tibial pulse in the head-down posture, the agreement of the calculated and observed differences is astonishingly near. A most interesting point in these observations is the indication that they give that while the pressure which the heart has to overcome does not alter greatly, the pressure in the cerebral arteries is kept approximately the same in the horizontal, standing, and vertical head-down postures, in spite of the enormous differences in the effect of gravity.

Thus, in P. H. R. the pressure at heart-apex level was approximately 125 in the horizontal posture, 140 in the standing, and 110 in the vertical head-down posture. The vertical distance from base of brain to armlet in the standing posture was about equal to 20 mm. Hg; so that, deducting this amount, the pressure in the circle of Willis would be about 120 mm. Hg. In the vertical head-down posture the subject kept his head bent up somewhat, so that the vertical column separating armlet and base of brain was less—say, equal to 10 to 15 mm. Hg; and, adding this, the pressure in the circle of Willis would be about 120 mm. Hg. In the horizontal posture it was actually 126 mm. Hg. In the case of the arteries of the legs there was no such regulation. At the level of the calf the pressure was 126 in the horizontal, 204 in the standing, and 42 in the vertical posture. The regulative mechanisms engaged are (1) constriction of the arteries, (2) the output per minute of the heart, (3) support of the venous and capillary system by the muscles, (4) the respiratory pump. In the standing posture the pulse is more rapid, the arteries in the abdomen and limbs constricted, the skeletal muscles braced up, the respiratory pump more active.

In the case of patients with high arterial pressure we have applied the gravity method to the two brachials, one arm being held up and the other down, and the pressure read in two armlets at the same time.

In one case of aneurysm, the systolic pressure varied so much with successive beats that no good readings could be obtained.

Our second method, we think, proves with certainty the accuracy of the obliteration method. We have, it is true, up to now tried it in only a few cases, but we commend the trial of this method to those who wish to test the matter further on cases where readings are high and arteries thickened. We place one armlet round the

Case.	Difference in Height Measured equal to mm. in Hg.	Difference in Pressure Observed.	Arterial Pressure.
Sclerosis, anging pain, emphysema	17.0	17.5	140
Chronic nephritis, thick arteries	10	10	185
Diabetes, small con- tracted arteries	15.2	15	175
Chronic nephritis, ar- terio-sclerosis	11.6	12	197
Paraplegia	11.55	11	175

Many experiments on healthy subjects gave the calculated reading within 0.2 mm. Hg.

brachial, and another narrower one round the forearm of the same arm. We find the obliteration pressure with the first armlet. Suppose it is 150 mm. Hg. We lower the pressure in this armlet to, say, 145 mm. Hg, so that the arterial blood can get through into the limb, but cannot get out of the veins of the limb until the pressure in the veins rises above 145 mm. Hg.

Allowing sufficient time for the veins to fill, we then measure the pressure in one of the superficial veins, and find that it does finally reach this pressure thus: We raise the pressure in the second armlet above 1.45 mm. Hg, and choosing a suitable vein above this armlet, by stroking, empty it upwards past the next valve, then quickly lowering the pressure in the second armlet observe the pressure at the moment when the vein fills from below. One of us watches the vein, and signals the moment of filling; the other the manometer. We repeat this observation several times. Now if we find the pressure in the vein reaches 145, we know that the obliteration pressure was correct within 5 mm. Hg, for no one can suggest that the wall of a superficial vein offers any noteworthy resistance; and as the venous pressure is found by the second armlet to be 145 mm. Hg, and equal to the pressure in the first armlet, and as the pressure in this is within 5 mm. Hg of the obliteration pressure, the latter is proved to be correct within 5 mm. Hg.

Subject.	Obliteration Pressure.	Pressure Main- tained in Brachial Armlet.	Pressure Measured in Veins of Forearm.
G. T. ... Sclerosed arteries	156	150	148
F. T., aged 59	122	110 114	110 114
G. ... Pipe-like arteries full of plaques	156	120 130	118 176
G. M. ... Hard arteries	148	142	140
T. C. ... Granular kidneys, thickened tortuous arteries	194	184	100 First reading. 110 Second .. 140 Third .. 180 Final reading after waiting long enough for venous pressure to rise.
A. J. ... Phthisis, tortuous arteries	(1) 106	100	40 First reading. 80 Second .. 100 Final ..
	(2) 106	95	36 First .. 72 Second .. 92 Final ..
	(3) 106	100	40 First .. 60 Second .. 58 Third .. 92 Fourth .. 102 Final ..

We have also tested the method on several normal men.

To carry out this method properly a vein must be chosen which does not fill from above, or, at any rate, not quickly. With such high pressures in the veins the valves

leak, and in some cases the leakage is such that we have not been able to carry out the method. A slender vein can generally be found which answers the purpose. The pressure in the second armlet must be lowered quickly directly the vein has been stroked empty, so that the filling of the vein from below may be observed before it can leak full from above.

In cases of high pressure it is difficult to get patients to endure long enough the somewhat painful feeling of pressure which results from the maintenance of the first armlet at a pressure close to the obliteration pressure. It is necessary to work quickly in these cases, and give a rest between each test.

TREATMENT OF INOPERABLE CANCER BY HYPOCHLORITES.

By JONATHAN E. A. G. BECKER, M.B., C.M.E.DIN.,

LONDON, S.W.

DURING the past three or four years I have, when called upon to deal with cases of inoperable cancer, employed a method of treatment which is entirely novel so far as I am aware. The cases in which I have carried it out thoroughly are not numerous, and at present only the three recorded are of sufficiently old standing and sufficiently verified as regards diagnosis.

1. *Secondary Invasive Growth—CASE I.*

A woman employed as a cook in a large block of flats in London. In October, 1901, ovariectomy was performed on her at Guy's Hospital and the right ovary removed. Little relief from her previous symptoms resulted, and she continued to attend as an out-patient, the uterus being curetted on two or three occasions. As she continued to fail in health she was readmitted in November, 1902. On laparotomy a mass was found in the pelvis, suggesting a malignant growth with secondary deposit in the omentum. No microscopic examination was made, but from the relations of the mass and its appearance it was concluded that it was a case of malignant disease. Consequently the abdomen was closed without further interference, and the patient discharged in February, 1903.

Ten months later, or in December, 1903, the special treatment in question was commenced. By May, 1904, five months later, the patient was so far recovered that she was able to do all her household work and to go out bicycling, riding as far as thirty-five miles in a day. In appearance and feeling she was perfectly well. Nevertheless, the treatment was continued for several months longer. At the date of writing, four years later, this patient is still in good health and earning her living by her own exertions.

CASE II.

A woman who had a radical operation for mammary carcinoma at Guy's Hospital in March, 1907, the diagnosis of cancer was verified by microscopic examination. Two months after she had been discharged, some enlarged glands were noticed on the left side of the neck, and these were removed surgically at the Soho Hospital for Women. Again, two months later, further growth was observed in the same locality, whereon the special treatment was commenced. In two months' time the growth had disappeared, and at the time of writing, eighteen months later, she is in absolutely good health, feeling well, taking active exercise, and pursuing her ordinary occupation—that of a school teacher.

CASE III.

A French gentleman, who, through a bicycle accident, received a blow on the right breast. A tumour formed, and was diagnosed in May, 1904, as a malignant growth. In consequence a radical operation was performed at King's College Hospital in the same month, the growth, on microscopic examination, being found to be a spindle-celled carcinoma. The patient was seen now and then by his surgeon, and in 1906, though the cicatrix seemed in good order, the conclusion was reached by this surgeon that there was a secondary and inoperable growth in the sternum itself. Subsequently the patient had x-rays applied a few times and received some injections of what was probably a culture of *M. neoformans*.

Finally, in November, 1907, he placed himself in the hands of the writer of this note, who commenced the special treatment in question. It was continued until May, 1908, at which date all evidence of new growth had disappeared, and the patient was apparently in perfect health, locally and generally. That is still the position at the date of writing, eight months later.

In describing these cases it has not been thought necessary to enter into finer details of their clinical course, but their more essential features are all duly recorded. It is conceivable, of course, that in Case I the growths seen and deemed by the operator to be malignant and inoperable may have been tuberculous. Such cases do occur, but it

would be a strange coincidence if one followed a previous operation for cystic disease of the ovary. In the other two cases the initial disease was verified microscopically, and, as in the first case, the recurrences were deemed by surgeons holding positions on the senior staff of important London hospitals to be malignant.

I propose to report the conditions of these three patients again a year hence, whatever it may be.

The treatment employed was the injection of a solution of hypochlorites of potassium and sodium. This I prepare by dissolving 5 grams of KOH and 4 grams of NaOH in a litre of distilled water, and passing it through washed chlorine gas. Of this solution, 1½ to 2 c.cm. were injected daily for a varying period, usually under the skin over the deltoid muscle or over the great trochanter, so that the solution might enter the system at a site in the general neighbourhood of the lymphatic glands. The growth itself and the skin over it were carefully avoided. So, too, was the use of alcohol during treatment. I use an ordinary all-glass syringe with a platinum needle (to avoid corrosion), and in making the injections adopt ordinary aseptic precautions. There is a varying amount of local pain, lasting for from two to five minutes. I have not seen any reaction.

Should any medical reader care to try the treatment and desire further details, they are, of course, at his disposition.

THE TREATMENT OF CANCER WITH COCAINE.

By ROBERT MUNN GILCHRIST,

BOLTON, LANCs.

THE first time I used cocaine in the treatment of cancer was as a local application in a very painful secondary case, the primary growth having been removed a few weeks before by the late Dr. McGill of Leeds. On its recurrence, I saw Dr. McGill along with my patient, and he at once came to the conclusion that further operation was out of the question. This was a very instructive case, as, being on the face, you could watch the progress of the growth under varying forms of treatment.

Before the use of cocaine, from the first indication of a fresh deposit until ulceration occurred was a period of about three days, but after the use of cocaine this period was lengthened to as many weeks, thus showing that cocaine had some influence in retarding the growth.

In July, 1891, discussing with my late friend, Dr. Calderwood, "the Mattei treatment of cancer," I said that the only agent I had ever used having any effect on the growth of abnormal epithelial tissue was cocaine, and having a very suitable case under my care at the time, I determined to try the effect of the internal administration of cocaine.

CASE I.

Mrs. C. was 49, and almost *articulo mortis*. Extreme anæmia, probably from secondary deposits in stomach and liver in this case of uterine cancer, had brought her into this condition. Having an idiosyncrasy to opiates, whichever way administered, made this case not a very easy one to treat, especially as she was suffering very much pain. I commenced the treatment with cocaine by giving her one-eighth of a grain every three hours, and gradually increasing it to one-quarter of a grain. The growth in this case occupied almost the whole of the vagina, and involved both bladder and rectum. She had excruciating pain, retention of urine, general anasarca with albuminuria, and most alarming attacks of hæmorrhage. The effect of the administration of cocaine was most marked and immediate. The hæmorrhage became less and less, the pain was very much relieved, the anasarca and albuminuria disappeared, sickness stopped, and she again began to take her food with relish.

She continued to improve for six months, when, being much upset by her husband, she had an attack of meningitis, from which she died.

CASE II.

Miss W. consulted me about her breast in May, 1891. I found a growth involving the whole of the left breast, and enlargement and induration of the axillary glands. The skin over the breast was becoming affected, and I advised immediate removal. To this she would not consent. I then commenced treatment by administering cocaine both internally and externally. The pain, which had been the most important factor, became to all intents and purposes a negligible quantity. The skin broke down in many places over the breast, but healed. The growth seemed to remain in a stationary condition, and the glands in the armpit, if anything, became smaller. She continued in

this way without any material change until December, 1892, when she died from an acute attack of phthisis.

CASE III.

Mrs. H., aged 52, came to me in July, 1891, with cancer involving the whole of the uterus. Her chief symptoms were pain and hæmorrhage. The general condition of this patient was very bad, as she had suffered for years from a large number of chronic ulcers on the legs. Here I again administered cocaine, with the result that the hæmorrhage at once ceased and the pain became a very unimportant factor. She improved very much constitutionally, and was able to walk a mile from home a week before her death, which took place in April, 1892, from obstruction of the bowels. She would not consent to operation.

CASE IV.

N. C., aged 38, came under my care in November, 1891. I found a cancer involving the entire lumen of the rectum. He had great pain and difficulty in passing his stools, which act was always accompanied more or less with hæmorrhage. He continued under my treatment for about ten months, during which time he gained slightly in weight, and had very little pain. The hæmorrhage ceased, and the growth seemed to be stationary, as also to become more regular in outline to the touch. Because I could not promise him a definite cure he placed himself in the hands of a quack. He quickly got worse and died.

CASE V.

Mrs. M., aged 50, had cancer in the left breast. The growth was about the size of a pigeon's egg, and the skin was adherent to it. The nipple was retracted, and the axillary glands hard and enlarged. She commenced taking cocaine in September, 1892, and continued until July, 1893, when I amputated the breast and excised the glands. During the six months she was taking the cocaine the growth seemed sometimes to be a little smaller, sometimes a little larger—in fact, correspondingly as she took the cocaine. I have lost sight of this case.

CASE VI.

Mrs. B., aged 47—a case of uterine cancer—came under my care when in a very advanced state. She was shrunk and shrivelled, and had most marked cachexia. In this case also the hæmorrhage ceased, and the pain was very much alleviated. She died after ten months' treatment.

CASE VII.

Mrs. W., aged 43, came to me in April, 1892, with advanced cancer of the left breast. She had the six large breasts. The growth involved the entire breast; the skin was affected, and the glandular enlargements in the axilla were very marked. This case improved less than any other in which I have administered cocaine, and she died in October, 1892. The treatment at first seemed to stay the growth; but sloughing commenced, and, if there was any peculiarity, it was the size of the sloughs that kept coming away.

CASE VIII.

Mrs. E., aged 43—another case of advanced uterine cancer—came under my care in August, 1893. Here again the cocaine has controlled the hæmorrhage, and there is no other symptom of the growth present besides a sensation of weight. The more cocaine she takes the better she is, and she is performing her household duties.

CASE IX.

Mr. W. This was a case of some malignant disease involving the pyloric end of the stomach. Opiates failed to give any relief to his suffering, so I administered cocaine, from which he had considerable benefit. He died suddenly after three or four months' treatment.

CASE X.

Mrs. B., aged 47, had considerable swelling in the right breast, with enlargement of axillary glands. She had the usual pains. After four months' treatment the enlargements have entirely disappeared, and she is now in her usual health.

CASE XI.

Mrs. C., aged 42, had also swelling in the right breast, with pain and enlargement of axillary glands. After two months' treatment the breast has returned to its normal condition, and she is now in her usual health.

CASE XII.

Mrs. R., aged 37. A similar case to Case XI. Here again the symptoms have disappeared under treatment.

CASE XIII.

Miss H., aged 35, had swelling in the left breast, with pain and enlargement of axillary glands. Under treatment with cocaine all the symptoms have disappeared, and she is now in her usual health. The mother of this patient died some years ago from cancer.

CASE XIV.

Mr. B., aged 50. Seven years ago I removed an epithelioma from his lower lip. Some months ago he consulted me as regards a whitish-looking blister which had come on the site of the cicatrix. I gave him cocaine both internally and externally, and the lip has resumed its normal appearance.

In all these cases the administration was followed by benefit.

1. In every case the general constitutional condition of the patient was very much improved, even if that was only for a time.

2. From the observations I have made in these cases, I consider, so far as the relief of pain is concerned, that cocaine stands unrivalled, for while easing, or altogether taking away pain, we have none of the objectionable conditions which opiates produce.

3. In every case of uterine cancer where hæmorrhage was a prominent symptom the administration of cocaine was followed by immediate benefit; either stopping the flooding entirely or leaving only at intervals a show.

As to the *modus operandi* of the drug I offer no opinion. The cases cited show the general improvement in health, the relief of pain, and the power of controlling hæmorrhage. Whether it has any power over, or effect on, the embryonic epithelial cell, whereby a malignant is converted into a benign tissue, or whether its action is on the nerve terminals, or whether it is only by its powerful stimulating action generally, that cocaine has any control over the symptoms mentioned I do not know, but I know that patients suffering from cancer bear larger doses of cocaine with impunity than is generally understood, looking as if there was some natural affinity between the one and the other.

If a patient came to me suffering from a growth in which the diagnosis was doubtful, I would administer cocaine, and if there was then no improvement I could almost certainly say the growth was not malignant. So that I consider cocaine also a valuable diagnostic agent.

Reverting again to the cases mentioned, I may say that I cannot trace Nos. 5 and 8; No. 10 died last year from bronchitis, and Nos. 11, 12, 13, and 14 are still living and have not had any recurrence of the disease.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CANCER HOUSE.

It appears to me that the following facts may be of some interest to your readers.

Some short time ago a man came into my consulting room one evening. He had tuberculous glands in his neck, and in trying to elicit a family history he gave me the following remarkable and interesting account.

His family lived on a farm in Glamorganshire. The house is old, and at one time had been of considerable size, and occupied by the agent of the property on which it was built. Latterly this house had been divided into two smaller houses by a partition wall, each house being occupied by a family of farmers, who were not related to one another—the T.'s, my patient's family, on one side, the R.'s on the other.

Mary T., the farmer's wife, suffered from cancer of the stomach, from which she died at the age of 76 in 1882.

Her daughter-in-law, Emma T., lived in a farm near by, and who nursed her in her illness, moved with her family into the house on the old woman's death. She was operated on for cancer of the breast in 1886, which recurred, and from which she died in 1890 at the age of 49.

Her daughter, Edith T., nursed her mother in her last illness, and she in turn developed cancer of the breast, which returned after operation, and she died from the recurrence in 1896 at the age of 32.

Edith T. was nursed in her last illness by Mrs. R., who lived in the other half of the divided house. Mrs. R. died in 1900, aged 68, from cancer of the breast.

Her husband's nephew, David R., came to live at the farm after Mrs. R.'s death, and he died there in 1903, at the age of 32, from cancer of the throat.

We have here a series of 5 fatal cases of cancer under one roof, if not actually in one house, in a period of twenty-one years, and only two of these persons were blood relations—Emma and Edith T., mother and daughter.

It seems there is something more than coincidence here, and that probably there are predisposing, if not determining, factors to be found in the house and its surroundings. The house is built on the side of a stream that courses down the valley. The stream, which is often swollen with floods, is not sluggish, but the subsoil is always saturated with moisture. The valley is thickly wooded, and many trees are affected with arboreal

tumours, one tree, an ash, close to the house, being much disfigured by these bosses.

Mr. Keith W. Monsarrat, in the *Medical Annual* for 1899 and 1900, summarizes the views of Haviland, Noel, Fiesinger, Lloyd-Jones, and others, that cancer is most prevalent in low-lying districts, near rivers which are liable to floods, and that proximity to trees is connected in some way with the prevalence of the disease. The connexion between the prevalence of cancer and the prevalence of arboreal tumours has also been noted by many observers. These vegetable tumours are apparently contagious, as several usually exist on neighbouring trees, and it is supposed that the infection is borne from tree to tree by insects.

ROBERT J. SIMONS, M.R.C.S., L.R.C.P.

Bridgead, Glamorgan.

RUPTURE OF THE VENTRICLE.

I was called to see a man, aged 80, who had been found dead in bed. He had been quite well previously, and had been heard moving about half an hour before he was found. There were no signs of any struggle.

At the *post-mortem* examination the pericardium was found to contain 4 oz. of fluid blood and 8 oz. of clot. The heart weighed 20 oz. On the front of the left ventricle was a zigzag rupture, $\frac{3}{4}$ in. long, communicating with the interior of the ventricle. All the valves were atheromatous, especially the aortic and mitral. There were large calcareous plaques in the aortic valve. The heart muscle was hypertrophied and showed extensive fatty degeneration. The coronary arteries were normal. The aorta and large vessels were atheromatous and calcified. The right pleura was adherent all round and the left pleura at the apex. The right lung weighed 2 lb. 1 oz., and contained a small old tuberculous focus at the apex. The left lung weighed 1 lb. 13 oz., and had a large calcified tuberculous nodule at apex. There were evidences of bronchitis and oedema throughout both lungs. The liver weighed 3 lb. 13 oz. and was fatty. The spleen was very hard and weighed 8½ oz. The kidneys weighed 6½ oz. each and showed chronic nephritis, with diminution of cortex and cysts both on the surface and internally. The capsule stripped easily. The bladder was in a condition of chronic cystitis, and the prostate was enlarged and cystic. The brain weighed 2 lb. 12 oz. The dura mater was very adherent to the bone. The basilar and other arteries showed marked atheroma.

Death was due to rupture of the ventricle, probably the result of some strain, such as coughing. I believe spontaneous rupture of the ventricle is a very uncommon condition.

London, N.

SIDNEY F. FOURCARE, L.S.A.

A CASE OF FOREIGN BODY IN THE PLEURAL SAC.

THE patient in the following case was a baby of 8 months, which when I first saw it on August 4th presented all the phenomena of severe right-side pneumonia, and in addition an incessant short-cough.

Progress.—During the next few days its condition oscillated, and on the 9th I found evidence of pus in the right pleura, though much of the dyspnoea was gone. As I was going away early next day, I asked my locumtenent to place the case first on his list and visit it, prepared to operate if need be.

Treatment.—This he did, and, my partner, Dr. H. W. Garden, administering chloroform, incised the swelling which I had located and let out a little very fetid pus. A drainage tube was inserted and kept in till August 22nd, the child meantime improving somewhat. Three days later, having returned home, I reassumed charge of the case. I found the cricoid of the sinus inflamed, the surrounding tissue oedematous, and a little non-offensive pus exuding. On passing a probe a spot was felt which suggested bare bone, but did not feel quite like it.

Result.—About a week later, during which the child's condition improved somewhat, I noticed, when about to dress the case, a little brown spot in the wound not larger than the point of a blunt pin. I seized it with forceps and drew out a body about 1½ in. long and as thick as the lead pencil supplied with pocket-books. It was soaked with pus, and a little offensive. After carefully washing it I thought at first it was a piece of a sweeping broom, but on more minute examination I recognized it to be a spike of the common meadow barley, *Hordeum pratense*. The spike was quite perfect. The next day the child was vastly better, the wound had taken on a healthy appearance, and in ten days the wound was healed and the child quite well.

REMARKS.—It seems incredible that a baby of this age could have sucked a body of the size and shape stated into its larynx, and that this should have passed down the right bronchus, worked its way through the base of the lung, and finally into the pleura, whence it was removed through the chest wall. On the other hand, if the body were swallowed and passed up from the stomach through the diaphragm into the pleural cavity, the dyspnoea, stridor, and symptoms of pneumonia could not be explained. The mother could throw no light on the affair. One whole day the child had been out of her sight and in the care of a neighbour, but this woman denied having given the baby any grass stalks to play with, and I could elicit no history of sudden spasm or partial asphyxiation, such as one would expect to occur when the foreign body passed the epiglottis.

Chadwell Heath.

T. RECELL ATKINSON, M.D. Durh.

VARICELLA AND HENOCH'S PURPURA.

THE two following cases exemplify certain morbid relations:

CASE I.—In December, 1907, D. B., a girl of 7, recovering from varicella, began to suffer from pain and swelling in the larger joints. Salicylate of sodium was prescribed, and in two days these symptoms abated, to give place to vomiting and abdominal pain, tenderness, and distension. Treatment gave little relief until, after several days, blood began to appear in the evacuations. The heart was now found to be affected, and exocardial and endocardial murmurs were audible at base and apex. Coincidentally there was a return of arthritic pain, and about wrists and ankles appeared an eruption of purpuric spots. There was no renal nor other complication. Recovery was slow, and a cardiac bruit persists. The child was fair, of delicate appearance, defective teeth, motherless from early infancy, without evidence of past tuberculosis, but exhibiting in her stature and gait (congenital) dislocation of both hips, a state confirmed by skiagram.

CASE II.—A. W., a boy of 2½ years, had pertussis and bronchopneumonia in March, 1908, and by June had only partially recovered, when he, with other members of the family, were attacked by varicella. The lesions were of the usual distribution, the severest those on the belly, where an intense red aureola surrounded each, and where into each vesicle haemorrhage had obviously taken place. Above the knees and on the arms were several subcutaneous ecchymoses. The boy was very sick and in constant gastric pain. The abdomen became swollen; the surface around the varicella lesions oedematous, tender to palpation. An intestinal haemorrhage was predicated; it appeared after several days of constipation. The vesicles soon began to slough, and so deeply as to expose the muscles—varicella gangrenosa. Haemorrhage ceased; the abdomen, however, continued to be swollen, the inguinal glands enlarged, and when the boy was well enough to run about, and the family removed to another town, he still presented the picture of tuberculous peritonitis. This patient had not been vaccinated, as his mother attributed the death of an earlier child to the severity of vaccinia.

REMARKS.—The two cases illustrate the play of related morbid processes—the infective and the rheumatic, the rheumatic and purpuric, purpuric and tuberculous.

Clifton.

DAVID A. ALEXANDER, M.B.

THE TREATMENT OF CHILBLAINS BY PEROXIDE OF HYDROGEN.

SINCE 1903, when Dr. Norman Walker quoted Courtin of Bordeaux (in the *Medical Annual*) as originating this treatment, I have frequently employed it, and have been greatly pleased by its almost unvarying success. My plan is for the patient to bathe the affected parts in peroxide of hydrogen (10 vol. strength), diluted with equal parts of previously boiled water, still hot, for fifteen or twenty minutes, twice daily. This treatment has the additional advantage of being capable of being carried out even if the chilblains are cracked and ulcerated, though it is well to diminish the strength of the peroxide if much pain and irritation is produced by the application. A continuation of this treatment for two or three days in most cases will effect a cure.

Lincoln.

E. MANSEL SYMPSON, M.D.

DIACHYLON AS AN ABORTIFACIENT.

DR. EDMUND HAY's interesting memorandum in the JOURNAL of January 23rd, p. 214, giving an account of three cases of plumbism due to the taking of diachylon to procure abortion, calls attention to the somewhat curious fact that hitherto London seems to have escaped this evil, which has spread so widely in the populous centres of the Midlands. Thanks to one or two sentences of hard labour upon midwives, who were proved to have sold these "diachylon pills" for improper purposes, there appear to be somewhat fewer cases in the districts about here. Cases still, however, occur from time to time. Only last month I saw one which ended disastrously. Its history is briefly as follows:

A young single woman, aged 23, the daughter of highly respectable parents living near Sheffield, was brought to my consulting rooms by her parents, on account of great weakness and very severe headache. She looked extremely anaemic and very ill. On examining her chest, I found the breasts full and tense, with a small quantity of secretion from the nipples on pressure. Further investigation showed the uterus reaching to the umbilicus. An amenorrhoea of about six months was admitted. On looking at the gums, I found a deep blue-black border. Everything was denied by the patient herself, both the possible pregnancy and the taking of diachylon. However, I pointed out to her parents the gravity of the symptoms, sent her back home, and urged them to call in their own medical man at once. I wrote to him explaining the position of things, and two days later I received from him a letter, saying that he had been hastily summoned to the patient the day before to find she had been delivered of a dead fetus whilst at stool. Unfortunately that is not the worst. One month later he telephoned, asking me to go over at once and see the girl with him. She was then in the last stage of cardiac failure secondary to subacute nephritis. The headache had been agonizing. There was double optic neuritis, with extensive haemorrhagic retinitis; vision almost gone; the blue line was still very marked, and she was in extreme distress from dyspnoea. In fact, her condition was quite hopeless.

It seems that she had suffered from albuminuria for some years previously, so that the effect of the diachylon on the already impaired kidneys was doubly severe.

With cases such as the above coming under observation, it does seem that some steps should be taken to put a stop to this evil. So far it has been found impossible to move the authorities in the matter. In spite of much trouble and many meetings, with strong resolutions passed, urging the desirability of putting diachylon on the poisons schedule (as is ergot), we were informed that, acting upon "expert" advice, they considered that it was unnecessary. I can only say, "*Ne crede Experto!*"

I am satisfied that the simple procedure of putting diachylon on the poisons schedule nobody would be the loser, and on the other hand the evil we suffer from would soon die out, at any rate in its present form.

As it is, no respectable chemist in the affected districts sells diachylon without pointing out its dangers, and the disreputable people who trade in it, knowing the purpose for which it is being purchased, require checking. By scheduling it as a poison such a check would be provided.

Should this scourge extend largely in London it is possible that adequate pressure may be brought to bear upon the authorities to do something; hitherto, the provinces have failed to stir them.

Sheffield.

ARTHUR J. HALL, M.D., F.R.C.P.

A METHOD OF TREATING EXCESSIVE AXILLARY SWEATING BY OPERATION.

This condition is very common and is a source of very great discomfort to those who have to work in hot climates, wearing tight clothing.

About three years ago an army surgeon was unfortunate enough to contract septicaemia while operating, and eventually had to suffer extensive loss of his left axillary glands. Owing to sinuses it was necessary to excise a large portion of skin, and when he recovered he noticed that he no longer sweated from this axilla. Investigation showed that the whole of the hair-bearing skin of the axilla had been removed, and with it the large sweat glands as well.

The contrast to the other axilla was so great that, being under orders for service on the West Coast of Africa, he determined to have something of the same kind done to the right axilla. Under eucaïne and adrenalin the whole of the hair-bearing skin was excised, and now he has two non-sweating axillae.

The operation is very simple, quite painless, does not entail opening the axilla, and is free from risk. If careful suturing is carried out the incision heals by first intention, and the arm can be used in a week or sooner if necessary. This may appear rather a drastic method of treating hyperhidrosis, but it is satisfactory and radical. Ordinary measures were quite useless, and the officer now regrets that he did not know of this method of cure before.

MEDICAL SOCIETY OF LONDON.

Monday, January 25th, 1909.

CHARLES BARRETT LOCKWOOD, F.R.C.S., President,
in the Chair.

Wertheim's Operation.

DR. COMYNS BERKELEY read a paper on the radical abdominal operation for cancer of the cervix by Wertheim's method. Wertheim modified the original operation by clamping forceps across the vagina before he divided this structure, and since he had performed the radical abdominal operation more consistently and in a larger number of cases than any one else, this operation had, at any rate in England, been attributed to him. Dr. Berkeley had collected full statistics of 229 cases of the true Wertheim operation from different operators in the United Kingdom. He pointed out that Wertheim's operation had a great advantage over simple vaginal hysterectomy both in its percentage operability and percentage of cures, whilst if only similar cases were taken there was not much difference between the primary mortality. The primary mortality for simple vaginal hysterectomy with Continental operators was on an average about 9 per cent. Doderlein gave a table of 4,368 vaginal hysterectomies with a mortality of 9.1 per cent. The mortality for Wertheim's operation in early cases worked out at 6.8 per cent., in moderate cases 8 per cent., and in advanced cases 26.7 per cent. The mortality of the 229 Wertheims which he had collected was 18.3 per cent., the mortality of his own cases was 16.6, of Wertheim's 458 cases 15.2. The primary mortality, taking all the cases, was high, but the statistics showed that this death-rate was considerably lowered with the increased experience of the operator; in Wertheim's first 30 it was 40 per cent., in his last 30, 7 per cent. The high mortality when compared with simple vaginal hysterectomy was entirely due to the fact that cases of a much more advanced nature could be operated upon with safety by Wertheim's method. The percentage operability of vaginal hysterectomy was about 12. In comparison with this a large number of operators had a percentage operability of 40 and over. He (Dr. Berkeley) and Dr. Bonney had kept careful record of all cases of cancer since they commenced operating by Wertheim's method, and their percentage operability to date was 67. Although vaginal hysterectomy might have a low primary mortality, the after-results of this operation were disappointing. Waldstein out of 274 cases had 4 living after five years, and the statistics of other operators gave similar results. As the Wertheim operation had only been performed in England, with the exception of a case by Wallace in 1903 and one by Spencer in 1904, since 1905, the statistics as to the percentage of cures were at present of no use, as five years was regarded as the shortest limit for that purpose. Of 200 cases that Wertheim had operated upon more than five years ago, 138 were still living, a percentage of 62. Polossan had 60 per cent. and Bumm 30 per cent. living free from recurrence after five years. That increased percentage of cures was due to two factors. By Wertheim's method the parametrium and cellular tissue could be removed, whereas in vaginal hysterectomy it had to be left behind, and Wertheim's clamps prevented local cell implantation. Dr. Berkeley discussed the pathological findings of the parametrium and cellular tissue in cases of cancer of the cervix, and showed that it was infected with cancer in 60 per cent. of the cases. He also discussed the question of local recurrence and cell implantation, and showed that by the extended abdominal operation local recurrence was rare. In comparing the operation of para-vaginal section with Wertheim's operation, Dr. Berkeley

thought the chief decision as to which was the best method must rest upon the question whether it was necessary in Wertheim's operation to remove the regional glands. If the glands that could be surgically removed were diseased, in a large number of cases those which could not be removed were also diseased, and many operators said that for that reason it was useless removing any glands, and in favour of that contention was the fact that glandular infection was not present in probably more than one-third of the cases. Some statistics from the Middlesex Hospital Cancer Investigation Laboratories strikingly illustrated that point. Supposing there were no need to remove the glands, then the advocates of para-vaginal section contended that by that operation just as much parametrium and cellular tissue could be removed without so much danger to the patient. In Shauta's hands, who had probably had more experience of that operation than anyone else, the results were good, the total mortality for 258 cases being 10.8, and in 79 early cases 3.7. His percentage of cures over five years had been 55, and his percentage operability had been nearly as great as those who operated through the abdomen. Dr. Berkeley showed a special pair of clamps which entirely overcame the difficulties and dangers associated with Wertheim's clamps. He also showed 27 of the 30 specimens that he and Dr. Bonney had removed.

Dr. SPENCER thought the authors had not fully stated the low mortality of vaginal hysterectomy. Some operators had had a lower mortality from vaginal hysterectomy than that stated in the paper. The most terrible thing about the operation was the high mortality—Wertheim's first 200 cases showed a mortality of 24 per cent., and in the 400 9 per cent. After vaginal hysterectomy the mortality was not more than 4 per cent. or 5 per cent. It was a very serious thing to submit a patient with early cancer to such a formidable operation. One great drawback of the operation was that the woman was unfit afterwards for intercourse, whereas, after vaginal hysterectomy, she could not only continue to have connexion, but her feelings were retained. He criticized the method of rendering hospital operability statistics. A fairer method would be to state the total hospital statistics. It would be interesting to see what would be the result in the patients mentioned in the paper after an interval of five years.

Dr. McCANN thought the future of the operation lay in its application to early cases. He had great doubts whether that or any operation was of value in advanced cases. At first he did the operation only on advanced cases, and the cases occurred rapidly. If the operation were applied to early cases he believed the mortality would be as low as that of vaginal hysterectomy. A very important point was ensuring hæmostasis and careful covering of the surfaces of the peritoneum. If those matters were not carefully attended to there was likely to be subsequent infection. If they were attended to, even if the bladder leaked or there was a rectal fistula, the patient might survive. It was his practice to keep the patient in the Trendelenburg posture for as short a time as possible, examining the patient's pelvic organs before having her put into that position. He agreed with Dr. Spencer that the present method of rendering percentages of operability was absurd. Where the bladder was involved the operation was not justifiable, in his opinion. He had never kept a drain in longer than forty-eight hours, and if hæmostasis was sufficiently established it was not necessary to put in a drain at all. If the bladder was regularly emptied after the operation cystitis would rarely occur.

Dr. LEWERS was very firmly convinced of the value of the operation, and that it would be the operation not only for cancer of the cervix, but also for the body of the uterus in the future. Up to the present he had done the operation twenty-two times. Out of his first ten he lost four, but in the second ten none at all. In all the cases in which he did it the condition of cancer was advanced. In the majority of the cases he thought the operation must be commenced as an exploratory laparotomy, because in some it was not possible to go on to finish the operation.

Dr. RUSSELL ANDREWS said his experience was very similar to that of Dr. Lewers. He had had very few opportunities of dealing with early cases. He believed the mortality from the operation, when it was properly

understood, should not be higher than from vaginal hysterectomy.

The meeting concluded at a late hour with the reading of a paper by Mr. W. F. BROOK (Swansea), entitled, "A preliminary note on the relationship of delayed union in fractures to deficiency of calcium salts in the blood."

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Friday, January 8th, 1909.

JOHN LENTAGNE, P.R.C.S.I., President, in the Chair.

Extroversion of the Bladder.

MR. C. ARTHUR BALL, in a paper on the treatment of extroversion of the bladder, expressed an opinion that the safest and most satisfactory procedure was the transplantation of the ureters into the rectum by an extraperitoneal operation, and gave a lantern demonstration of a case in which the operation had been carried out in a boy aged 5 years. The child was operated on last July, and the result was satisfactory, the child being in perfect health six months later, and having very fair powers of retaining urine in the rectum. Three months after the operation urine could be retained up to three and a half hours, and this control had continued to improve since then. The PRESIDENT said the case was, so far as he knew, the first satisfactory one that had been done in Dublin, and illustrated the improvement which had been effected in dealing with an apparently hopeless condition. He desired to know whether it had been proposed to infold the rectum at the point where the ureter entered it, so as to make it less likely to slip out, and give a broader field for adhesion on the part of the ureter. Mr. SETON PRINGLE asked if there was any trouble in keeping the peritoneum back, and in seeing what was being done. Mr. BALL, in reply, said he did not think infolding of the rectum had been done. In his case there seemed to be no tendency to slip out. He did not see the peritoneum until he first came on the rectum. One would have expected it to get in the way sooner that it did. There was considerable separation of the pubic bones, and the pelvic cavity was consequently very shallow, so that the case was ideally arranged for the surgical procedure carried out.

Abscess of the Pancreas.

Mr. SETON PRINGLE gave an account of the case of a patient, aged 46, with a marked alcoholic history, who was admitted to hospital on the twelfth day of his illness with signs of peritonitis of the upper abdomen, where a large tumour mass could be felt. Operation was performed immediately, and a large abscess found in the lesser peritoneal sac; the edges of the opening into the abscess were sutured to the parietal peritoneum and a large drainage tube inserted. There were numerous patches of fat necrosis in the omentum, and a small quantity of bloody fluid in the larger sac of peritoneum. The patient progressed favourably for a few days, but gradually lost strength and died on the twelfth day after operation. The urine several days after operation gave a marked Cammidge "C. reaction." At the *post-mortem* examination it was found that the head and body of the pancreas had sloughed, only the tail surviving; no gall stones were discovered. He considered that the pancreatitis in his patient was the result of alcoholic gastro-duodenal catarrh. Only some 16 cases of operation for pancreatic abscess had been recorded. The PRESIDENT said that cases of comparatively newly-recognized diseases, the symptoms of which were most obscure, were just such as should be brought forward in detail as by Mr. Pringle. The case showed the importance of early operation. If the abdomen had been opened at an early stage it was possible that the gangrene might have been averted; at any rate, it would have been more hopeful. It was only by the bringing forward of such cases that they would be able to arrive at an early diagnosis. Mr. STOKES said he had seen a similar case operated on a couple of years ago, in which acute septic peritonitis was found at the *post-mortem* examination. But for that the case might have pulled through. The question of draining behind had been raised, but the Americans had given that up unless the inflammation were confined to the tail of the pancreas. Mr. BALL suggested that the apparently greater frequency of the disease in hospital patients than in private patients might arise from differences of habits in eating and drinking.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

At a meeting on January 26th, Sir LAUDER BRUNTON, F.R.S., in the chair, a discussion on *Ulcerative colitis* was opened by Sir WILLIAM ALLCHIN, who, after referring to the comparative infrequency of the condition, its age and sex incidence, alluded to 177 cases collected from the case records of three of the larger general hospitals in London. He then referred to the influence, if any, of previous residence in a warm climate, with especial reference to the form of sporadic ulcerative colitis usually classed as dysentery, and to its relation with chronic interstitial nephritis. He next gave an account of the clinical features of the disease, its duration, liability to relapse, and event. The mortality was distinctly higher than in tropical dysentery, but the prognosis in any particular case was very uncertain. The *post-mortem* appearances were described. The influence of one or other form of *Bacillus dysenteriae* was discussed, the speaker maintaining that the evidence was adverse to the microbiotic identity of the sporadic and epidemic disease. The causative influence of tissue vulnerability in certain cases was referred to, and lastly the methods of treatment—medicinal, by enemata, surgical operation, or by the use of serums and vaccines. Mr. MAKINS, referring to its surgical treatment, argued for a simple colostomy, preferably in the ascending colon. Appendicostomy not diverting the intestinal contents was much less useful. Of 6 cases in which he had done colostomy, only 1 was really cured, but only 1 died. The contraction of the bowel after colostomy for ulcerative colitis was, however, a much more serious matter than after that performed for other conditions. If the artificial anus were left open more than seven or eight months, the re-establishment of the normal channel was a very difficult matter; indeed in some instances it was necessary to maintain the artificial opening for life. Dr. HALE WHITE thought ulcerative colitis quite distinct from tropical dysentery. As to its identity with asyrium dysentery he thought the matter was not proven, and he pointed out that its prevalence was much greater than in institutions other than asylums, suggesting that some influence of the nervous system was involved. Reference was made to the causation of ulcerative colitis by the bursting of a liver abscess into the intestine. He likewise condemned short-circuiting in operative treatment and could not speak favourably of rectal irrigation or the use of drugs. Three cases had come under his notice during the last year that had apparently recovered under the use of a coli vaccine and artificially soured milk. The discussion was then adjourned until February 10th at 5.30 p.m.

SECTION OF ANAESTHETICS.

At a meeting on January 20th, the bill by which it is proposed to control the administration of anaesthetics (see SUPPLEMENT, BRITISH MEDICAL JOURNAL, December 5th, 1908, p. 502), was discussed, Dr. DUDLEY BUXTON proposing that Clauses I, IV and V, be approved, and also Clause III if amended so as to read:

This Act shall not apply to any person registered under the Dentists Act, 1878, who shall administer nitrous oxide gas with the object of producing a state of unconsciousness during any dental operation, act, or procedure.

Dentists, he said, always had been recognized as proper persons to administer nitrous oxide gas, and this right should not be taken from them; but that they should be prohibited from administering the more dangerous anaesthetics unless they possessed a medical qualification in addition to their dental one. Mr. ROWLAND COLLUM said that the amendment proposed was essential in order to make the bill fair; for, by another clause, dental students were to be forced to receive thorough theoretical and practical instruction in anaesthetics; and yet by this clause, unless amended, they would be liable to a fine if they ever administered one afterwards. Dr. SLK opposed the whole bill on the ground that legislation was not the proper way to bring about the required result. The House of Commons would never pass such a bill. Dr. HEWITT said the safety of the patient should be the first consideration of every medical man. It was not right that a dentist should be permitted to administer even nitrous oxide gas. A medical training was essential to the safe administration of any general anaesthetic.

Mr. PREEDIE pointed out certain errors that some of the speakers seemed to him to have made in their interpretation of the bill, for the wording of which he was responsible, and the meeting was adjourned to February 5th.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—At a meeting on January 15th, Dr. WALKER DOWNE, President, in the chair, Dr. W. B. INGLIS POLLOCK read a paper on *Nystagmus, and theories regarding its causation*. Opening with a brief account of the searching nystagmus of Sym, the pseudo-nystagmus of Duane, and true nystagmus, the latter was divided, according to its causation, into congenital, occupational, organic, nervous disease type, labyrinthine, and toxic, including the general anaesthetics, ether and nitrous oxide, ether and nitrous oxide and oxygen. A short description was then given of the various theories of the mechanism of nystagmus. Duchenne ascribed it to a retardation of the nervous impulses to one member of a system of antagonized muscles, while Widmark associated it with a want of harmony between the centre for the co-ordination of the ocular muscles and the volitional impulse. Gowers had recently brought forward a theory based upon Sherrington's researches into the spinal centres and the alternate contraction of opposing muscles. He believed that the centre for the control of the ocular muscles might be disturbed by influences from many sides, allowing a reciprocal muscle-reflex alternation between antagonistic ocular muscles to be set up. The paper was illustrated by a case of congenital pseudo-nystagmus, a case of congenital nystagmus due to high refractive error, and a case of miner's nystagmus with the vertical variety in one eye and rotational in the other. Dr. JAMES F. GEMMILL gave a lantern and microscopic demonstration of the auriculo-ventricular muscular bundle of His in the adult human and in certain fetal hearts. Dr. JOHN M. COWAN demonstrated a series of tracings of the venous pulse, illustrating the different conditions which may result from interference with the auriculo-ventricular bundle of His.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a meeting held on January 6th, Dr. P. BOORBYER, President, in the chair, a discussion took place on *The attitude of the municipality to the treatment of phthisis*. Dr. A. FULTON, in opening the debate, argued in favour of municipal sanatoriums, which, apart from curative and philanthropic influences, had a great educational value. Nottingham was so rich in medical charities that there was no need for extension of municipal treatment in the direction of further out-patient departments or dispensaries. He did not think the establishment of additional sanatoriums would injure the medical profession financially, for the richer class of patients would not be likely to avail themselves of such institutions, while the profession generally would be glad to be excused a long and profitless attendance on the poorer ones. The admission, treatment, discharge, and after-care of patients should be in the hands of some expert devoted to this purpose. It might even seem right to subsidize patients for some time after their discharge rather than let the benefit received be undone again by insufficient food before their proper earning powers came back again. The President traced the statistical mortality from tuberculous diseases and phthisis in the past and at the present time, showing that the general death-rate both of tuberculosis and phthisis had now been halved as the result of general sanitary improvements in the course of the last half-century. Of men and women engaged in the same class of work in the lace trade, the phthisis-mortality was very much heavier amongst the men, probably as a result of their more intemperate habits. He pointed out also what could be done by local sanitary authorities in the matter of preventive action, especially when aided by notification and personal teaching from expert health visitors. Dr. F. H. JACOB insisted on early examination of sputa before physical signs became obvious if cure was to be brought about. He thought it better for the serious cases to be isolated in municipal sanatoriums, and urged the need of house disinfection with every change of tenancy. Dr. C. H. CATTLE thought the results of the experiment of opening forty beds to phthisis patients at the Nottingham Isolation Hospitals

had been more successful than might have been anticipated. Besides great benefit to early cases such an institution sheltered many cases of which the home nursing sooner or later broke down owing to the heavy demands upon the strength, the rest, the food and the purses of relatives in their own houses. At the same time the present provision for forty beds was quite inadequate and might easily be filled even if increased to ten times that number. Dr. W. TIBBLES did not favour further extension of municipal sanatoriums, for the ultimate results of such treatment were not as good as was at first supposed. He thought the urinary, intestinal and other infective forms of tuberculosis should be guarded against quite as much as phthisis. Dr. W. HUNTER was on the whole satisfied with the preventive methods at present available in the homes of patients, and considered the expense of any further considerable extension of the sanatorium system at the expense of the ratepayers would be great enough to make it absolutely prohibitive. Dr. A. J. SHARP drew a graphic picture of the appalling mortality still due to tuberculosis in towns, about 450 deaths from it occurring annually in Nottingham alone, those dying being mainly persons in the middle and most useful age-periods of life. Notification came first and foremost of all preventive measures, and till that had been adopted no sanitary authority had at all realized its responsibility with regard to this disease. Dr. O. K. WRIGHT instanced the great educational value of sanatorium treatment even on the limited scale adopted by the Nottingham Corporation; despite the most inclement weather, he had found patients became readily acclimatized to fresh air in the course of a very few days. Miss I. E. FOX (Mansfield) had noticed that the introduction of compulsory notification of phthisis in Sheffield had been accompanied by very little friction. Actual instances of phthisical subjects infecting their co-workers in offices had come under her notice at Sherwood Forest Sanatorium. Dr. J. WATSON again urged the importance of early examination of sputum, and thought that any municipal scheme should give facilities for examination of sputum from people who had not placed themselves under medical care. Dr. FULTON, replying, attributed the stationary mortality from tuberculosis in Ireland partly to inherent poverty and partly to withdrawal of many of the fittest subjects by emigration. Phthisis in Nottingham at the present time was a burden the expense of which was not borne by the public, but by wives and relatives, who toiled to keep their homes together until they themselves broke down usually with the same complaint. The PRESIDENT detailed the methods of house disinfection now utilized in Nottingham. He was grateful for any recognition of curative value in the branch of sanatorium work under his direction, but, apart from the isolation of a few advanced cases, the main purpose of municipal sanatoriums was educative. Thus, in New York the average stay of each patient was only five weeks, or just long enough to get him well drilled in all matters of personal hygiene. As to the economic loss of lives, this was, to say the least, most serious. Indeed, it would be far cheaper to build sanatoriums and isolate as many patients as possible, for in that case the ratepayers would not be burdened with the maintenance of their bereaved and penniless dependents, as they were at present. After the conclusion of the discussion, a vote taken of those members present showed a strong and practically unanimous feeling in favour of voluntary or compulsory notification of phthisis being adopted.—At a meeting on January 20th, Dr. P. BOOBYER, President, in the chair, Mr. R. G. HOGARTH and Dr. R. HEELIS showed a man, aged 29, suffering from gigantic *Enlargement of the skull* and extremities, and from spinal kyphosis and other bony deformities. Up to the age of 12, when he broke one thigh, nothing abnormal was noticed, but about that time the upper jaw began to swell, and since then he had broken one humerus. His mental condition was normal, and although he sometimes had pain at the back of the eyes he seldom had headache. In spite of some features suggestive of leontiasis osseæ, the case as a whole seemed to accord better with acromegaly. Mr. HOGARTH showed a man, aged 40, employed as a caretaker, suffering from aneurysm of the innominate artery. Operation for distal ligation of the subclavian and common carotid arteries had been declined two years ago, but the disease appeared

practically unchanged since then. Mr. Hogarth also showed a girl, aged 10, who had suffered from multiple tuberculous lymphadenitis to a degree which made the condition inoperable. A few caseous glands were removed from the neck and systematic treatment with tuberculin in doses of $\frac{1}{1000}$ milligram carried out over a period of nine months. The result had been highly encouraging. Mr. R. G. HOGARTH read a short paper on certain *Derangements of the knee-joint* the result of traumatism. In the case of a young man under his care a movable lump within the joint proved on removal to consist of both articular cartilage and bone. Another case illustrated very well the "quiet necrosis" or osteo-chondritis desiccans which followed some injuries of this kind. A third case was in a young girl who, after recovering perfectly from an attack of acute synovitis lasting a month, relapsed. Eventually, after several attacks of slight synovitis, an operation resulted in the removal of a fibrous pedunculated body which took origin from the synovial membrane. Mr. Hogarth further traced the anatomical features of the joint concerned in the production of these injuries, and indicated occasional difficulties in locating and removing a loose body so produced, as well as the important relation the popliteus tendon bore in operations for their removal. Treatment by means of a steel bar hinged splint, which effectually prevented torsion, was recommended. Drs. R. WOOD (Ilkeston) and J. S. BOLTON discussed the paper. Dr. J. WATSON showed the placenta (single), fetal bags of membranes (distinct), and twins, of which one was living at birth and one previously dead, from a case of extreme hydramnios in a young married woman.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—

At a meeting on January 20th, Dr. SOLLY (Harrogate), President, in the chair, Dr. BUCKLEY (Buxton), in a paper on *Intestinal lavage* on the Plombières system, said that where evidences of intestinal putrefaction could be found from examination of urine, stools, etc., better results were obtainable by douching than by the use of chemical antiseptics, and in those cases where appendicectomy might seem to be indicated for lavage of the colon, this method should first be tried. Mr. WILLIAM ARMSTRONG (Buxton) said he had used intestinal lavage for the last eight years in a large number of cases. He reported in his paper in the "Arthritis" number of the *Practitioner* some six years ago a very remarkable case of rheumatoid arthritis cured by intestinal lavage alone. Certain cases of arthritis, many cases of urticaria, recurrent erysipelas, eczema, ordinary eczema, and neurasthenia had been greatly helped by this method. The important points had always seemed to him to be the exact indications for this treatment; and his experience had shown that the most reliable guide was the increase of the aromatic sulphates. Dr. ACKERLEY (Llandrindod Wells) asked if it was to be understood that the only treatment in the cases mentioned was intestinal lavage. On receiving an affirmative answer, he expressed his doubts as to the value of local treatment of the colon in securing permanent results in such cases. In all cases where there was a catarrhal or septic condition of the colon, treatment ought to be directed in the first place to guarding against oral sepsis and securing perfect mastication and insalivation of all kinds of food hard or soft. Removal of mucus by lavage had only temporary results. The secretion of mucus was protective, and the aim should be to prevent injurious substances entering or being formed in the bowel. In its proper place, as accessory to other treatment, he fully recognized the value of intestinal lavage. Dr. MOTTILOR (Harrogate) considered the method of intestinal lavage a most valuable addition to ordinary eliminative spa treatment. It was so even in Harrogate, where the waters usually act as laxatives. Dr. MANTLE (Harrogate) thought the theory of intestinal autointoxication might be carried too far; he was inclined to think with Hertz that it was necessary to have a breach of mucous membrane—an abrasion or ulcer—to get absorption of toxins from the bowel. He had found washing out the colon gave good results in some cases of rheumatoid arthritis and chronic skin diseases, but only when associated with colitis, and unless mucus was seen he would not advise it in such cases. Mr. C. R. B. KEETLEY said that appendicectomy or some such operation was a supplement to the Plombières treatment which might occasionally be found of utility.

Reviews.

AN OBSTETRIC DIARY.

A DIARY of the first three deliveries of Queen Charlotte, the wife of George III., has been edited by Dr. NIGEL STARK, and published under the title, *An Obstetric Diary of William Hunter*.¹ One thing that strikes us is the difference between the physician of 1762 and his successor of to-day. William Hunter, as most medical men know, was a man of much wider knowledge and greater refinement of intellect than his illustrious brother John, who, concentrating all his mind on anatomy and surgery, remodelled the methods of surgery for all time. William Hunter was a scholar, an anatomist, a numismatist, and a courtly gentleman. He was called in by Mr. Hawkins to advise as to Queen Charlotte, but he does not seem to have done much more than to listen to Mr. Hawkins and feel Her Majesty's pulse. Mr. Hawkins, like many of his contemporaries, seems to have thought that the sovereign remedy was bleeding, and Dr. William Hunter's chief service to Queen Charlotte during her pregnancy was to protect her from unnecessary depletion. He was not present at the delivery. This was supervised by the midwife, Mrs. Draper, not a person of very good judgement, for a little after 6 she told Dr. Hunter that "it would be slow," and at half after 7, "when I little expected it from what Mrs. Draper had told us, the Prince was born." Hunter waited in an anteroom. He examined the placenta and the "cloaths." He visited the Queen during the lying-in, felt the royal pulse, and prescribed some harmless carminatives. Almost the only thing that Hunter did that he could do better than Mrs. Draper was the examination of the placenta. It is curious to speculate what he would have done if his examination had led him to conclude that a piece of placenta or of chorion was retained *in utero*. Would the royal personages who did not allow him to supervise the birth of the infant have permitted him to explore the royal uterus and bring away retained placenta or chorion? We very much doubt it, and doubt if Hunter would have proposed it. His examination of the placenta doubtless interested him as an anatomist, but from a clinical point of view it was about as useful as the carminative draughts he prescribed. If a bit of retained placenta had led to haemorrhage or septic poisoning, and thus to loss of life, it would at that time have been said to have been a "visitation of Providence." What will be the duties of an accoucheur a hundred years hence? Anaesthesia will be expected by every mother as a matter of course; probably spinal anaesthesia. Will the ordinary general practitioner take his patient's opsonic index, and inject a few millions of dead bacteria, or will he call in a specialist, appointed by the local authority, to do this kind of thing for him? Whatever he does, we may be sure that by that time, if anything goes wrong, he will not be able to put the blame upon Divine Providence. We are told that "William Hunter had a talent for relating anecdotes with such facial and vocal expression that if he had adopted the stage as a profession he would have risen to high rank as a comedian." Considering the very limited obstetrical services that Hunter was allowed to render to his illustrious patient, it seems likely that his talent for amusing people had more to do with his success in practice than his professional skill.

GYNAECOLOGY

THE second volume of Professors KELLY and NOBLE'S *Gynaecology and Abdominal Surgery*² includes chapters on complications following operations, on the surgery of pregnancy, uterine and ectopic, and on the operative

surgery of the breast, liver, gall bladder and bile ducts, stomach, intestines, vermiform appendix, pancreas, spleen, kidney, and ureter; also other chapters on tuberculosis of the peritoneum, penetrating wounds of the abdomen, hernia, and the use of drainage in abdominal and pelvic surgery. This volume is of a high degree of excellence both as to text and illustrations, maintaining the well-approved character of the articles in the first volume, which was reviewed in the JOURNAL for March 14th, 1908. As we read so much about operations, we may feel inclined to turn, for a change, to the chapter on tuberculosis of the peritoneum, by Dr. George Ben Johnston of Richmond, Virginia. Had that article been written twenty years ago we should have found, we suspect, enthusiastic eulogies of operative measures; but Professor Johnston, like many other contemporary workers, is not enthusiastic about surgical treatment. He observes that Billings, A. E. Halstead, and Shattuck consider that in the ulcerative and fibrous forms of tuberculosis of the peritoneum the surgeon merely writes the death certificate, and adds that Ochsner states that a review of the literature of the subject has convinced him that surgeons who insist on thoroughness in operations for tuberculous peritonitis have had most unsatisfactory results. Dr. Johnston gives details of different methods of opening, and drying, or flushing with fluids the tuberculous peritoneal cavity, with little or no comment, and in conclusion states that

in general it may be said that in an affection of this kind one's first efforts should be directed towards treating the patient, while the second consideration has to do with the most approved method of handling the local process. Whether this is to be done surgically, symptomatically, or specifically will depend, for the present, very largely on the attitude of the physician in charge.

In short, experience is against the free use of the knife in very random operative procedures, still too often undertaken for the relief of a grave and obstinate disease the treatment of which is, nevertheless, most unsatisfactory. We can turn—not with pleasure but at least with satisfaction—to other affections where the contemporary surgeon may justly claim triumphs in improved operative methods. Diseases of the female breast are included in this volume, the chapter being written by Dr. Bloodgood of Baltimore. The coloured drawings of diseases of the breast as seen when the parts are laid open by the scalpel after operation are triumphs of scientific art, brilliant even in a publication issued from the Johns Hopkins University. On the other hand, we question whether the portrait of two dozen pressure forceps (Fig. 530) is likely to be instructive to the beginner who attempts a modern radical operation for removal of a cancerous mammary gland. The instruments cover three-quarters of the field of operation and the divided sternal end of the pectoralis major—one of the points which the illustration professes to show—does not come out clearly. The drawings showing the dissection and removal of the lesser pectoral muscle are much more instructive, whilst further on we find that the process of dissection along the axillary vein is represented by another big crop of forceps. The text in this chapter is very good. The mortality in operable cases in which the complete operation for the removal of the cancerous breast has been performed in the Johns Hopkins Hospital is 2 per cent. Dr. Whitridge Williams contributes the chapter on extruterine pregnancy. He does not advocate operation where there is a quiescent haematocoele, interference being only necessary when suppuration occurs, or when the haemorrhage continues. He considers that when the fetal sac is opened late in pregnancy the placenta should not be removed, except when its partial separation has already given rise to profuse haemorrhage; under such circumstances its removal becomes imperative, no matter how dangerous it may appear. Like all other living authorities, Dr. Williams admits that the removal of the fetus late in extruterine pregnancy is probably still the most dangerous operation which gynaecologists are called upon to perform. He adds that doubtless improved technique will gradually result in diminution of its dangers. Dr. Williams notes that the first vaginal operation for extruterine pregnancy in the States was performed in 1816 by Dr. John King, of Edisto Island, near Charleston, South Carolina. A full-term child was removed after cutting through the posterior vaginal wall.

¹ *An Obstetric Diary of William Hunter (1762-1765)*. Edited with notes by J. Nigel Stark, M.D., F.F.P.S.G., Surgeon, Royal Samaritan Hospital for Women, late President, Glasgow Obstetrical and Gynaecological Society, etc. Reprinted from the *Glasgow Medical Journal*. Glasgow: A. Macdonnell, 1908. (Demy 8vo, pp. 55, 1s.)

² *Gynaecology and Abdominal Surgery*. Edited by Howard A. Kelly, M.D., F.R.C.S. (Hon. Edin.), Professor of Gynaecologic Surgery at the Johns Hopkins University, Gynaecologist to the Johns Hopkins Hospital, Baltimore, and Charles P. Noble, S.D., Clinical Professor of Gynaecology at the Women's Medical College, Philadelphia, Surgeon-in-Chief, Kensington Hospital for Women, Philadelphia. Illustrated by Hermann Becker, Max Brodel, and others. Volume II. Philadelphia and London: W. B. Saunders Company, 1908. (Sup. roy. 8vo, pp. 900, 871 illustrations. 35s.)

It is interesting to recall that another gynaecologist, Gaillard Thomas, was born in Edisto Island, that Marion Sims was a native of Lancaster, S.C., and that Bozemann was born in Georgia, close on the borders of that State, which has been so fertile in cotton and gynaecologists. The chapter on operations of the stomach has for its author a British surgeon, Mr. Moynihan, and no better writer could have been chosen. His views and his methods are well known in this country; in this work he has the advantage of several good illustrations by Max Brödel and Becker demonstrating the different stages of gastrectomy, gastropexy, gastrostomy, and pyloroplasty. Howard Kelly contributes an excellent chapter on the surgery of the ureter, and Noble and Brooke M. Anspach make good use of nearly a hundred pages devoted to the surgery of the kidney. Kelly's article on splenic surgery will be read with interest; and in a chapter on surgery of the pancreas, by Dr. Opie of New York, the illustrations demonstrating operative measures are of the highest quality in every respect, whilst the text has been carefully prepared. A monograph of 130 pages by Dr. John E. Murphy treats of intestinal surgery, including the operative treatment of rectal cancer, fistula, and hemorrhoids, but excluding operations for diseases of the vermiform appendix, a subject taken in hand by Drs. Kelly and Elizabeth Hurdon. The chapter on operations on the gall bladder, bile ducts, and liver by Dr. Ochsner contains some fine illustrations by Becker and others. The chapter on operations for inguinal hernia by Martin of Philadelphia also has an excellent series of illustrations. We must not omit mention of a somewhat original article on the technique of drainage, and of the chapter by Dr. Brown Miller of Washington on complications following operations. In writing on penetrating wounds of the abdomen Dr. Floyd McRae gives some good statistics, and, like previous writers, shows that in modern military surgery nearly all the cases which recovered were those in which no operation was performed. Guy Hünner writes on femoral, umbilical, and rarer forms of hernia, whilst Ross, Norris and Barton Cooke Hirst contribute chapters on Caesarean section, operations during pregnancy, and the operative treatment of sepsis in the child-bearing period.

Nine years ago we reviewed a fasciculus of the useful and instructive reports from the gynaecological clinic in Helsingfors. The present number, like that which was previously submitted, contains an article by Professor ENGSTRÖM himself; its subject is the premature detachment of the normally situated placenta, and is mainly a report and review of one case. Two other contributions make up this instalment of the reports. The first, by Dr. Renvall, is the complete monograph on appendicitis during pregnancy and labour, reviewed in the JOURNAL on January 2nd, p. 24. The second is a brief but interesting note on supernumerary mammae secreting milk, by Dr. Björkqvist. The value of these *Mitteilungen* is high, so that they ought to be found in every British public medical library at least, else much good matter will be lost to us.

We noticed the third edition of *The Principles and Practice of Gynaecology for Students and Practitioners*¹ in our issue of April 1st, 1905, and the fact that it has now reached its fifth is evidence that it is a book that a good many people want. If the title were altered by the insertion of the word "surgical" before "gynaecology," and the striking out of the words "for students and practitioners," we should have nothing but unqualified praise to give it. The writer is a surgeon of experience and resource; his descriptions are detailed and methodical, and illustrated by admirable drawings. Like every intelligent medical man of the present day, Dr. DUDLEY is firm in his faith in the principles laid down by Lord Lister. In his practice he is, if we may be allowed to coin a word, even hyper-Listerian. Special clothing for the surgeon

during an operation—a gauze turban, mask, india-rubber gloves—and the repeated washings of the patient's skin with different chemicals, are here described as essentials. Lord Lister not long ago expressed in our columns his confidence in a simple application of 1 in 20 carbolic acid, and his belief that repeated scrubbing with various chemicals were injurious rather than beneficial. Still it is proper that a textbook should be up to date; and it is better to take too much care about antiseptics than to neglect them. As a textbook of *surgical gynaecology*, we know none better in the English language. But the medical part of the book is as poor as the surgical is good. The author copies the imaginary pathology and the bad local meddlesome treatment of thirty years ago. We will not linger on these unfortunate defects, but only advise the reader to study Dr. Dudley's descriptions of operative details, and go to other works to learn about dysmenorrhoea, endometriitis, sterility, and the minor diseases of women generally.

In one of his entertainments we remember hearing the late Mr. Corney Grain say that there was nothing so mean and cowardly as to say of a man that "he means well," and yet that is exactly what we are obliged to say as to the authors of *Practical Gynaecology*.² They mean well, but they have not attained perfect realization of their intentions. This book sets forth more than a nurse need know, but not enough for a student of medicine. Like some other inexact writers, the authors do not distinguish between sterilization and disinfection. Sterilization of the hands, the patient's skin, the air, and everything in contact with the patient, is impossible. What can be and ought to be attained is to reduce the unavoidable dose of microbes to such a small one that the patient's phagocytes can deal with it. The operation of vaginal hysterectomy is described in a general sort of way; but we should be sorry for the patient on whom any one should attempt the operation with no more information than he finds here. Abdominal section is not described at all; but the after-treatment is. The mode of sterilizing dressings by superheated steam is described; but this is hardly the business either of nurse or student. The writers' favourite antiseptic appears to be a proprietary article the exact composition of which is not known. At p. 163 the nurse or student is told that sometimes the uterus is fixed by adhesions; and that in such cases a course of "plugging and douching" for two or three weeks may lead to absorption of the adhesions. It is not the business of a nurse to express an opinion on treatment of this kind; and for her this piece of information is not required. Looked at from the student's point of view we should have liked to have seen him told that daily plugging the vagina in a case of pelvic peritonitis would cause the patient much discomfort, and that the benefit of it is very doubtful. There is no doubt that peritoneal adhesions are absorbed without either plugging or douching; and most physicians would teach that in pelvic peritonitis the quieter the patient is kept, and the less the parts are meddled with, the better. We hope that Mr. Young's next venture into publication may be work of a more ambitious kind, and that he will think and observe for himself, and not merely reproduce what he has seen done and heard said by other people.

SYPHILIS.

The System of Syphilis,³ now in course of publication, promises to be, when the six volumes are all published, an encyclopaedic work of reference. The subjects dealt with in the first volume may be mentioned seriatim. The history of syphilis has been well done by Dr. Iwan Bloch of Berlin, whose *Ursprung der Syphilis* has been reviewed in these columns (vol. i, 1902, p. 1033). Once more the author insists on the Columbian origin of syphilis, and

Dudley, A.M., M.D., ex-President of the American Gynaecological Society; Fellow of the Royal Society of Medicine, England. Fifth edition. London: Henry Kimpton, 1908. (109s. 8vo, pp. 806; 431 illustrations and 20 full-page plates. 22s.)

³ *Practical Gynaecology: a Manual for Nurses and Students.* By Nettie Stewart, Sister in the Gynaecological Ward of the Royal Infirmary, Edinburgh, and James Young, M.B., F.R.C.S.E., Clinical Tutor in Surgery, and late Resident Gynaecologist, Royal Infirmary, etc. Edinburgh and London: Oliver and Boyd, 1909. (Crown 8vo, pp. 543. Numerous illustrations and plates. 5s.)

⁴ *Oxford Medical Publications. A System of Syphilis.* Edited by Dr. Alex. Power, M.B.Oxon., F.R.C.S., and J. Roach Murphy, M.D., M.C.Camb., F.R.C.S., with an introduction by Sir Jonathan Hutchinson, F.R.S. Vol. i. 1908. London: Henry Frowde, and Hodder and Stoughton. (Roy. 8vo, pp. 416, 63 plates, some of which are coloured. 2s. 2s.)

with so much evidence that it is difficult not to accept the matter as settled, thus coming back to the ideas of earlier writers, such as Astruc, whose views had been to some extent shaken by those who traced the existence of syphilis in Europe back to Roman times, for instance. Dr. Bloch insists on the great harm done to the advance of knowledge of syphilis by John Hunter's unfortunate experiment on himself, and his dogmatic attitude on such points as visceral and brain syphilis. It is dangerous to rely on authority, however great; indeed, the greater the more dangerous. This is exemplified by Ricord's idea that the secondary symptoms of syphilis were not infectious. Dr. Bloch is in error when he gives Ricord the credit of having been the first to draw the distinction between the soft sore and the true syphilitic chancre; the quality of chancres was demonstrated by Bassereau. The microbiology of syphilis has been thoroughly dealt with by Dr. Metchnikoff, and the difficult subject of the general pathology has been well presented and brought up to date by Dr. F. W. Andrews, who is to be congratulated on the fact that he has given illustrations of plasma cells stained by the Pappenheim method, for the plasma cell has been somewhat neglected in this country, apart from British dermatology, of course. Students who come from their pathology lectures and work appear as a rule to know next to nothing about the plasma cell. Colonel Lambkin gives a good review of the primary and early symptoms in the male, whilst Mr. Shillitoe does the same for the female. As to the illustrations of the former article, those delineating the primary sore might have been on a larger scale with advantage—Plate XXXVI, for instance. Dr. G. F. Still contributes an exhaustive review of congenital syphilis. The use of the word "pemphigus" in connexion with the early and rare syphilitic rash of infants is to be deprecated; "bullous syphilide" is much better. As to the treatment of congenital syphilis, the author speaks of $\frac{1}{4}$ gr. and $\frac{1}{2}$ gr. doses of grey powder, but there need be no hesitation in prescribing 1 gr. thrice a day, for syphilitic infants stand mercury well. It should have been insisted a little more that congenital syphilis is infectious, and that every care should be exercised by those in attendance on such infants in order to avoid infection, for it is not so rare a source of spread to the healthy as is supposed. Altogether a good series of articles on some of the special aspects of syphilis.

Dr. MAISONNEUVE's original Paris thesis¹ on the prevention of syphilis by means of calomel ointment has been dealt with already in these columns. An English translation has now appeared, and will certainly prove of interest to those not familiar with French, especially as the translation is on the whole well done. But with regard to the description of the solution of continuity necessary for the penetration of the micro-organism as "the port of entry" (for *porte d'entrée*), it smacks of the ocean and customs returns, and may be due to the fact that the translator is a naval surgeon. Why not "the open door"? The experimental inoculation of syphilitic virus which Dr. Maisonneuve allowed to be carried out on himself—with happy results, fortunately, as far as the prophylactic effects of the calomel ointment were concerned—need not detain us, for it is now a well-known episode in the recent history of syphilis. But a more important point is the ascertained fact that the remedy has been proved to be a failure in several instances (Gaucher, Neisser, etc.). Notwithstanding this, however, the use of the ointment should not be given up, for, applied very early, it may possibly be of prophylactic use. The difficulty of the proof of a negative does not require to be insisted on here.

PRINCIPLES OF SEWAGE TREATMENT.

The Principles of Sewage Treatment,² by Dr. DUNBAR, of Hamburg, is one of the best books on the subject that has yet appeared. To the English reader it is doubly interesting in that it gives an account by an outside authority—for

Dr. Dunbar's experience in dealing with problems of sewage disposal in Germany is well known—of the history and development of modern methods of sewage treatment in this country, and also in that it embodies a great deal of the results of Continental research and practice. The translation from the German has been well done, and the book is profusely illustrated and well arranged.

The first part deals with the historical development of the sewage problem, and we learn that until a few years ago pollution of the streams had received even less attention in Germany than here, but that in recent years the laws which have been passed, and the establishment in Prussia of a central authority for dealing with questions of water supply and pollution of rivers have made the position more satisfactory there. It is admitted that English experience has been the foundation of German practice; but the accounts of what has been done of late years in Germany and elsewhere make it clear that it is quite necessary for the English expert to keep himself fully conversant with foreign ideas.

Two short chapters deal with the present position of sewage treatment and the objects of purification works, and in these the causes of variation in sewages are discussed, and, as might be expected from a Hamburg writer, special attention is drawn to the facts that on the one hand epidemics may be spread by polluted rivers, and on the other that large amounts of sewage may be poured, without causing appreciable nuisance, into rivers of sufficient size.

The bulk of the volume is given to a description of the various methods of sewage treatment and a discussion of their merits. Screening and sedimentation have received much greater attention on the Continent than here, inasmuch as in many cases there the sewage undergoes no further treatment, and the chapters dealing with these matters deserve very careful study.

The discussion of the merits and demerits of septic tanks is worthy of notice, and may be said to represent very closely the view of the majority of English observers. Under the head of methods for the removal of putrescibility, Dr. Dunbar describes surface irrigation on land, land filtration, artificial biological methods, and Degener's method of treatment with powdered lignite, which has been brought into use in several German towns. The "absorption theory" of the action which takes place when sewage is applied to land or artificial beds is very fully set out, and is to a certain extent very convincing. In discussing contact beds the necessity for washing the medium is insisted on. The various methods of distributing sewage upon percolating filters are given in considerable detail, and what is called the Hamburg filter, in which the distribution is effected by spreading the sewage over a top layer of very fine material, is described in full.

The treatise concludes with chapters on the disinfection of sewage, on the supervision and inspection of sewage works, and on the utility and cost of the various methods of sewage treatment. In speaking of the tests to be applied to a sewage effluent, Dr. Dunbar states that one great object to be effected in sewage purification is the removal of the organic sulphur, the presence of which indicates the putrescibility of the liquid, and calls the estimation of its amount the "Hamburg putrescibility test." His standard for a good effluent is that it should be non-putrescible, and should produce no perceptible changes in the stream into which it is discharged.

The utility and cost of the various methods are not compared in any detail, and what is said would be of little service to anyone setting out to formulate a scheme of sewage disposal. It is, indeed, in this direction that some may find the book disappointing. It would have been impossible for the author, within the limits he has set himself, to give sufficient detail to serve for the preparation of a sewage disposal scheme; but he has, however, been very successful in delineating the principles underlying all methods of sewage disposal, and this volume, with its copious illustrations and bibliography, is worthy of the attention of the most advanced student of the subject.

Much good work in the investigation of methods of sewage purification has been done by the Hamburg State Hygienic Institute under Dr. Dunbar, and it would have been useful for the English reader if this work could have been described in detail, but that perhaps would have

¹ *The Experimental Prophylaxis of Syphilis*. By Dr. Paul Maisonneuve. Translated by Fernand L. de Verteuil, M.B. Edin., M.R.C.S., L.R.C.P., Surgeon R.N. 1908. Bristol: John Wright and Co. (Cr. 8vo, pp. 116, 4s.)

² *The Principles of Sewage Treatment*. By Professor Dr. Dunbar, Director of the Hamburg State Hygienic Institute. Translated by Dr. H. T. Calvert. London: C. Griffin and Co., Limited. (Med. octavo, pp. 294, 15s.)

extended the present volume too greatly, and the reader must content himself with the list of references given in the bibliography.

A MEDICAL NOVEL AND SOME MISCELLANIES.
The average representative of the surgeon's craft in modern novels is not a very attractive figure—a cold-blooded abstraction, and often a butcher: but in *The Bias*,⁹ by Miss MARGUERITE CURTIS, he is of quite another character—an idealist who cherishes his illusions, and believes in free will and credits human nature with an inclination towards good. The other professional character in the book—a psychologist—takes precisely the opposite view. Given free choice and a balance of material benefits on the side of evil, no woman, and but seldom a man, would prefer good to evil. Anxious to convince his surgical friend of his error, he persuades him to try an actual experiment by submitting a young ward of the latter alternately to good and evil influences. For six months of the year she is allowed to move freely in the fastest of the smart sets of the metropolis; the remainder she spends in good works in a quiet country village. The result of the experiment we will leave readers to learn for themselves, only promising that the *dénouement* is dramatic, and the interests of the novel well sustained to the end; whether the tests were applied in such fashion as to ensure a decisive result, supposing one to be possible, is not quite certain. In the way of professional criticism no remark need be made, except that it is unusual for a successful Harley Street surgeon to keep, so to speak, surgery hours, remaining at home between six and seven in the evening, on the office-chance of patients arriving. For the rest, the book is quite worth the attention of those to whom problem novels in any wise appeal.

*The Grammar of Life*¹⁰ is the work of one who, "perplexed and troubled" by the intellectual chaos and unrest of the day, set himself to solve the problems involved by reading "books of a varied nature, comprising philosophies, religions, sciences, histories, general literature, and fiction"; he also did a little travelling, and "mingled with both saints and sinners." The result is that he finds "no phenomenon of life, however complex and astonishing, incapable of solution." A second product is this volume, in which, thanks to the capacity of the author for expressing, if not explaining, himself in succinct language, most of the more abstract questions involved by the existence of this world and its inhabitants are dealt with in 237 pages of large print. For the rest, the author's methods are those of other metaphysical philosophers, and his answers will doubtless please those who regard a question as satisfactorily answered when its factors have been restated in other than everyday terms. Who, for instance, could be so unreasonable as to wish for any other explanation of life than that it is a form of motion? or who so unphilosophic as to gird at his existence when he learns that, whereas the universe at large has no why, no wherefore, and no purpose, man, at any rate, has a definite object? This is to go on developing his compatibility with his environment until the optimum is reached. This effected, he will retrograde until apparently he is once more a struggle-for-lifer decked in wodes and skins, unless meanwhile—something else happens. Whether he has a soul is not stated; probably he has not, as his chief characteristics as a living being are the possession of three instincts. Therein he is on a level with the dog, but better off than the cat. The latter is a proud, independent animal, lacking the gregarious instinct which, with those of reproductiveness and self-defence, are the attributes of dogs and men. The gregarious instinct is that which endows its possessor with a conscience and induces him to sacrifice himself for the good of the community. What a conscience is we could not discover. Possibly some other reader may be more fortunate.

To the volume entitled *Reminiscences: Personal, Professional and Philanthropic of John Blackwood, M.D.*,¹¹ attaches

⁹ *The Bias*. By Marguerite Curtis. Edinburgh and London: W. Blackwood and Sons, 1908. (Crown 8vo, pp. 321. 6s.)

¹⁰ *The Grammar of Life*. By G. T. Wrench. London: W. Heinemann, 1908. (Fool 8vo, pp. 250. 6s.)

¹¹ *Reminiscences: Personal, Professional, and Philanthropic of John Blackwood, M.D.* Edinburgh: A. Elliot; and London: Simpkin, Marshall, and Co. (Medium 8vo, pp. 324. Price 6s.)

something of the interest of a conundrum, for though the author writes under an assumed name, it is indicated that there are many who will guess his identity. He was born near Edinburgh in 1832, became M.D. Edinburgh about 1853, taking honours for a thesis entitled *De Dyspepsia*, then obtained honours at the M.B. London examination, practised near that city for some forty odd years, and finally retired to Edinburgh, where he is still living. The avowed object of the book is the solution of the vexed problems of human unfitness and the disclosure of the lines on which health, happiness, and success may first be attained and then preserved; and included in it are a certain number of sketches of personalities famous in Scotland during the first half of last century, and some comparison of Scottish and English systems of medical education and examination. Speaking of the Fifties, during which his studies were completed, the author says that the dissecting and clinical courses in London took a wider range than Edinburgh, and were more thorough; but with regard to lectures and the application of study to practice, the Edinburgh professors excelled their fellows in London. As for examinations, they were less thorough in the Scottish than in the English metropolis. Such instruction as the book contains is conveyed in the form of minute descriptions of conversations held by the writer with various persons, and of equally detailed accounts of his thoughts, feelings, and motives on sundry occasions. The volume, it is stated, is based on a diary carefully kept throughout the writer's life, and this would probably have been guessed by any one familiar with the precision of language and wealth of apparently superfluous detail characteristic of the diaries of early Victorian days. Though some readers may get a little weary, there are many who will find it—in the language of our forefathers—vastly entertaining.

Few folk and no professional riter, as the book itself might say, could rede *The Arcana of Nature*¹² without feeling envious: it is a history of certain people who falsified the saying that there is no royal road to learning. Swedenborg it is true was a well-educated man as times then went, but the knowledge which made him famous was due to no effort of his own, and the others were entirely unlettered individuals when first they gave proof of attainments. For instance, the remarkable exposition of the history and laws of creation from which the present volume derives its title and of which it supplies a reprint, was penned by Hudson Tuttle when a mere youth and scholastically an ignoramus. We say penned, because he, like Andrew Jackson Davis and Swedenborg, received his knowledge in reddly made lots and had nothing to do but rite it down. The kind purveyors were spirits with whose world each of these riters was equally familiar. Nevertheless each differs from the other in his account of its constitution: which is curious. They were alike, too, in the worldly wisdom with which they applied their spook-inspired knowledge, thus attaining financial positions frequently unreachd by mere burners of midnight oil. Finally there was similarity in the circumstances in which their knowledge commonly came. It was usually in the dreamy quiet of their own apartments at the end of a day's work, and Swedenborg for instance received his first communication from the spirits at the end of a generous dinner. As it seemed possible that the same easy rode to achievements without labor lay open to all, we have tried it. The result is this review, for the contents and style of which we consequently neither seek praise nor accept blame. Nor yet for its orthography, which is somewhat on the lines of the book itself, or, in other words, on those of the Simplified Spelling Board. In conclusion, though still dubious as to the true genesis of Mr. Tuttle's work, we congratulate Dr. EMMET DENSMORE on the restraint of his general statements about his heroes and their doings.

Among the annuals which have reached us is the ninth yearly issue of the *Daily Mail Year Book*.¹³ It should doubtless be found useful by those who do not habitually read the daily papers, as it purports to supply information on all the questions of the day. This is effected for the most part by supplying extracts from speeches, Blue Books,

¹² *The Arcana of Nature*. By Emmet Densmore, M.D. London: Swan Sonnenschein and Co. (Demy 8vo, pp. 471. Price, 6s.)

¹³ *The Daily Mail Year Book*. By Percy L. Parker. London: Associated Newspapers, Limited, 1909. (Crown 8vo, pp. 272. 6d.)

or other publications bearing on the special subject, and fairly well summarizing their more recent aspects. In the selection of these the editor, Mr. PERCY L. PARKER, seems as a rule to have exercised a wise discretion, but over the general "make up" the trail of the office boy is unduly obvious. Thus about one-sixth of the whole microscopic space devoted to "Some Medical Matters" is given up to a description of an *ignotum quid* called the Ethological Society; and elsewhere, under the heading "Women's Suffrage Abroad," is hidden a fifty-word account of a really notable event, the genesis of the Research Defence Society. There is a certain quaintness, too, about the section which ostensibly consists of brief biographies of "men and women of our time." On what principle this section was constructed is not clear, as it may be regarded as a hotch-potch of people with whom every schoolboy is well acquainted, and of persons whose existence is of no practical importance to anybody but themselves and their friends. On the whole, one scarcely needed the editor's assurance that these biographies have been "personally revised in nearly every instance"; but this fact lends an attractive flavour to statements such as that Mr. Hilaire Belloc, M.P., is "one of the three cleverest young men in London," the others being Max Beerbohm and G. K. Chesterton. The latter, it will perhaps interest readers of the *Illustrated London News* to learn, is "the most scintillating and epigrammatic of living journalists," as well as a poet, satirist, and controversialist. Information is also supplied as to the more recent doings of some of the personages who figure in these biographies; thus Mr. W. H. Massingham, a "strenuous, brilliant, and sensitive Liberal journalist," "visited Constantinople in 1903." The disclosure of this feat alone makes the book worth buying, for the occurrence of the political marvel of the year "the bloodless revolution" in Turkey seems at once explained. We are glad to see that medical men do not figure largely in this section. Among those whose names appear are Sir James Crichton-Browne, "one of the most famous specialists on mental and nervous disorders and public health," and Dr. C. W. Saleeby, who among other claims to admiration, "married Mrs. Meynell's daughter," and had, it seems, "a brilliant university career." He also "championed the Beard ferment treatment for cancer," and "his father founded the Mount Lebanon Schools."

SLEEPING SICKNESS.

A QUARTERLY report on the progress of segregation camps and medical treatment of sleeping sickness in Uganda,¹⁴ by Captain GRAY, R.A.M.C., issued recently by the Sleeping Sickness Bureau, Burlington House, London, contains some facts of interest and importance. The medical officers in charge of the various camps have been trying the various drugs from time to time put forward as specifics for this disease, and have unfortunately found that all are wanting. As the conclusions are based on the results of the treatment of hundreds of patients under rigid conditions, they are far more valuable than those that can be drawn from experiment with drugs on animals in a laboratory. Dr. Van Someren reports adversely on the combined treatment by atoxyl and mercury, but gives a more favourable account of a new drug, "soamin" (sodium-amino-phenyl-arsinate, Burroughs, Wellcome and Co.). The action of this drug, he concludes, is similar in many respects to that of atoxyl without the toxic effects of the latter, and should, he recommends, replace it for routine use in the camps. Dr. Hodges, who writes an introduction to the report, sums up the question of the treatment of sleeping sickness at the present time as follows: "There is no doubt that the hopes expressed by Professor Koch and others that atoxyl would prove a general and permanent cure for cases of sleeping sickness must now be abandoned. Personally I have never allowed myself to hope for a cure in more than a limited number of favourable cases. This may, I think, still be hoped for, though the time has not yet arrived when we can say with confidence that any apparent cure will remain per-

manent." The report is published by the Sleeping Sickness Bureau, and the formation of this office is clearly going to be of the greatest use in disseminating information quickly and in a form which everyone can easily obtain.

NOTES ON BOOKS.

The Year Book and Diary,¹⁵ which has been issued by the publishers of the *Sanitary Record* for twenty-seven years, is a diary with space for three days on each page, interleaved with thin blotting paper and containing in the first fifty pages a mass of information useful to medical officers of health or sanitary inspectors. The section on sanitary legislation in 1908 is clearly written and may be referred to with confidence. There is a list of thirty-six sanitary and allied societies having their headquarters in London, and detailed particulars are given of most of them, including the regulations as to the examinations of the Royal Sanitary Institute and of the Institute of Sanitary Engineers, but no mention is made of the Sanitary Inspectors' Examination Board. Two other noticeable omissions in the list are the Society of Medical Officers of Health and the National Association for the Prevention of Consumption and other forms of Tuberculosis.

To the ninth volume of the reports of the Ophthalmological Department of the Caroline Medico-Chirurgical Institute in Stockholm,¹⁶ the editor, Professor WIDMARK, contributes three articles. He describes a case of bilateral detachment of the retina due to inflammatory extension from an old empyema antri in which complete recovery took place; three cases of toxic amblyopia of unusual origin, two being due to excessive coffee drinking, and one probably to arsenic; and five new cases of sympathetic ophthalmia treated by sodium salicylate, with three successes. Dr. Lindahl details the results of his investigations into the bactericidal properties of the lacrimal secretion. Dr. Forsmark describes a remarkable case of bilateral symmetrical epibulbar tumour, which he considers a "leucosarcoma"; the histological picture is, however, uncertain, and the possibility of gumma is excluded only by the long duration of the swelling. Dr. Lamm figures an unusual appearance of the fundus due to a congenital anomaly, possibly a "rest" of the hyaloid artery, and also recounts a case of orbital tumour. The first article is from the pen of Dr. Haas Gertz, and gives the theoretical basis and method of use of a new apparatus for estimating refraction in inverted ophthalmoscopic images.

Miss McISAAC's *Hygiene for Nurses*¹⁷ is, on the whole, a useful compilation. It takes the reader satisfactorily through the usual course of elementary hygiene, without ever verging on originality. The information given about foods and adulteration is practical but somewhat scrappy. The section on medical inspection of schools consists almost entirely of quotations from the regulations drawn up for medical inspectors in the United States, and is out of place in a work addressed to nurses.

A "little learning" is, perhaps, more dangerous in nurses than in most other members of the community, and it is just this mitigation of wholesome ignorance which is likely to be developed by Dr. G. H. HOSKIE'S *Practice of Medicine for Nurses*.¹⁸ Nurses ought not to "practise medicine." So much the author admits in his preface, where he writes: "Because it is the author's belief that the nurse should neither diagnose nor prescribe, little space has been given to differential diagnosis and the dosage of remedies." Nevertheless, the whole book is a temptation to the ambitious nurse who might be desirous of doing those things. After a dissertation on the treatment of various forms of tonsillitis, including even the incision of abscess, the various complications of this disease are enumerated, and the author adds: "Because of the seriousness of all these affections it is usually advisable to have a physician direct the treatment of every severe case of tonsillitis." In this country we would substitute the word "always" for usually. As a manual of nursing the book is inferior to any of the well-known textbooks.

MEDICAL AND SURGICAL APPLIANCES.

Compress, Haden's Patent Compress Heater.

DR. WILLIAM E. BURTON (London) writes: I desire to call attention to a very simple and excellent device for the heating of compresses, fomentations, dressings, etc. The apparatus consists, as shown in the cut, of two parts, of which the lower is to contain hot water, and to be placed on a gas or spirit stove; and the upper part is a tray, pierced centrally, to permit the vapour from the boiling water to heat the compresses, etc., placed thereon. Both

upper and lower parts are made of copper, tinned inside, and each is furnished with a wooden handle which allows of their being moved without risk of burning the hands. I have had occasion to make use of this very handy little apparatus, of which I cannot speak too highly as regards (a) efficiency, (b) simplicity, (c) cheapness. It does away completely with the delay and risk of scalding (arising from the usual fomentation methods, in the absence of a properly trained nurse) and saves the doctor's time in explaining. I have no financial interest in this invention, which is known as "Haden's Patent."

THE STANDARDIZATION OF DISINFECTANTS.

The questions of introducing a method of standardizing disinfectants, and the influence of organic matter upon germicidal value, have been investigated by C. J. Martin and H. Chick.¹ As the results of previous investigations on the process of disinfectants,² the latter came to the following conclusions:

1. A complete analogy exists between a chemical reaction and the process of disinfection, one reagent being represented by the disinfectant and the second by the protoplasm of the bacterium.
2. In the case of anthrax spores, the disinfection process proceeds in obedience to the equation for a unimolecular reaction, if numbers expressing "concentration of reacting substance" are replaced by "numbers of surviving bacteria."
3. The simple law does not hold good in all cases—for example, paratyphoid bacilli—for there are variations in individual bacilli.
4. Temperature influences the process regularly, and Arrhenius's equation can be applied. In killing paratyphoid bacilli with mercuric chloride, the reaction velocity increases about three times when the temperature is raised 10° C., while when phenol is employed, the velocity is increased from seven to eight times.
5. It is deduced from the fourth conclusion that considerable advantage is gained by the use of warm solutions of disinfectants.
6. It could be shown that a definite logarithmic relation exists between the concentration of the disinfectant and the mean reaction velocity of disinfection in the case of mercuric chloride. It is not, however, the concentration of the salt but that of the metallic ions which stands in relation to the reaction velocity.
7. Some evidence was obtained that, in disinfection with mercuric chloride, a toxic compound is formed between the metal and the substance of the bacterial cell. This compound prevents all further growth, but vitality can be restored by the addition of a large excess of soluble sulphide.

In the more recent article it is pointed out that disinfection is most often required for utensils, soiled linen, closet pans, dejecta, etc., and for the washing of walls and articles of furniture, while less frequent objects of disinfection are the sterilization of surgical instruments, and

hands, and the preservation of serum, vaccine, and the like against bacterial contamination. With regard to standardization, Martin and Chick hold that it must be carried out at a constant temperature, as the disinfection process has a high temperature coefficient. They arbitrarily selected a temperature of 20° C. In order not to complicate the test, it is, they state, desirable to employ a constant number of bacteria per unit volume and to conduct the experiment in such a way that the bacteria shall possess a constant degree of resistance. Since it has been shown that a logarithmic relation exists between the reaction velocity and the concentration of the disinfectant, it follows that the time factor must also be kept constant, and thirty minutes is suggested as a suitable time during which the disinfectant may be allowed to act on the bacteria. In the case of metallic salts, a sulphide must be employed to neutralize the traces of disinfectant carried over with the test sample, and in the case of mercuric chloride, a large excess of this substance in solution is required to decompose the compound formed between the metal and the substance of the bacterium.

They find that a disinfectant varies in efficiency toward vegetative organisms, and in some cases the efficiency is ten times as great as it is in the case of other bacteria. In the case of spores, the action of phenol and emulsified disinfectants is too feeble for practical use, and the metallic salts are by far the most efficient germicides. They found that the ratio between the concentration of phenol required to kill the same number per unit volume of sporing and vegetative forms in the same time varied between 17 to 1 and 25 to 1. A virulent strain is somewhat more difficult to kill than a non-virulent strain of the same microbe. Owing to the variations in the resistance of different germs toward the same disinfectant, it is necessary to use one arbitrarily selected germ for testing purposes. *B. typhosus* appears to be suitable, since it occupies a position which in many respects might be termed average, but it is not necessary to employ a virulent strain. The presence of 10 per cent. of blood serum in the testing material reduces the efficiency of 1 per cent. phenol by about one-eighth. The effect upon emulsified disinfectants is greater. The effect on mercuric chloride is much greater, a 0.5 per cent. solution being reduced to from 0.6 to 0.06 of its original value as the concentration of the serum was increased from 5 to 30 per cent.

The presence of particulate organic matter—for example, animal charcoal, dust, albumen precipitated in a state of fine division, bacteria, and faeces—was found to affect the germicidal value of emulsified tar acid disinfectants to a much greater extent than that of phenol solution. The whole of the emulsified tar acid could be removed by a suitable addition of the particulate organic matters named. The authors have drawn a curve representing the adsorption of tar acids by animal charcoal. When a 3 per cent. suspension of dried and finely particulate faeces is employed, the efficiency of phenol is only reduced by about 10 per cent., while that of the emulsified tar acids is reduced from one-third to one-eleventh of the original value. The soluble commercial cresols occupy an intermediate position, the reduction depending on the solubility. The reduction in the case of the emulsified tar acids was found to be higher the finer the emulsion. Within the limits of concentration of disinfectant employed the amount of emulsion removed by the particulate faeces was approximately proportional to the concentration of disinfectant. The removal was found to be due principally to adsorption of the emulsion upon the surface of the particles. The authors give the details of a method of standardizing disinfectants in the presence of faeces, based on the foregoing considerations.

In a further communication³ the same authors briefly deal with the power of an emulsified disinfectant to kill germs, as compared with that of the same disinfectant after solution of the active principles. They found that the emulsified condition was important, inasmuch as the germicidal value sank considerably when the emulsion was destroyed by dissolving the tar acids in alcohol. They were able to demonstrate that the emulsified condition permitted of adsorption of the emulsion particles by bacteria, and in support of this they adduce evidence of the disappearance of emulsified particles. A curve is plotted which shows the rate of adsorption.

ROYAL COMMISSION ON VIVISECTION.

FOURTH REPORT.

(Continued from page 229.)

We continue our abstracts from the evidence of which the minutes are contained in the fourth report of the Royal Commission on Vivisection, issued in December, 1907.*

Evidence of Dr. A. D. Waller, F.R.S.

Dr. Waller gave evidence as to some of the statements made in Miss Lindaf-Hageby's book, *The Shambles of Science* (original edition). With regard to the "dog injected with a substance derived from a lunatic," he was present at the lecture, and could identify the dog. As regards "a troublesome dog," on going through the description he could only say he saw nothing of the sort. He did not think this lecture took place in the university. It could not have taken place at the date given by Miss Hageby, because the laboratory books showed the lecture on "a dog injected with a substance derived from a lunatic" took place on that date (February 26th). He agreed that it might have taken place somewhere else. He was present at the lecture on March 12th, described as "The only completely satisfactory method." Asked if he considered that Miss Hageby's book gave a fair and accurate representation of what took place, he said, Oh, no; it was a representation coloured by the sentiments of the lady—in good faith, no doubt. Dr. Waller was then asked about the lecture on December 3rd, 1902, as to which she stated on p. 11:

He inserted one point of a pair of forceps under the skin behind the skull for a moment. . . . The animal begins to struggle, quickly moves its limbs to its back, and tries with hands and feet to thrust away the instrument.

The witness's note on this was:

The ordinary reflex movements that do not imply any sensation.

On page 12 she said:

The wound is cauterized.

His note was:

Presumably the cord is destroyed.

That meant pithing. He meant that there was no cauterizing. Then on page 13 was the episode of the frozen rabbit left in an ice-box, and on the next page the description of its start with horror. What happened was that the rabbit was put in an ice-chest—a refrigerator—to lower its temperature, but the refrigerator was not cool enough, and the animal's temperature was not lowered. It was not anaesthetized. It was simply put into the refrigerator to show that its temperature did not go down as that of a cold-blooded animal would. There was no vivisection at all, and no freezing of the animal. Miss Hageby's description was:

The animal was taken out of the freezing machine quite unconscious but frozen stiff, like a piece of wood. With all signs of terror the animal springs back, trying to get away, but half-paralysed by the cold and half-fascinated.

The witness's comment upon that was simply that all that was impossible. Asked about February 3rd, 1903, when there was said to have been

an experimental production of blood clotting by injection of a nucleoprotein,

Dr. Waller said he was there and gave the anaesthetic; and there was a description on page 30 of the anaesthetist looking "most careful, as if he were attending the precious life of some human patient," and so forth. It simply meant that it was one of the very first lectures delivered in the laboratory, and he laid great stress upon anaesthesia, and gave the anaesthetic himself in order to show how it was to be done by other people in the laboratory. Asked, as regards all these experiments at which he was present, if there was any case in which the animal was operated upon either without anaesthetics or without sufficient anaesthetics, he replied, Certainly not. No experiment had been performed in that laboratory in

which an animal had not been completely insensitive to pain. If there were movements in the animal, they were reflex—the ordinary convulsive movements that happened. Asked about the lecture on February 19th, described as

An experiment that is not supposed to be useful, he said he was present. On page 59 they said:

The lungs are exposed, and artificial respiration kept up by means of a pump attached to the operation table, and worked by electricity.

His addition to that was "pumping air plus chloroform vapour"; that was to say, the artificial respiration apparatus was attached to an apparatus for producing anaesthesia. That was the usual method. On page 60 it was said:

We can be almost certain that the dog has been also curarized, because it is absolutely still, with the stillness that is characteristic of the "Hellish Woolah."

His comment on that was that it was not curarized. In his notes it was stated that:

The animal was absolutely motionless under artificial respiration through a chloroform flask giving between 2 and 3 per cent. of chloroform vapour to the insufflated air. I was present.

He had been measuring the percentages at about that period. Asked if that would be sufficient to account for the animal's being completely still, he said, Absolutely; and it would run the risk of being overdosed with that percentage. Asked as to the lecture on February 26th, he said it was on the circulation, on the effect of choline, which was the particular thing—one of the alkaloids, one of the pyramines. "A dog injected with a substance derived from a lunatic" was a description, after a fashion, of choline; it was a substance derived from a lunatic. The animal was fully anaesthetized. He was absolutely certain there was no interval in which the dog was suffering. As to March 12th, when the lecture was described as "The only completely satisfactory method," and Miss Hageby began by stating, "He has doubtless found the remedy to be curare," the witness said he was absolutely sure no curare was used. His note was:

Incorrect. The animal was under artificial respiration through the chloroform flask, getting between 2 and 3 per cent.

There was a remark on p. 134 to the effect that at the end of the lecture one other—the director of the laboratories—came to try the action of betain. He remembered that, because it was a preliminary trial of betain, and if any point had been made of that he would explain it. On p. 135 there was the following statement:

When an anaesthetic or narcotic has been given to the animal the students are told so, or they see the anaesthesia being kept up by repeated doses of the anaesthetizing agent.

His note was "Not necessarily." On this occasion the anaesthetic was certainly given. Asked what he meant by "not necessarily," he said one did not mention it on every occasion. At every turn the animal was anaesthetized, but it might often happen that one did not mention it. He took it for granted. He did not think he would necessarily say so himself. In reply to further questions, he said his definition of light anaesthesia and deep anaesthesia implied that there was no sensitiveness to pain in light anaesthesia any more than in deep anaesthesia. He had given the following definition:

The fingerpost between this first stage and the next is quite clear; if when the conjunctiva is touched the eye winks, the anaesthesia is "light," if the eye does not wink the anaesthesia is "deep."

In deep anaesthesia all sensation and voluntary motion were lost. In deep anaesthesia the movements were more profoundly affected. Asked by Sir William Church as to a statement by a witness, who said that the fall in blood pressure which took place on the administration of chloroform was produced really by asphyxia and by that alone, and not by the chloroform itself, Dr. Waller said that chloroform of itself tended to produce a fall, but that asphyxia tended to produce a rise. Respiration and the heart were interfered with; the respiration activity diminished and the heart activity diminished, and the vasomotor centre relaxed, and there was a fall of the pressure and diminution *all pari passu*. He had no hesitation in saying that the action of chloroform did at times diminish the blood pressure. In reply to further questions, Dr. Waller quoted the following passage

* London: Printed for His Majesty's Stationery Office, by Wyman and Sons, Limited, 103, Peter Lane, E.C. And to be purchased, either directly or through any bookseller, from Wyman and Sons, 103, Peter Lane, E.C.; or 32, Abingdon Street, Westminster, S.W.; or Oliver and Boyd, Edinburgh; or E. Ponsonby, 116, Grafton Street, Dublin. (1908.)

from a lecture in which he dealt with *The Shambles of Science*:

If the two young ladies under whose name the publication entitled *Shambles of Science* has appeared, came simply to get "copy," the case is easily understood; but I am unwilling to believe this; and, indeed, the case looks to me much more like that of a pair of very ill-advised busybodies supporting each other through a trying ordeal for the sake of what they imagined to be an errand of mercy. I am sorry they came. I should have told them or any other non-professional women that they had better not come to such lectures, for they would run the risk of being misled, and, as evidenced by experiments where no suffering to living animals was caused. Indeed, one would look very much askance at the young woman who should be able to look on while an animal was, as she imagined, undergoing torture. For the naked details of even a properly conducted vivisection, ignorantly considered, as must be the case if they are considered at all by an unprofessional person, appear revolting—so do the details of a surgical operation or of the slaughter of an animal for food, or of the proceedings in the dissecting room, and the post-mortem room. The minute and graphic account of such details by ignorant women is from every point of view mischievous and deplorable, and I very much regret that these two unfortunate ladies should have obtained the opportunity to torment themselves and their readers by their conscientious misrepresentations. Physiologists, when vivisection is necessary, do not take either pleasure or pain in its naked details, and they systematically take due precautions to fully anaesthetize animals required for experiment. The incredible motives sometimes attributed to physiologists by well-meaning people, and the unlimited adjectives and substantives by which they are held up to public reprobation can only be left to the antidote of their own excess. It is really labour lost to be constantly pleading "Not guilty" to this, that, or the other quite outrageous statement; we can only wonder that well-meaning people can so quietly harbour such infamous thoughts. Nor have we failed to question our own conscience. We well know that physiologists are subject to the common laws governing the human mind, and that habit must tend to engender inattention, and that inattention would be cruelly. We are on our guard against our own inattention, but knowing that we are human, we do not resent indignantly as might be expected of us the reminder to be on our guard that is contained in the denunciations of our critics. We also know that there is evil in the appearance of evil, that things right and proper in themselves, but offensive of appearance, ought not to be exposed. And if exposure by even competent authority must offend and injure the imaginations of ordinary men and women, how much more injury and offence to the public mind will be committed by incompetent and self-deluded women who have entered what is, to their minds, nothing more than a chamber of horrors, where in reality the "quivering flesh" and "palpitating heart" and "tortured nerves" are more often than not only the living parts of dead animals, and where, in any case, an animal, even if alive, has been absolutely deprived of sensation. When one attempts to realize what kind of images must hold possession of an ignorant, prejudiced, and sensitive person—man or woman—who has seen, without understanding, he ceases to wonder at bad language, yet what can be hoped to say that shall reach the mind of the deluded fanatics whose pity has been fanned to hatred by agitators. And can it be expected of us that we should say anything at all to persons who can employ sensational literature to poison the wells of human sympathy? In this laboratory—and no doubt in others—our very first concern is to administer anaesthetics properly when anaesthetics are required. And I make the deliberate statement that animals in this laboratory are anaesthetized with as great certainty and accuracy as are the patients in any hospital in the United Kingdom. Can it be necessary to tell you that we do not juggle with bottles of "colourless and odourless" liquid, as imagined and stated by the two ladies who have visited these "shambles"? You shall see for yourselves what takes place outside the lecture room whenever it is necessary to anaesthetize an animal. I have chosen cats for my demonstration, since the demeanour of these animals is most familiar to us.

Asked as to a statement by a witness that when artificial respiration had to be kept up, and for that purpose tracheotomy was performed on the animal, the tracheotomy was performed before any anaesthetic was administered. Dr. Waller said, "Not in my practice, most certainly." He knew of no laboratory in England in which tracheotomy would be performed on an animal before the administration of some anaesthetic. He would disapprove of such a practice. In reply to further questions, he said an animal immobilized by curare could be anaesthetized. He had never known curare administered without anaesthetics. If 2 per cent. of chloroform was present, an animal was of necessity under the influence of the anaesthetic. If artificial respiration was going on with that percentage of chloroform vapour he knew he was on the safe side as regards pain to the animal, and on the unsafe side as regards its life. He was more liable to lose the animal than to let it out of anaesthesia. Asked about Miss Hageby's description of the killing of the dog by blowing air into the jugular vein, he said he did not remember the

details. They did not sound to him very likely, but what he should imagine might be the explanation of what she saw, or thought she saw, would be that with air in the veins convulsions happened, and in order to make sure, as any person would do, the lecturer said "Kill the animal," meaning simply to put the scalpel into the medulla. That would be one's natural action if one saw a convulsion on the part of an animal that had been so treated. It was common to have struggling when the air was in the vascular system. It was of the same nature as the struggles of apoplexy or anaemia. There was absolutely no sensibility to pain. Asked by Dr. Gaskell how he could tell when a sufficient amount of an anaesthetic had been given to prevent the animal from feeling pain, Dr. Waller said one's ordinary quick and practical test was the conjunctival reflex. The differences between the reflex and automatic movements and the convulsions were often very deceptive as indicative of conscious voluntary impulses; but still one would tell by the behaviour of the animal whether the movements were indicative of sensation or not, simply from their general character. Proceeding, he said that in the state of light anaesthesia one knew that the first movements to disappear in the case of a man were the obviously purposive movements, and one knew that when that happened there was no sensation; and one judged from the character of the movements that the animal was in an analogous state, having no sensation. But, as a matter of fact, his practice, and he thought, the practice of most physiologists, was to go as far as the conjunctival reflex. Asked if, when complete abolition of the conjunctival reflex had once been obtained, a very considerable time elapsed in which no chloroform was given before any sensation of pain ever came back, he said, Yes. He agreed that there was a very considerable time after the conjunctival reflex had been abolished in which one might be perfectly certain that there was no sensation of pain; and he would go further: One knew that one could keep the animal anaesthetized; that if one had brought it down by 2 per cent., one could keep it there at $1\frac{1}{2}$ per cent., 1 per cent., and a $\frac{1}{2}$ per cent. as time went on. He had had an animal as long as twelve hours under anaesthetics, and at that time only a very low percentage indeed was wanted to keep it under. In reply to Mr. Tomkinson, he said he would not call morphine an anaesthetic, but a narcotic. It was a question of words again. He could imagine the stupor produced by morphine or alcohol being so profound as to amount to anaesthesia. He had kept cats under for a very long time; dogs he had kept in perfect anaesthesia for three or four hours. He had found no difficulty in anaesthetizing dogs. He had not lost a dog for several years. Asked about Mrs. Cook's statement to the Commission that she had witnessed baking and freezing of animals at the Imperial Institute, he said that no heating experiments were ever made in the laboratory. The only ones ever made were on reducing the temperature. The baking was pure imagination absolutely, and the freezing was never there. He noticed the temperature of the ice-chest at the time was noted as 8° Centigrade, and no animal was exposed to a temperature below the freezing of Fahrenheit.

(To be continued.)

ALDERMAN F. R. Mutch, M.D., was the recipient on January 20th of an illuminated address from the Nottingham Medico-Chirurgical Society. Dr. Mutch, who has been in practice in Nottingham for some thirty years, has held a seat on the City Council for two-thirds of that time, and has been Chairman of the Health Committee for the past nine years. In view of his services to the city and the credit which they reflected upon the medical profession, the Nottingham Medico-Chirurgical Society determined some time ago to recognize them formally in the fashion stated.

In the large seaport town of Karachi, the health officer, Dr. Kaka, D.P.H., induced the municipal scavengers to be inoculated with Hafkine's plague prophylactic. The greater number, that is, 1,114 out of a total of 1,206, were inoculated before the beginning of last plague season. At the close of the season it was found that the mortality from plague amongst the uninoculated was 11, and amongst the inoculated 3. To put the result in another way, if the 1,114 inoculated persons had suffered to the same extent as the 92 uninoculated, they should have had 133 deaths instead of 3, a difference of 96 per cent.

IRISH AND SCOTTISH DEGREES AND DIPLOMAS.

SIR CHARLES E. BALL took the chair at a well-attended meeting of the members of the Irish Medical Schools' and Graduates' Association and of the Scottish Medical Diplomates' Association held at the Hotel Cecil, Strand, on January 21st, to consider the exclusion of graduates of the universities and the diplomates of the Scottish and Irish Corporations from candidature for positions on the staffs of certain hospitals in England.

Dr. H. MACNAUGHTON JONES moved the following:

That the present exclusion of all persons who do not hold certain qualifications from candidature for honorary positions on the staff of a public hospital is contrary to the public weal, and is a restriction which is not to the interest of the institution itself, excluding, as it does, all other candidates who may have exceptional claims to fill such positions.

The principle advocated had been accepted and approved in the three divisions of the United Kingdom on three occasions—at the annual meetings of the British Medical Association in Dublin (1887), Glasgow (1881), and Bournemouth (1890). It had received the approval of a Special Committee of the British Medical Association appointed to consider the question, and of the Select Committee of the House of Lords that had under its consideration the organization of the metropolitan hospitals. The BRITISH MEDICAL JOURNAL of February 4th, 1893, said that the efforts made to remove the invidious distinction which had come into existence in England had the warm support of the British Medical Association, which at three general meetings had condemned the monopoly by a large majority. It must at the outset be understood that Irish and Scottish graduates or diplomates did not complain that they were not appointed to English hospitals: it was that they were excluded from candidature though they held the higher degrees and qualifications of their universities and colleges. There was a rule which declared practically that they were not to enter within the sacred circle of favoured candidates for certain hospitals. At present no Scotsman or Irishman, no matter how well qualified by experience or original research he might be, who did not happen to hold the favoured English qualifications, could apply for an appointment in these hospitals, and the slur was publicly thrown in their faces by advertisement in the lay press. The two reasons given by those who defended the practice were first that these institutions were not State institutions; they were not on a par with the public services, military or civil; they had been endowed by private munificence and were supported by private donations and subscriptions, and those entrusted with the control of their maintenance and administration were entitled to make any rules or regulations they saw fit for their efficient conduct and welfare; secondly, that the rules requiring certain qualifications to be held by candidates were justified by the inferior standard of knowledge required from, and the lower ethical restrictions placed on, the possessors of all other qualifications. In regard to the first, it must be remembered that it never could have been the intention of the founders of those hospitals to limit their sphere of usefulness to the State, whether as a means of treating the sick poor or as affording opportunities for the study of disease and the discovery of new means of cure. When many of them were founded the conditions of medical education were widely different to what they were now, and the centres from which instruction and knowledge were to be obtained comparatively few, and situated widely apart, in England, London alone, in Scotland, chiefly Edinburgh, in Ireland, Dublin alone. It was natural that the authorities of the hospitals, animated as they were still by the views of their medical staffs, should impose restrictive regulations in regard to the qualifications of those seeking office; to secure such qualifications, residence was compulsory in one of the great centres of medical education. Those corporations had thus a monopoly in the supply of candidates—also the hospitals were closely associated with the teaching staffs of the schools. The interests of the corporation, the school, and the hospital alike demanded a close unity of all three. The reputation of each in attractiveness of its diploma, teaching, and the ability of the staff touched the financial prosperity of all three. Gradually, however, new centres of learning

came into existence; facility through new means of intercommunication and transport enabled students to take that diploma which was most to their future interests and in accord with their circumstances at the time to obtain. Hospitals with teaching opportunities multiplied enormously. The State insisted on having its share in regulating the standard and character of the education required of those whom it took under its protection by registrable recognition. The State by Acts of Parliament interfered with the charters of the colleges by alteration and amendment, and, in the instance of the Royal College of Surgeons of Ireland, deprived it of the privilege of securing that appointments to certain hospitals in Ireland should be only held by those who possessed its diploma. Gradually, through the Medical Acts, they found the State taking a greater part in the scheme for the education of medical men, and also through its representatives on the General Medical Council making itself in a degree responsible for the efficiency of the institutions, whether schools or hospitals, on which that education depended, for every hospital recognized by the General Medical Council became part of the local school. They thus found that the condition of affairs to-day, when a triple qualification was demanded of registered practitioners, and when there were two grades of graduates and diplomates, was widely different from that which existed when the diplomates of the different corporations appropriated certain hospital appointments and the authorities of the hospitals acquiesced. It seemed, on the face of it, paradoxical that the higher degrees in medicine of any university should not confer the same privilege as an ordinary Membership Diploma of a College of Physicians, and that the higher degree in surgery to be obtained only by conforming to exceptionally severe conditions were to be ignored by a hospital authority, and to be looked upon as insufficient to entitle their possessors to hold hospital appointments. The State had the right to-morrow to enact that the hospital appointments in dispute should be open to men who possessed such qualifications as it considered adequate. And if the hospital authorities persisted in upholding that prohibition rule, then the demand for a State licence which would entitle its holder to become a candidate for any public appointment in the State would take a practical shape, and the diplomas of the corporations would become ornamental appendages which could be ignored or obtained at option. As to the second reason given for the rule—namely, that the character of the Scottish and Irish examinations was not on a par with the English ones, he should feel inclined to meet that with a simple denial, and say that the *onus probandi* rested on those who made the assertion.

Dr. A. J. HORNE (President of the Royal College of Physicians, Ireland), in seconding the resolution, said that he considered the examinations in Ireland and Edinburgh would favourably compare with any examination held in London. If they succeeded in enlisting in their services the medical and the lay press he thought that the particular object which they had met together to secure would soon be an accomplished fact.

Mr. AUGUSTUS P. HILLS said if the Governors of hospitals would take the trouble to find out that the different degrees had not the differences that they were supposed to have, a great deal might be done.

The CHAIRMAN said that the Scottish and Irish graduates were able to hold their own not only in entrance examinations but in their devotion to duty, which ensured their selection for the highest ranks of the profession. There was a sort of national spirit which tended to make them prefer a Scottish graduate for a Scottish appointment, and an Irish graduate for an Irish appointment, and an English graduate for an English appointment. Nobody quarrelled with that. But what they had a right to protest against was the statement that "you are not fit to become candidates." If that point were put plainly and temperately before the public, he thought it would end in what the associations so much desired to be carried out.

The resolution was unanimously adopted.

Dr. WALSH moved:

That the advertisements in the columns of the lay press that honorary offices in certain hospitals are open only to those holding the diplomas of some particular corporation gives to the public the impression that such restrictive regulation is justified by the exceptional character of such qualification, which is not in accordance with fact.

Mr. JOHN LENTAIGNE (President of the Royal College of Surgeons, Ireland) seconded the resolution. He held it was absolutely untrue that the restriction was justified by the exceptional character of the qualifications stated. He said without hesitation that the examination for the Fellowship of the Royal College of Surgeons in Ireland was as high and difficult an examination as that for the Fellowship of the Royal College of Surgeons of England. The public advertisements in the *Times* and other newspapers could not be interpreted in any other sense than as implying the inferiority of the bodies that were excluded. They cast a glamour on those other bodies—a glamour which was absolutely unjustified and undeserved. In Ireland this was called a boycott of Irishmen and Scotsmen in favour of certain corporations in London. These corporations ought not to require the support of such methods; they should have been only too glad to repudiate and refuse the advantages which accrued to them in that way. It was asked that the objectionable advertisements should cease. They had a right to stir up public opinion, to stir up Parliament if necessary, and he believed that Parliament would step in to stop the present state of things. If the hospitals did not set their own houses in order it would be done for them, and perhaps here might be more things done for them than they would like when the time for reform came.

Dr. MACAN said that the stigma of the objectionable advertisements did not simply affect men who might or might not be candidates for hospital appointments, but, when conveyed in the advertisements of the lay press, it affected every practitioner in England who might derive his qualification from one of the Irish or Scottish bodies.

The resolution was carried unanimously.

Sir THOMAS GALLWEY, K.C.M.G., moved:

That these resolutions be forwarded to such persons as the councils of the two associations may determine.

He thought that the opposition came from the lay persons on the corporations of the hospitals.

Dr. L. S. McMANUS (Direct Representative for England on the General Medical Council), in seconding the resolution, said that he was there as an Irish graduate of an extinguished university. The university might be extinguished but the individual members of it were very much alive, with plenty of reserve vitality and plenty of fighting power when occasion arose, when any injustice was inflicted upon them by their colleagues in England. It was not, he thought, quite accurate to say that the opposition came from the laymen on the boards of hospitals. He thought the usual procedure was this: The board of governors asked the medical board to send them up a certain number of names and the medical board carefully excluded Irish and Scottish colleagues. That was only confined to some of the larger hospitals and only confined to one or two corporations. As to the Poor Law of England the Irish had a very good look in, for any number of Irishmen occupied Poor-law offices throughout England. He was a member of the Battersea Council, and when the post of medical officer became vacant two years ago, forty medical men had a meeting and selected an Irishman, a Nationalist Catholic, to the exclusion of a great many Englishmen. So that the spirit of bigotry was not universal. But, as a rule, those bodies were not representative; they were run by a little clique who had resolved themselves into a sort of self-admiration society who were absolute monopolists and intended to keep the monopoly as long as they could. But he believed that retribution was coming, and when the one-party system had become a fact the corporations would have a very considerable difficulty in maintaining their present position. Their associations had suffered in the past from a certain amount of idiotic pride. It had not been considered dignified to take the lay press into their confidence. An attack could be made through the lay press, and yet their associations never seemed to hit back through the lay press; they were too proud, and the people throughout the country were listening to all sorts of faddists, believing that the members of the associations were far worse than they were. He hoped they would take the lay press into their confidence, and that through its columns their grievances might be ventilated by some who could efficiently and wisely put them before the public mind. He felt certain that if they only appealed to the justice of Englishmen their grievances would very soon be remedied.

After Dr. FITZGERALD POWELL, Dr. W. DOUGLAS, and Dr. NORBURY had spoken, the resolution was unanimously adopted, and the meeting closed with a hearty vote of thanks to the Chairman.

In the evening the members dined together at the Hotel Cecil under the chairmanship of Sir CHARLES M. CUFFE. Dr. H. MACNAGHTON JONES, in proposing the toast of "The Scottish and Irish Universities and Corporations," said that as far as the United Kingdom was concerned the birthplace of anatomy was Edinburgh. Sir CHARLES B. BALL acknowledged the toast, as also did Mr. J. LENTAIGNE, who asked for sympathy for the unfair treatment of the Royal College of Surgeons of Ireland. The toast of "The Irish Medical Schools' and Graduates' and Scottish Medical Diplomates' Associations" was submitted by Dr. A. J. HORNE, and was replied to by Dr. MACAN and Dr. D. WALSH. The health of "The Chairman" was given by Colonel JAMES MOORHEAD, and the proceedings terminated after the CHAIRMAN had responded.

THE WORKMEN'S COMPENSATION ACT FROM A MEDICO-LEGAL POINT OF VIEW.

A DISCUSSION of considerable interest to doctors and lawyers who are concerned with the working of the Compensation Act was opened last week at the Medico-Legal Society, when a paper was read by Mr. Arthur S. Morley, F.R.C.S., entitled, *Some Experiences of the Difficulties and Abuses of the Workmen's Compensation Act*.

He explained that, while the Act was designed to provide relief for the genuine worker, it had imposed much hardship on employers by exposing them to the plots of lazy and dishonest workmen, aided by the less reputable members of the legal profession. He knew as a fact that it was the custom of some of the latter gentry to ascertain day by day from the receiving-room porters at hospitals the names and addresses of casualties, and to offer to take charge of the cases of injured men. Having placed every difficulty in the way of an amicable settlement to increase his own costs, a solicitor of this class would allow the case to be fought, with the result that the claimant only recovered a portion of the compensation, the remainder going to the solicitor. As a result, employers and insurance companies were inclined to settle rather than fight, for although the defence was often good, nothing could be extracted from the other side in respect of costs. The reader of the paper also drew attention to the extraordinary amount of malingering occasioned by the Act. Injuries to hands and fingers were often turned to profit. A man would pretend he could not get a proper grip as a result of a slight injury; and if his employers had no work of a light character to offer he was entitled to compensation. It was impossible for the examining surgeon to swear there was no disability. The result was continuance of the compensation. Mr. Morley cited one extraordinary case of malingering which came within his own experience. A man had received an injury from which, as he alleged, total blindness had resulted. He was led into court by his wife. Mr. Morley examined him in the ante-room of the court, on behalf of the employer. When giving evidence Mr. Morley said that the man was able to see quite well. Asked whether he had used an ophthalmoscope, he replied No, and for the following reason. When testing the man's eyesight he threw a match on the floor, and asked the patient to pick it up. The patient groped about on the floor near the match, but said he was unable to see it. In the meantime Mr. Morley had knocked down a pin with which the patient had fastened his tie. He then noticed that when the patient was resuming his attire, and so off his guard, he picked the pin up off the floor without the slightest difficulty. These facts being proved, there was judgement for the employer! Dealing with the appointment of medical referees, Mr. Morley said that it was still quite rarely that the services of a medical referee were requisitioned. These gentlemen were not always very competent judges, since they were not yet accustomed to treating cases absolutely judicially. He explained that when the Home Office recently appointed referees it carefully excluded all candidates who, from their connexion with insurance companies or from their position as advisers to big companies, had had extensive experience of this class of work. The

reason for taking this course was to prevent the possibility of a referee having to judge cases in which his own company might be interested; but the result was that many of the men most experienced in examining these claims were excluded. Perhaps the most interesting part of the paper was that which dealt with the effect which the Act has had upon the employment of those who are physically defective. Experience had shown, he said, that in the case of a defective workman, sooner or later the conditions which existed would give rise to complications which might be made the basis of a claim for accident. Insurance companies were already beginning to find out that premiums must be raised unless careful medical examination was insisted on. One large railway company with which he was connected had all candidates for employment examined, and he had instructions to reject any men who had any condition which could conceivably bring about complications from which claims could arise, although their maladies were quite trivial and not incompatible with continued health and hard work for many years. One possible way out of the difficulty, which was undoubtedly telling on the working classes, would be to legalize the process of "contracting out" of the liability. Another suggestion he would make was that the responsibility of the costs of an unsuccessful claimant should be thrown upon the union or the solicitor who had taken up the case if the workman himself could not pay them.

Owing to the interest of the subject, the consideration of this paper was postponed until the March meeting of the society.

ERGOPHOBIA.

SURGEON writes: As a medical examiner under the Workmen's Compensation Act, I have read the article on p. 231 with no little interest. Let me say at the outset that I cannot conceive what employers of labour were about when they allowed such a one-sided Act to become law. Now that they are fully realizing this, they themselves are fast awakening to the fact that soon a condition of things will arise which must seriously interfere with the trade and prosperity of the country. As the Act stands, the employer is nothing but an exploited party to be shot at by all and sundry, a legitimate target to receive the fire, for the most part, of those who are too idle to try to work. In saying this I do not mean to imply that there are such things as honest claims, and that for these the Act is not a right and proper one. But when this is granted there still remains the broad, solid fact that the general tendency is towards a lessened independence in any desire to return to work, and a loss of self-respect in the desire shown to make the term of their incapacity extend to a period long after their condition justifies such a contention; in order to do this, medical certificates have to be produced—a matter about which there is in most cases not the slightest difficulty, especially if it be a club patient, for to withhold means trouble, and that often of a serious nature. Thus the merry game goes on, and the battle rages between fitness and unfitness, the aim, of course, being to extract a lump sum, which is often used neither wisely nor well, until, having got to the end, the interesting invalid thinks the best to resume work. As a medical examiner, I have always tried to impress upon employers that they should act, and not promptly, in all cases in which there is a difference of opinion between myself and the doctor in attendance as to capacity for work; and were a medical assessor appointed, as suggested, to sit with the judge on the demand of either party, no doubt great good would result. The difficulty would be to get a suitable man, one qualified for the work, and at the same time independent enough to give an unbiased opinion. This means a State-aided appointment, with a fairly large retaining salary (which does not obtain at present), and, if thought proper, a reduced fee for each attendance at court. In any case, the amount offered should be such as would make it worth a medical man's while to lay himself out for this particular kind of work.

THE second congress of French-speaking doctors on physiotherapeutics will be held in Paris in April. Among the subjects proposed for discussion are the following: Physical agents (massage, Bier's method, x rays, hydrotherapy) in the treatment of varices and varicose ulcers; clinical and scientific disadvantages of the practice of physiotherapy by empirics; physical agents (electricity, radiography, massage, and re-education) in the diagnosis and treatment of infantile paralysis; physical agents (electricity, Bier's method, diet, light treatment, radium-therapy) in the treatment of acne. The congress is under the scientific patronage of Professors d'Arsonval, and Bonchard, Gariel, Gilbert, Hayem, Huchard, Raymond, and A. Robin, and Drs. Benit Barde, Lucas-Championnière, and Trissier.

THIRD INTERIM REPORT OF THE ROYAL COMMISSION ON TUBERCULOSIS.

THE third interim report of the Royal Commission on Tuberculosis is devoted to the investigations of Dr. F. Griffith on the presence of tubercle bacilli in the milk and faeces of cows not showing any signs of disease of the udder during life.

Commenting on Dr. Griffith's work, the Royal Commissioners remark that they have already, in their second interim report, stated that "a very considerable amount of disease and loss of life, especially among infants and children, must be attributed to the consumption of cow's milk containing tubercle bacilli." But whilst the danger arising from cows affected with recognizable tuberculosis of the udder is obvious, it was, in the opinion of the Commissioners, "undecided what is the danger, if any, attaching to the milk of tuberculous cows in which the udder presents no evidence of disease." This matter has therefore been investigated by Dr. Griffith.

SCOPE OF INVESTIGATION.

The faeces and the milk of naturally tuberculous cattle have been tested by means of inoculation and feeding experiments upon animals. Observations have been made on six milch cows. Three of the animals—B, C, and F—showed clinical evidence of tuberculosis, but in none of the six could any tuberculous disease of the udder be detected during life.

In order to obtain the faeces the action of the rectum was stimulated by the injection into it of air through a sterile glass tube, and the faeces were received directly into a pail, which was applied to the margin of the anal orifice. These precautions were necessary, since in one case, B, there was a purulent discharge from the vagina; and in three cases, B, C, and F, the *post-mortem* examination revealed extensive tuberculosis of the uterus. A portion of the faeces was rubbed up in a mortar with sufficient salt solution to moisten it, and pressed through muslin to form an emulsion. This material was inoculated into guinea-pigs by the intraperitoneal method. Care had to be taken as regards dosage. It was found that 0.5 c.cm. of the emulsion almost invariably caused death from acute peritonitis; but when a smaller dose, 0.05 c.cm., was used all the animals survived the immediate effects of the inoculation. The infectivity of the faeces was also tested by feeding both guinea-pigs and young swine, the latter animals being about 11 weeks old.

The milk of five cows, B, C, D, E, and F, was tested for the presence of tubercle bacilli, strict precautions being taken to ensure absence of contamination during its collection. A metal catheter, connected by pressure tubing to a flask, was inserted into the milk sinus of the udder, a separate apparatus being used for each quarter, and the milk was withdrawn from the udder by the exhaustion of the air in the flask. Before the insertion of the catheter each teat was washed with a solution of perchloride of mercury and with methylated spirit, and the opening was inspected to ensure that no faecal matter was pushed in with the catheter. With the milk thus obtained guinea-pigs, and occasionally rabbits were inoculated. The usual dose given to a guinea-pig was 10 c.cm. of uncentrifuged milk plus the deposit of 20 c.cm. of centrifuged milk. The milk of three of the cows was also administered, by feeding, to young swine.

RESULTS OF EXPERIMENTS.

The following is a summary of the experiments:

COWS MANIFESTLY DISEASED.

Cow B was a shorthorn, and had calved four weeks before the commencement of the observations. She reacted to tuberculin, was in poor condition, and had a short frequent cough. *Post-mortem*, the thorax was found to be very extensively tuberculous, and there was also tuberculosis of the alimentary tract and the uterus. The udder was found to be free from tuberculous lesions. The faeces of this cow were inoculated intraperitoneally into 25 guinea-pigs; 8 of these animals succumbed to septic infection, 1 remained healthy, and the remaining 16 developed tuberculosis. Several guinea-pigs were fed with faeces, but all remained healthy in spite of the fact that they received fifty times the amount of faecal emulsion which readily produced tuberculosis when inoculated intraperitoneally. Four young swine were fed with faeces, the total amount given to the four animals being 19.1 kilograms. They were killed after periods varying from 63 to 100 days subsequent to

the first feeding, and all showed generalized tuberculosis. The milk of Cow B in the first series of experiments was inoculated into 56 guinea-pigs, none of which produced satisfactory evidence that the milk injected contained tubercle bacilli. Subsequently the cow was inoculated with 20 c.c.m. of tuberculin, and the milk was then tested again. Out of 16 guinea-pigs inoculated, 11 developed tuberculosis. Three pigs fed with the milk prior to the inoculation of tuberculin developed no disease.

Cow C, a Jersey, was emaciated and feeble, breathed hard, and had a frequent cough. Her temperature was febrile, and there was no rise sufficient to constitute a positive reaction after the inoculation of tuberculin. *Post mortem* she exhibited severe thoracic tuberculosis; the Peyer's patches of the small intestine contained caseous nodules, and there were several small ulcers in this part of the gut; the uterus was extensively tuberculous. The udder was normal. The faeces of this cow were inoculated into 30 guinea-pigs; 17 of them became tuberculous; the rest died too soon for tuberculosis to develop. Out of 14 guinea-pigs fed with the same material only 1 became tuberculous. The following experiment gives some idea of the large number of tubercle bacilli in the faeces of this cow. One gram of faeces was added to two litres of sterilized water, and 2 guinea-pigs were inoculated intraperitoneally, one with 1 c.c.m., the other with 2 c.c.m. of the mixture. Both animals developed severe general tuberculosis, the former dying in sixty-three days. A young pig, fed with 5.55 kilograms of the faeces, was killed forty-eight days after the first meal, and showed disseminated tuberculosis, with enlargement and caseation of the submaxillary and mesenteric glands. On three occasions the milk of this cow was tested upon guinea-pigs and rabbits; none of the animals in the first batch became tuberculous; on the second occasion tuberculosis was produced in 2 guinea-pigs; and in the third experiment 3 rabbits and 4 guinea-pigs became tuberculous.

Cow F was very emaciated and feeble, and was killed after she had been under observation for a few days. The *post-mortem* examination revealed severe generalized tuberculosis. In the left hind quarter of the udder, in the tissue forming the wall of the main sinus near the teat, there were four reddish-grey, caseating nodules, up to a pea in size. The rest of this quarter and the other three quarters were normal in appearance. The faeces produced generalized tuberculosis in guinea-pigs. The milk was inoculated into 32 guinea-pigs; 11 of these died prematurely; the others developed general tuberculosis, which in many instances was of a particularly severe type. Three pigs died in death in from eighteen to twenty-four days after inoculation.

COWS NOT MANIFESTLY DISEASED.

Cow A was a shorthorn heifer in good condition, and the diagnosis of tuberculosis depended entirely on the positive result of the tuberculin test. When killed, the animal was found to have an enlarged retropharyngeal gland which was cystic, with thick fibrous walls, and filled with breaking down caseo-necrotic substance. In the Peyer's patches of the small intestine there were three grey nodules containing caseous foci, two soft caseous nodules, and a small ulcer in which no tubercle bacilli could be demonstrated. A caseous mesenteric gland, a caseous gluteal gland, and four tubercles in the lungs were also noted. All other organs and glands were healthy. The faeces were used to inoculate and feed 41 guinea-pigs. None of these animals developed tuberculosis. Four other swine were also fed, the total amount of faeces administered being 25.6 kilograms; 3 of these animals proved to be free from tuberculosis; in the fourth the *post-mortem* examination revealed tuberculosis of the submaxillary glands, a caseous focus in one mesenteric gland, four caseating tubercles in the liver, and about thirty on the surface beneath the pleura of each lung.

Cow D was fat and in good condition, the diagnosis of tuberculosis resting entirely on the positive result of the tuberculin test. *Post mortem*, the lungs were found to contain discrete tuberculous nodules, several of which measured about 10 by 6 by 5 cm. On section, these were composed of softening, yellow, caseo-necrotic substance surrounded by fibrous walls. A few of the nodules had ulcerated into the bronchi, in which soft caseous substance was seen, and mucus-pus could be squeezed out of many of the bronchioles. The bronchial and mediastinal glands were enlarged, caseo-necrotic, and gritty. There was no tuberculosis in any other organ or gland in the body. Out of 11 guinea-pigs inoculated with the faeces of this cow 2 became tuberculous; the faeces also produced tuberculosis in 2 out of 3 rabbits inoculated. Two swine remained healthy after feeding with the same material. The milk was tested upon guinea-pigs, but produced no evidence of tuberculosis.

Cow E was in very good condition, but gave a positive reaction to tuberculin. After death there were found in the lungs three small tuberculous nodules, and in the caudal mediastinal gland thirty to forty calcareous nodules up to a pea in size were discovered. In a suprapneal body there was a tubercle the size of a rape-seed in which tubercle bacilli were demonstrated. There was no tuberculosis elsewhere. Dr. Griffith failed to demonstrate tubercle bacilli in either the faeces or the milk of this animal.

GENERAL CONCLUSIONS.

In their review of the experiments summarized above, the Royal Commissioners remark: "The presence of tubercle bacilli in the milk of cows clinically recognizable as tuberculous confirms the opinion we expressed in our second interim report that the milk of such cows must be considered dangerous for human beings. The experiments

which we have carried out with regard to the infectivity of the faeces of tuberculous cows were dictated by knowledge of the fact that dirt of various kinds from cows and the cowshed is almost constantly present in milk as it reaches the consumer. Cows suffering from extensive tuberculosis of the lungs must discharge considerable numbers of bacilli from the air passages in the act of coughing, and some of the bacilli thus expelled may find their way into the milk. But our experiments indicate that the excrement of cows obviously suffering from tuberculosis of the lungs or alimentary canal must be regarded as much more dangerous than the matter discharged from the mouth or nostrils. We have found that even in the case of cows with slight tuberculous lesions tubercle bacilli in small numbers are discharged in the faeces, while, as regards cows clinically tuberculous, our experiments show that the faeces contain large numbers of living and virulent tubercle bacilli. The presence of tuberculous cows, such as B, C, and F, in company with healthy cows in the cowshed, is therefore distinctly dangerous, as some of the tubercle bacilli which escape from their bodies in the excrement are almost certain to find their way into the milk."

LITERARY NOTES.

A THIRD edition of the Hungarian *Pharmacopoeia* is in preparation and will soon be published. The Hungarian portion of the text is already in type; the revision of the Latin text, which has been entrusted to M. Stephan David, a scholar of high reputation, is nearing completion.

In the *New York Medical Journal* Dr. Charles Greene Cusumon gives an account of the career of Benjamin Franklin, from which it appears that he gave considerable attention to the study of medicine. He was the first foreign associate elected by the French Royal Society of Medicine. That society, which was founded in 1776, had among its members at the time such men as Daubenton, Jussieu, and Vicq d'Azyr. In the *Transactions* of the society it is recorded that in 1776 Franklin presented a work by Dr. Perkins, of Boston, entitled *On the Nature and Origin of Epidemic Catarrhal Fevers*. Marat, who, as is now well known, was not a "horse doctor," as Carlyle calls him, but a physician, presented Franklin with a work on physics written by him. When the pretensions of Mesmer were to be examined the Academy of Science named Franklin one of the Commissioners. From a letter written to Sir John Pringle by Franklin it appears that he had used electricity in the treatment of paralysis. To other correspondents he writes on the inoculation of small-pox, and on solvents for stone in the bladder, and he was the author of papers on the cause of the heat of the blood in health and of the cold and hot fits of some fevers; on gout (from which he himself suffered grievously), and of a work entitled, *Some Account of the Success of Inoculation for the Small-pox in England and America; together with Plain Instructions by Which Any Person may be Enabled to Perform the Operation and Conduct the Patient through the Distemper*. This was printed in London by W. Strahan in 1759. It seems from the introduction to have been written in response to a request from Heberden for information as to the success of inoculation in New England.

The literature that in the last few years has been steadily gathering around the name of Napoleon shows no sign of diminishing. It is now announced that the French Society of the History of Medicine is about to institute an exhaustive inquiry as to the state of the great Emperor's health at the time of Waterloo. The investigation, it is stated, will be made by a committee of which the chairman will be Professor Landouzy.

The first part of a new periodical, devoted, as its name—*Archiv für die Geschichte der Naturwissenschaften und der Technik*—imports, to the history of science, has recently appeared. The editors are Drs. Karl von Buchka and C. Schafer of Berlin, H. Stadler of Munich, and Karl Sudhoff of Leipzig. The publisher is F. C. W. Vogel of Leipzig. The *Archiv* will appear at irregular intervals, six parts forming a volume. The language is not limited to German. The first part contains contributions in French and Italian, besides German. The price of each volume will be 20 marks.

In the January number of the *West London Medical Journal*, Dr. S. D. Clippingdale gives an interesting account of Hammersmith quacks in the eighteenth century. He refers to the advertisement of one Neeler, a resident in King Street, which appeared in the *St. James's Evening Post* of November 24th, 1737, for a "noted girdle," the wearing of which would cure all skin diseases, even those of the feet and scalp. Dr. Clippingdale says this magic girdle is probably referred to in the following anecdote of Johnson, which was published in the *Morning Advertiser* of April 23rd, 1776:

As Dr. Johnson and Mr. Boswell were riding upon the Western Road they observed written up over a shop, "Girdles for the itch and all scurvy diseases," upon which the doctor observed, with his usual politeness and humour, "Boswell, if that man would advertise his medicine upon the Northern Road he would make his fortune and do good service to your countrymen."

Then there were two quacks, husband and wife, named Loughterburg, who dwelt on Hammersmith Mall. Both professed to have a miraculous gift of healing, and naturally they proclaimed the fact to the public. They were besieged with crowds of applicants, sometimes, it is said, to the number of three thousand. The treatment was gratuitous, but tickets for places in the crowd were required, and the prices of these found their way into the pockets of the gifted healers. Their method was not limited to the laying on of hands, for Horace Walpole, in a letter to the Countess of Ossory, dated July, 1769, says:

Loughterburg, the painter, is turned an inspired physician. His sovereign panacea is barley-water; I believe it is as efficacious as mesmerism.

A full account of these cures (says Dr. Clippingdale) was published in 1789 by a Mrs. Platt in a pamphlet having the following title: *A List of Cures performed by Mr. and Mrs. Loughterburg of Hammersmith Terrace, without Medicine. By a Lover of the Lamb of God.* The Loughterburgs should have lived in these days when they would doubtless be active members of the movement now being carried on by Mr. James Moore Hickson, the Rev. Percy Dearmer, Bishop Fallows of Chicago, and so many others who would probably take unto themselves the same title which the sacred prophetess of the ex-scene painter assumed. The vogue of the Loughterburgs, it may be surmised, was not long, for the failure of one of their healings led to the storming of their house by an angry mob, and the healers folded their tents like the Arabs and silently stole away. We need not give any "modern instance" to point the moral of the story.

The Clarendon Press at Oxford has within the last few years published a good many medical books—a development which may perhaps be traced to the influence of Professor Osler. Its history may, therefore, be interesting to some of our readers. The following brief account is based on a detailed article which lately appeared in the *Times*: The tercentenary of the birth of Edward Hyde, the famous Lord Clarendon whose daughter became the wife of the Duke of York, afterwards James II, falls on February 18th of the present year. Clarendon was educated at Oxford, and in 1660 was elected Chancellor of the University. After his fall in 1667 he resigned the office. The first edition of his *True Historical Narrative of the Rebellion and Civil Wars in England* was published by the Oxford University Press between 1702 and 1704. With the profits derived from the publication the university built, in 1713, a new printing house near the Sheldonian theatre, where before that date a large part of the printing work of the university had been done. The name of Clarendon was attached to the new building. The copyright of the *History* remains perpetually in the possession of the university, to which the rest of Clarendon's MSS. were presented in 1753 by his great-granddaughters. In 1860 the profits of the *History* amounted to £10,000. The Clarendon trustees decided to employ the money to help the university to meet the demands of physical science; and in 1872 the Clarendon Laboratory for Experimental Philosophy was erected as part of the University Museum. The name of Clarendon is thus preserved at Oxford by the Clarendon Building, the Clarendon Press, and the Clarendon Laboratory. The Clarendon Building was the Clarendon Printing House from 1713 to 1830, when the new printing house was built in Walton Street, now known as the Clarendon Press. The Clarendon Building has still some

connexion with the Press, inasmuch as the delegates of the Press hold their meetings in the room originally designed for that purpose. The Clarendon Building has just undergone an elaborate series of repairs, and at the present date its refaced walls give something like the impression they must have been made in 1713.

Nova et Vetera.

MODERN MEDICAL APHORISMS.

THE "Aphorisms" of Hippocrates breathe the highest spirit that should animate the practitioner of the art of healing and the clinical observer. In contrast with these may be placed the aphorisms of La Mettrie, the physician (seldom consulted, as Carlyle says) of Frederick the Great, which breathe the spirit of the shrewdest worldly wisdom. We cite them, not so much for the edification as for the amusement of our readers. Here and there, however, there are hints which may be useful to some simple-minded brethren who, for the lack of the knowledge that is generally learnt only by bitter experience, may find themselves at a disadvantage as compared with men much inferior to themselves. They are likely to be helpful to men of the type of "Lydgate," drawn with a master hand by George Eliot in *Middlemarch*. La Mettrie says:

Distrust your professional brother—*medicus medicum edit*. If you are in a fix lay the responsibility on the backs of the consultants. Never try an active remedy on a person of high position; it is a better that a great lord should yield to human destiny, even prematurely, than that the doctor should be compromised. In the case of consultations try to arrive on the scene a quarter of an hour before the others, in order that you may see the patient alone and gain his confidence while seeming to study his disease. Visit the patient during the time the remedy is displaying its effects; make some small change in the mode of administration; thus you will supplant not only one or two brother practitioners, but the whole Faculty. Take care to stand well with the surgeons and pay court to the apothecaries. Do not give medicines to those who do not like them. In the case of the others order only drugs that are anodyne, well known, and have not a bad taste. Do not pay too many visits; this would gain for you the reputation of being eager for fees. Unpunctuality will be excused if you plead the number of people you have to see. Always have the air of being busy. If you are asked out to dinner, arrive late and look as if you had been hurrying, and arrange that you shall be sent for at dessert. If women discuss the causes of a disease, do not contradict them but agree with them. If women advertise you, your fortune is made. Above all do not despise the support of ladies' maids and nurses.

These maxims will doubtless seem cynical to young men with lofty ideals of their profession. Some of them recall the arts of Sawyer late Knock-em-off, in which he was anticipated by no less a man than John Huxham, from whom, *via* Ferdinand Count Fathom, Dickens may have borrowed them. The touch as to making a slight change in the mode of administration reminds us of the window or arch which that eminent architect, Mr. Pecksniff, introduced into the plans drawn by his students, thereby stamping them with his own genius. We have heard a well-known physician, now no more, praised by lady patients for the "elegance" of his prescriptions; these contained water in the same proportion to the medicine as the sack bore to the bread in Falstaff's tavern bill. We have seen diagnostic *coups de theatre* performed at the bedside—after careful preparation beforehand. In fact, there is nothing in La Mettrie's aphorisms but what is an important part of what is called "experience" in medical practice; and a man is not necessarily to be condemned as dishonest who uses these means to make real knowledge tell. If he has no knowledge, of course, that is another matter. It has been said, *Homo homini lupus*. This is certainly not infrequently true in regard to doctors. We complain—and justly enough—of the public. But after all, our worst enemies are those of our own household.

Another set of aphorisms, credited to Dr. Amédée Latour, may be compared with those we have cited. They are to the following effect:

The physician fusses, but it is the disease that leads him about. Life is short, patients are hard to please, the brethren are deceptive. Practice is a field of which worldly wisdom is the manure. A patient is like flannel; neither the one nor the other can be left for a moment without danger. The patient who pays his doctor is exacting; the patient who does not pay

him is a despot. Simplicity, modesty, truth! Charming things—everywhere else than by a patient's bedside where "simplicity" is taken to be hesitation: "modesty," diffidence of oneself; "truth," roughness. Medicine is the only profession in which lying is a duty. The doctor who goes away has the same chance as a lover of finding himself replaced by a substitute on his return.

As in the case of the other maxims already quoted, we do not wish to be understood as recommending these as embodying the highest perfection of professional morality. But that they are profoundly true few men who know the world will deny, and they may be commended to enthusiastic youths as useful prolegomena to all introductory addresses.

Medical News.

SIR WILLIAM GOWERS will give a lecture on unilateral optic neuritis from cerebral tumour at University College Hospital on Wednesday next at 4 p.m.

HIS EXCELLENCY THE LORD LIEUTENANT has accepted the invitation of the President and Fellows of the Royal College of Surgeons in Ireland to the annual college dinner on Saturday, February 20th.

HIS MAJESTY THE KING has been pleased to grant permission to Dr. George Ogilvie to accept and to wear the Insignia of Knight of the Royal Order of Isabel la Catolica, conferred upon him by the King of Spain.

DR. F. M. SANDWITH, Gresham Professor of Physic, will give four lectures at Gresham College on February 9th, 10th, 11th, and 12th, at 6 p.m., in which he will discuss Malta fever, diphtheria, and the life-work of Pasteur.

THE annual dinner of the Chelsea Clinical Society will take place at the Gaiety Restaurant, Strand, W.C., on Thursday, March 4th. Particulars can be obtained from Dr. K. R. Collis Hallows, 104, Buckingham Palace Road, S.W.

The Lettsomian Lectures at the Medical Society of London will be delivered by Dr. Sidney Martin, F.R.S., on February 1st, 15th, and March 1st, at 9 p.m. on each evening. The subject of the lectures is functional disorders of the stomach and intestines, their diagnosis from organic disease and treatment.

THE French Congress of Scientific Societies will be held this year at Rennes. Among the subjects proposed for discussion are: The relations of sociology and anthropology; healthy and cheap dwellings; alcoholism—the evil, its causes and remedies; tuberculosis and the means of avoiding contagion; high altitude and seaside sanatoriums; methods and disinfection against contagious diseases, and the results obtained in towns, rural districts and establishments in which disinfection is practised; the water supply of towns—the contamination of subterranean lakes; leprosy and pellagra in France; the part played by insects and especially the common fly in the dissemination of contagious diseases; hygiene of the school child.

IN the course of his presidential address to the Royal Meteorological Society on January 20th, Dr. R. H. Mill remarked that it was popularly held that sunshine, heat, and dryness were necessarily good, and rain and cold necessarily bad. These current and erroneous beliefs affected the meteorological departments maintained by many municipalities so strongly that to be above the local average in the "bad" elements and below it in the "good" was held to be a disgrace never to be acknowledged if it was possible to deny it. He had even heard of instances in which reports were suppressed in order to obviate misconception, and of others in which instruments were moved to obtain more agreeable records.

THE first Negro Congress on Tuberculosis was (we learn from the *Medical Record*) held at Tuskegee, Alabama, during the third week in December, 1908. On the opening day, "Health Sunday," seven meetings were held, and in the course of the next six days the 1,500 students of the Tuskegee Institute attended the evening meetings, at which addresses, illustrated by stereoscopic views, were delivered. It was decided to establish a permanent tuberculosis committee at Tuskegee, with similar committees at other leading negro institutions. A propaganda will be set on foot in the press that circulates among the negro population, and the State Boards of Health will be asked to supply printed matter about the disease and the means of preventing its spread.

A REPORT by Dr. Masson on the administration of the isolation hospital and camp during the recent outbreak of

bubonic plague in Trinidad has been issued. In the period May 30th to September 28th there were 19 cases with 15 deaths, giving a death-rate of 78.9 per cent. This would indicate that the disease was of a virulent strain, though no frankly pneumonic cases were seen. The report says little about infection of the rats in the town, but this will probably be dealt with by the medical officer of health later. It will largely depend on this whether the disease will break out again, and Thompson's report on a seventh outbreak of plague at Sydney should be well studied by the authorities in Trinidad. There is nothing unusual in the clinical details and pathology of the cases reported on: they are typical of ordinary bubonic plague.

LORD ROBERT CECIL will preside at a dinner of the staff and students of the London School of Clinical Medicine at the Savoy Hotel on Friday, February 19th. Among those who have promised to attend are Sir Thomas Barlow, Bart., K.C.V.O., Sir W. J. Collins (Vice-Chancellor of the University of London), Sir William Watson Cheyne, C.B., Sir William Church, Bart., K.C.B., Dr. J. F. Goodhart, Admiral Swinton C. Holland, Sir Malcolm Morris, K.C.V.O., Sir Richard Douglas Powell, Bart., K.C.V.O. (President of the Royal College of Physicians), Colonel W. B. Leishman, R.A.M.C., Inspector-General James Porter, C.B. (Director-General of the Medical Department of the Royal Navy), Lord Ridley, Mr. A. W. Mayo Robson, Sir Thomas Smith, Bart., K.C.V.O., and Professor Starling.

A QUARTERLY court of the directors of the Society for Relief of Widows and Orphans of Medical Men was held on January 15th at 5.30 p.m., Dr. Blandford, president, in the chair. Fifteen directors were present. The deaths of three members were reported, among them being that of Sir Henry Pitman, a vice-president of the society. A vote of condolence to Lady Pitman was passed from the chair. Three new members were elected. A sum of £528 had been distributed among the annuitants of the charity as a Christmas present, each widow receiving £10, each orphan £5, and each orphan on the Copeland Fund £5. Since the last court one of the annuitants of the charity had died: her husband had paid in subscriptions £35 12s., and died in 1855: since that date his widow received in grants from the society the sum of £5,300. This is a most striking instance of the advantages of joining the society. The sum of £1,242 10s. was voted for half-yearly grants to the widows and orphans at present on the books of the society. Relief is only granted to the widows and orphans of deceased members, and during the past three months five letters had been received from widows of medical men left penniless asking for relief, but this had to be refused, as their husbands had not been members of the society. Membership is open to any registered practitioner who at the time of his election is residing within a twenty miles' radius of Charing Cross. Full particulars and application forms for membership may be obtained from the secretary at the offices of the society, 11, Chandos Street, Cavendish Square, W. The invested funds of the society now exceed £100,000.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on January 15th, Dr. de Havilland Hall in the chair. In accordance with custom, at the first meeting of the year special reports on the cases of those members who seem to be unlikely to be ever able to resume professional work were examined, when it was determined to make provision for chronic illness. It was foreseen that this would involve a considerable outlay, but the number of chronic cases has increased more quickly than was anticipated, and now, numbering over 40, they require an outgo exceeding £3,000 per annum, and at each valuation of the society's business a substantial special reserve has been made in respect of them. Five years has elapsed since the last valuation, and the actuaries are now engaged in estimating the necessary reserves for the business. The amount required for the chronic cases is growing very large, and this part of the business bids fair to become one of its most important features. Although last year the ordinary sickness claims amounted to rather more than the expectation, they have generally shown a margin in favour of the society. When the report is presented to the members at the annual general meeting to be held in May next, it will be found that both during the year 1908 and during the quinquennium of which it is the final year, the financial strength of the society has grown in a satisfactory manner. Prospectuses and all further particulars on application to Mr. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

British Medical Journal.

SATURDAY, JANUARY 30TH, 1909.

TUBERCULOUS MILK WITHOUT UDDER DISEASE.

THE Third Interim Report of the Royal Commission on Tuberculosis (p. 291), based on the experimental inquiries of Dr. F. Griffith regarding the presence of tubercle bacilli in the milk and faeces of cows affected with tuberculosis, but without disease of the udder, affords an important practical corroboration and amplification of the findings published by the Royal Commissioners in 1907. They then stated, in their Second Interim Report, that "there can be no doubt but that in a certain number of cases the tuberculosis occurring in the human subject, especially in children, is the direct result of the introduction into the human body of the bacillus of bovine tuberculosis; and there also can be no doubt that in the majority at least of these cases the bacillus is introduced through cow's milk. Cow's milk containing bovine tubercle bacilli is clearly a cause of tuberculosis, and of fatal tuberculosis in man." After pointing out that the demonstration of tubercle bacilli in cow's milk may sometimes be a matter of difficulty, the Royal Commissioners proceed: "There is far less difficulty in recognizing clinically that a cow is distinctly suffering from tuberculosis, in which case she may be yielding tuberculous milk. The milk coming from such a cow ought not to form part of human food, and indeed ought not to be used as food at all. Our results clearly point to the necessity of measures more stringent than those at present enforced being taken to prevent the sale or the consumption of such milk."

In this clause of their report the Royal Commissioners in no way indicated that the danger was confined to such tuberculous animals as exhibited recognizable disease of the udder. Farmers, however, have been desirous of putting this limited interpretation upon the Commissioners' verdict, and have been endeavouring to find some support for this attitude by appeal to statements contained in the report of a previous Royal Commission on Tuberculosis (1895). This Commission remarked that "according to our experience, then, the condition required for ensuring to the milk of tuberculous cows the ability to produce tuberculosis in the consumers of their milk is tuberculous disease of the cow affecting the udder. It should be noted that this affection of the udder is not peculiar to tuberculosis in an advanced stage, but may be found also in mild cases." An even stronger expression of opinion in favour of the farmers' view was published by Sir John McFadyean in 1901.¹ He then stated that "not every cow that is tuberculous gives milk containing tubercle bacilli. It is true that opinions with regard to this point are not absolutely unanimous, but there is ample evidence to justify the assertion that, as a rule, the milk is not dangerous until the udder itself becomes diseased. The experi-

ments pointing to an opposite conclusion form only a small minority, and the results obtained in most of them were probably due to carelessness on the part of the experimenter. . . . The important question, therefore, is not what proportion of milch cows are tuberculous, but what proportion of them have tuberculous udders."

The Third Interim Report of the present Royal Commission removes ambiguities and previous misconceptions on this point. Dr. Griffith's researches, fully accepted and endorsed by the Royal Commissioners, conclusively show that both the milk and the faeces of cows clinically tuberculous, but with no disease of the udder, are liable to contain living and virulent tubercle bacilli, and often contain them in very large numbers. Every person acquainted with the conditions which usually obtain in cowsheds used for milking purposes will readily understand that the process of milking is conducted in such a way as to make contamination with particles of faecal material the rule rather than the exception; the danger of introducing tubercle bacilli into the milk when these bacteria occur in the intestinal tract is, therefore, always present, and is a grave menace to the health of the consumer.

Hitherto English authorities have lagged behind investigators in other countries, notably Germany and America, in realizing these dangers. In 1899, for example, Rabinowitch and Kempner published an important investigation on the milk of cows reacting to tuberculin. They examined the milk of 14 animals, only one of which exhibited disease of the udder manifest by physical examination; but in ten out of these fourteen they succeeded in proving that tubercle bacilli were present in the milk which the animals yielded.

In 1907 Schroeder and Cotton published in a report to the American Bureau of Animal Industry (Bulletin, No. 99) an interesting series of cases in which they showed that tubercle bacilli are disseminated with the faeces of tuberculous cattle, and that this dissemination occurs not only with visibly diseased animals, but also with those in which the diagnosis of tuberculosis depends entirely on the application of the tuberculin test. In the same year Dr. Mohler, Chief of the Pathological Division of the American Bureau of Animal Industry, reviewing the evidence which had been accumulated on this subject, wrote as follows: "That milk coming from a tuberculous udder is capable of transmitting the infectious principle is conceded by all who have given the subject any consideration. It has been equally established that in advanced generalized tuberculosis the udder may secrete tubercle bacilli without showing any indication of being affected. Careful experiments performed by trained and eminently responsible investigators have also demonstrated beyond reasonable doubt that tubercle bacilli at certain times may be present in the milk of cows affected with tuberculosis to a degree that can be detected only by the tuberculin test, so that in a herd of cows in the various stages of tuberculosis it is to be expected that some of them will secrete tuberculous milk, which, when mixed with other cows' milk, makes the entire product dangerous." In view of the fact that Dr. Mohler's own experimental investigations on this subject are justly recognized in America as being thoroughly reliable and of high practical significance, this expression of his opinion is well worth consideration.

We are glad to find that the serious attention of bacteriologists in this country has now been turned to

¹ Address on Tubercle Bacilli in Cow's Milk as a Possible Source of Tuberculous Disease in Man. Trans. Brit. Congress on Tuberculosis, Vol. 1, p. 83.

the importance of these problems. The number of cows investigated by Dr. Griffith is relatively small, but his results are positive, and the conclusions deducible from them are unambiguous; taken in conjunction with the work already placed on record in other countries, they furnish an incontrovertible proof that the milk of clinically tuberculous cows is, even in the absence of udder disease, a serious danger to human health.

With regard to cows apparently in perfect health but yielding a positive reaction to the tuberculin test, Dr. Griffith's experiments only deal with three animals. In two of these he was able to demonstrate the presence of tubercle bacilli in the faeces, but in none of the three has he been able to state that they occurred in the milk. From such a limited number of cases it is impossible to generalize; others who have made more extensive observations apparently find that tubercle bacilli may occur not only in the faeces but also in the milk of these physically healthy but tuberculin-reacting animals. A very much larger accumulation of experimental statistics must be provided before reliable conclusions can be drawn as to the magnitude of this danger. Nor does it appear possible, at least until the extensively tuberculous beasts have been eliminated from our milch herds, to attempt to enforce the exclusion of animals which are in the early stage of the disease, where diagnosis can only be established by the tuberculin test.

Our Government has been expending money on scientific research, which has led to results of immediate practical importance. It now rests with our legislators to provide a basis for administrative measures which shall safeguard the public from the risks of contracting disease by the consumption of milk obtained from cows seriously affected with tuberculosis, whether or no the udders of these animals be recognizably tuberculous. This requirement is obviously necessary; but in view of the appallingly extensive prevalence of tuberculosis amongst cattle, it does not appear possible at present for the Legislature to proceed further.

THE STANDARDIZATION OF DISINFECTANTS.

WITH unfailing regularity the medical journals of this and especially other countries publish articles on new antiseptics and disinfectants. From time to time fresh claims are put forward for this or that drug or compound, until the number of preparations for which disinfectant properties are claimed bewilder the medical, to say nothing of the lay, mind. In addition to the difficulties which arise from the actual number of preparations, that arising from the want of uniformity of methods of standardization has to be taken into account, and it is in regard to this matter that the greatest confusion has arisen. But even if a uniform method were introduced into daily practice, there would be no guarantee of the value of any given disinfectant, unless it could be scientifically proved that the method really measured, within the limits of reasonable experimental error, the disinfectant capabilities of substances under the conditions in which such disinfectants were used.

This want of uniformity led Dr. Martin, Director of the Lister Institute, to organize some two years ago a thorough investigation of the subject. The nature of the process of disinfection was studied, in the first instance by Miss Chick, in the institute's laboratories,¹

with the result that a complete analogy was found to exist between the process of disinfection and a chemical reaction. This research enabled the author to enunciate certain general laws of disinfection, and to determine how far the process is modified by variations in the concentration of the bacteria and of the disinfectant, and in the temperature at which the tests were applied. The laws thus determined were found, rather unexpectedly, to be capable of being expressed by a simple formula.

Starting from the foundation afforded by this accurate knowledge, Dr. C. J. Martin and Miss Chick proceeded to study the means of applying standards to disinfectants. Of the methods hitherto used in bacteriological laboratories for standardizing disinfectants, the thread method of Robert Koch, the garnet method of Paul and Krönig, and the drop method known as the Rideal-Walker represent those with the most scientific basis. The trustworthiness of Koch's method of testing the antiseptic by applying it to silk threads on which anthrax spores have been dried is challenged, on the ground that it demands a higher standard of efficiency than is necessary. Apart from this, a perusal of the paper to which we have referred demonstrates other defects in this method. Again, the garnet method cannot be accepted as satisfactory, as the conditions are artificial and not in the least analogous to those obtaining in practice. The Rideal-Walker method, while superior to the two others, needs, in the opinion of the authors, modifications to satisfy the requirements of a scientific test. In the Rideal-Walker method the temperature was kept more or less constant, and the number of bacteria per unit volume as well as their degree of resistance was not allowed to vary. Martin and Chick insist on the importance of keeping these conditions as constant as bacteriological methods will allow, and, further, lay great stress on the necessity of making the time of disinfecting the same. The constants employed in their experiments are, therefore, temperature, concentration of bacteria, virulence and resistance of bacteria, culture medium, and time.

It is shown that among the vegetative organisms considerable variations in resistance occur, and the resistance of virulent germs is not quite identical with that of old strains of the same micro-organism. The resistance to phenol of spore-forming microbes is from 17 to 25 times greater than that of vegetative organisms. Practically, phenol and emulsified disinfectants are too feeble for use with sporing germs, and only the metallic salts are efficient germicides for this purpose.

The next problem attacked—the determination of the conditions under which the test, with constant temperature, number of bacteria, medium and time, is to be carried out—opened up a much more debatable chapter, and the solution offered, even if not absolutely ideal, is one which must be regarded as highly satisfactory. To fix the germicidal value of a disinfectant by its action in aqueous suspensions would practically be to limit the applicability of the method to the disinfection of surgical instruments. Disinfectants are, however, mainly used for the treatment of infected excreta, sewage, etc., when, as in nearly all other circumstances under which disinfectants are used—such as the cleansing of wounds, the disinfection of furniture and dust-laden objects, and the streets—the disinfectant has to act in the presence of organic matter. Objections have been raised to testing disinfectants in the presence

¹ Harriette Chick, D.Sc., and C. J. Martin, M.B., D.Sc., F.R.S., *The Principles Involved in the Standardization of Disinfectants and the Influence of Organic Matter upon Germicidal Value*, *Journal of Hygiene*, vol. viii, No. 5, 1908, pp. 655-697. See also p. 286 of this issue.

faecal matter, and the authors state that when employed in their natural condition marked variations occur, which destroy the value of the test. Dried and finely divided faeces, however, were found to yield constant results, and it was discovered that it was the particulate condition rather than the composition which was of moment.

The experiments reveal some interesting facts with regard to the germicidal values of the various types of disinfectants. Taken broadly, disinfectants may be divided into three classes: The metallic salts, the dissolved phenols, and the emulsified tar acids. In comparing the phenol coefficient in the presence of organic matter of these groups, or rather of certain types of these groups, with the phenol coefficient when tested in water, striking differences were met with. The action of the metallic antiseptic salts, as would have been expected, on organic matter greatly interfered with the action on the bacteria and the concentration of mercuric chloride required to fulfil the requirements of the test in the presence of dried faeces was ten times that needed when water was used. Miss Chick had previously shown that the concentration of Hg ++ ions, and not that of the mercuric salt determines the germicidal power. This observation, however, does not indicate that the efficiency of mercury is lessened ten times by the presence of organic matter, since the concentration of mercury ++ ions is only increased slightly under these conditions. At the other extreme, the phenols only lose about 10 per cent. of their efficiency in the presence of faecal matter. Between these two extremes come the emulsified tar acid preparations and the soluble cresols. The finer the emulsion the greater is the loss of germicidal efficiency in the presence of faecal matter. In other words, all forms of organic matter appear to have the power of lessening the efficiency of disinfectants, the diminution being least marked in the phenols and more marked in fine emulsions of the tar acids than in the coarse emulsions. The authors explain this loss of efficiency on physical and not on chemical grounds. The loss is to a great extent due to adsorption of the emulsion upon the surfaces of the particles of organic material. The same process appears to play an important part in the actual disinfecting action of the emulsions. In another paper,² the same authors investigate the germicidal action of the tar acid preparations as emulsions and as solutions. The active principles of these preparations when dissolved have less disinfecting power than they possess as emulsions, and this was shown to be due to the adsorption of the emulsified tar by the bacteria.

Critics will search for objections to the method of standardizing disinfectants described by Drs. Martin and Chick, for there can be no doubt that if introduced as a normal standard, many reputed disinfectants must lose much of their reputation. The objection to the presence of faecal matter is certain to be raised, as it has already been raised. But no valid argument can be set up if the results obtained by these most careful and capable workers are confirmed. It is to kill germs in the presence of faecal matter that disinfectants are chiefly required, and dried faecal material from different sources has yielded approximately the same results. No rational argument can be adduced against making the temperature and time constants,

since every scientifically-minded person realizes that no workable results can be obtained with more than one variable. No matter what inconveniences may be caused by the upsetting of old ideas and the introduction of new ones, the work is of the utmost importance, and must be regarded as worthy of full consideration by all those concerned in hygiene, since the welfare and safety of the public in no small measure depend on the answer to the question, What is the best disinfectant to be used for a specific purpose?

THE BRITISH MEDICAL BENEVOLENT FUND.

THE British Medical Benevolent Fund deserves the strongest support of the profession and of the public. To bring this home to both is the object of the meeting to be held on February 9th at the Royal College of Physicians. The chair will be taken by the President of the Fund. An address will be delivered by the Right Reverend the Lord Bishop of Oxford, who will be supported by the Right Honourable the Lord Mayor of London, the President of the Royal College of Physicians, and others. Better representatives could not have been found. The Bishop of Oxford is the son of Sir James Paget, who was for many years the President of the Fund. The Lord Mayor is the recognized leader of all national movements in the cause of charity, while Sir John Tweedy and Sir Richard Douglas Powell well represent the medical profession. The Fund was founded in 1836, so that for upwards of seventy-two years it has continued its beneficent work. It has slowly accumulated invested funds out of the income of which it now supports 126 annuitants and spends in this department about £2,500 annually. No candidate is eligible for an annuity till past the age of 60 years. Many most distressing cases, however, occur at a much earlier age, and for these means of relief have to be found in the subscriptions and donations of the year. These fluctuate and can only be approximately forecast. For this reason the grant department of the Fund is a constant anxiety to the managers, for the Fund cannot spend what it has not got; its capacity for good is limited by the contributions of the year. If every medical man would make even a small subscription every year the income could easily be doubled. The need for this Fund is most strongly recognized by those who themselves know best the hard struggles of early professional life, and it is from the medical profession itself that the main support of the Fund comes. Little is given by the public at large. Yet there is no profession which does so much for the public, in public and in private, with so little or no remuneration. The medical profession has therefore a just claim upon public consideration which no other profession can make in equal degree. To bring this prominently forward is the second object of the meeting. The profession itself can show that it is in earnest, not alone by contributing as freely as it can afford, but also by using its influence in every way that offers to bring the claims of the Fund before those of the public who are likely and able to help it. There is no doubt that the work and objects of the Fund only require to be known and realized for the financial support which is so necessary to be forthcoming. Contributions may be sent to the Honorary Treasurer, Dr. Samuel West, 15, Wimpole Street, London.

"PRAYER AS AN INSTRUMENT OF MURDER."

OUR conjecture as to the sex of the writer of the extraordinary document published in the JOURNAL of January 23rd was correct. "M. Cowan" turns out to

² Harriette Chick, D.Sc., and C. J. Martin, M.B., D.Sc., F.R.S., A comparison of the Power of a Germicide Emulsified or Dissolved, with an Interpretation of the Superiority of the Emulsified Form, *Journ. of Hygiene*, 1908, Vol. viii, No. 5, pp. 699-703.

be a woman who is described as "an Irish lady of means," and who is said to be a member of the London Antivivisection Society. Mrs. Cowan herself, according to a correspondent who is quoted by the *Observer*, is quite unrepentant. She says, however, that she does not pray for the death of the vivisector but for his "removal." Yet she speaks of a vivisector "dropping," apparently as the result of "earnest prayer." "Removal," it may be remembered, was the euphemism employed by the "Invincibles," who vainly tried to murder Mr. W. E. Forster but succeeded in "removing" Lord Frederick Cavendish and Mr. Burke. Mrs. Cowan's idea of "removal" is, she explains, slight paralysis or the inheritance of a fortune that would enable the vivisector to settle down in the country. Well, Pasteur was more than slightly paralysed and yet continued his work, while several prominent vivisectors are men of considerable private fortunes that would enable them to live in idleness if the thirst for knowledge did not consume them. Mrs. Cowan obviously knows as little about men of science as she does about their work. It is amusing to note how the antivivisectionists are tumbling over each other in their eagerness to repudiate this too candid member of the fraternity. Mr. Sidney Trist states that his society is in no way responsible for the circular, the issue of which it deplors. Miss Woodward, Honorary Secretary of the Society of United Prayer for the Prevention of Cruelty to Animals, declares that it is highly unlawful to pray for any one's death. She goes on gravely to say that Mrs. Cowan's letter was considered at the last committee meeting of the society, "when one of our members, Miss Burgess, remarked very truly that an unrepentant vivisector dead might do more harm to the community than a living vivisector. We can control the actions of the living, but we do not know what evil influences may be set at work by the uncontrolled spirits of the dead. It is at least a curious fact that our work was never so severely attacked as shortly after the death of several well-known vivisectors." This is an aspect of the vivisection question which is quite new to us, and opens a new vista of enterprise for the opponents of that method of research. Mr. Stephen Coleridge, in a characteristic letter, states that both he and his society are entirely unconnected with the circular. He professes, however, to be afraid lest its transmission to the vivisectors may not possibly lead to retaliative efforts of a similar nature having for their object his removal, and he appeals to all who support his efforts to defend animals from vivisection to make precatory efforts in his defence in order that he may not fall under the malign influence created by the force of malevolent suggestion which may possibly be exercised against him by the vivisectors and by Lord Cromer's earnest associates in the Research Defence Society. Is it that he might be better able to guard himself against this "malign influence" that Mr. Coleridge recently applied to be enrolled as a member of the society? But Mr. Coleridge may be comforted; no one but himself takes him quite seriously, and vivisectors have no time to spare for the contemplation of his devices to keep himself well in focus on the stage whereon he struts and frets his hour, amid so many jealous rivals, for the admiration of the populace. For instance, there is Mr. Bernard Shaw, whose clowning, though poor enough in itself, is more amusing than the Malvolio-like solemnity affected by Mr. Coleridge. Mr. Shaw says "the genuine vivisectionists would be the last people in the world to protest against an experiment so interesting, so important, and so thoroughly scientific in method." Mr. Shaw's notion of scientific method may be gathered

from his style of argument on the many subject with regard to which he so often comes forward to enlighten the public mind. We can assure him that no "genuine vivisectionist" would object to being prayed against by persons of the type of Mrs. Cowan. But fanatics do not always confine themselves to prayer; and, assuming that Mrs. Cowan is as harmless as she is silly, there are, as we have pointed out, persons to whom what Mr. Coleridge calls her "minatory suggestions" might move to the use of more carnal weapons.

PHYSIO-THERAPY.

CONSIDERING the great developments that have taken place during the last ten years in the application of physical means to the treatment of disease, it would be surprising if in Germany, where every department of professional study possesses its special organ, physical treatment should be content to remain unrepresented. Special establishments with all the necessary apparatus for the physical treatment of diseases have been opened in many of the great centres of medical teaching, and the new *Jahrbuch* devoted to physical methods of treatment is edited by Professor E. Sommer, the able Director of the Physical Polyclinic at Zurich.¹ Probably one reason why the value of these means of treatment has been more generally recognized by the medical profession in Germany and German-speaking countries than elsewhere has been the great popular success of the methods advocated under the name of *Naturheilkunde* or *Natural Methods of Healing*, which include practically all means of treatment except the administration of drugs. As the so-called nature-curers are for the most part unqualified and irregular practitioners, it is highly desirable to let the public know that the profession takes account of and employs in a scientific manner all that is valuable in their system. There is ground to fear that if the medical profession in this country stands apart from the scientific use of physical means these will fall into lay hands and be made a cover for the quack, instead of being under the direction of regularly educated scientific practitioners who are not only conversant with their practical application but have studied scientifically the diseases for which they are suitable and are able to give rational reasons for their use. Some of these means have not received from us the attention they deserve, and are regarded with prejudice by many who have heard of them only in association with some objectionable form of quackery. This is especially true of what may be called *medico-mechanics* or the treatment of disease by mechanical forms of massage and movement, often spoken of as the system of Zander. Zander Institutes for the treatment of disease by mechanical means exist in most large centres of population and the chief health resorts of the Continent, but in England the establishment at Bath is almost the sole example. The *Yearbook* contains articles on the treatment of disease by baths, including mud-baths and the use of "fango," a volcanic mud, electro-therapeutics, medical gymnastics, sun-baths, hydrotherapy, massage, light treatment (said to be superior to radium), and other rays, and high-frequency currents. Dr. Jungmann gives a critical account of the progress in the use of light in the treatment of disease, and describes the various modifications, rational or fanciful, which have been introduced into it, not always with benefit. Kromayer and Dyck have made out a good case for the quartz lamp invented by the former; they claim, not

¹ *Jahrbuch ueber Leistungen und Fortschritte auf dem Gebiet der physikalischen Medizin*. Begründet und herausgegeben von Professor Dr. Ernst Sommer, Direktor der Universitätsklinik für physikalische Therapie in Zurich. 1. Jahrgang. Leipzig: Otto Nönnich. 1908. (Roy. 8vo, pp. 440. M.10.)

only that it is simpler, but also, that cases have been cured which had been unsuccessfully treated by the Finsen lamp, that the duration of treatment is generally shorter, and that good results have been attained not only in lupus but in naevi, alopecia areata, and acne rosacea. Professor von Leyden of Berlin has contributed a short article in which he urges that the modern physician must be prepared not only to prescribe drugs, but to correct hygienic mistakes, to regulate diet, modify surroundings, and recommend occupation, to employ apparatus for the application of light, heat, cold, or electricity, or medico-mechanics; to send his patients to special places for treatment, to homes of rest and sanatoriums, to concern himself with insurance schemes against sickness, accidents, and old age; in fact, to consider many questions with which formerly he had nothing to do. It is impossible to stand aside and to regard these matters as outside the proper sphere of medical practice. Physical methods are with us, and ignorance of them or refusal to employ them can only injure the medical profession.

LOW LIVING AND HIGH RENTS.

At an inquest in Southwark on December 18th, 1908. Dr. F. J. Waldo, the coroner, contrived, by apt questions to the witnesses, to bring into strong relief the difficulties suffered by the poor in the matter of finding living accommodation at a reasonable price. The child on which the inquest was held died from tuberculosis, and was one of a family of seven persons—father, mother, and five children—occupying a small house of two rooms. This was furnished by the landlord after a fashion, but the whole family slept in one room. The average income of the family—the father being often out of work—was 14s. 6d. a week, and out of this small sum no less than 9s. 4d., or far more than 50 per cent., went in rent. High as is the sum, it appears, nevertheless, to be a smaller rent per room than is frequently paid for corresponding accommodation in the same locality. One reason why the rents of such houses and rooms are so very high as compared with the means of those who occupy them is that they are often farmed by some small capitalist in the neighbourhood. Buildings for the working classes, such as are commonly erected, either through private enterprise or by municipal authorities, are intended only for persons in possession of furniture, and no attempt, so far as we are aware, has been made to cater for those who have no capital wherewith to furnish a home. Houses and rooms of the character described at this inquest presumably come under the tenement-by-laws of the borough council, and Dr. Dennis McCarthy, who in the course of his evidence in the case gave some striking evidence as to the evils of subletting, said that the house in which the deceased lived was fairly clean, but there would appear to be no special machinery for supervision, and it is not clear that the by-laws are so constructed as to prevent overcrowding within them. Clearly the public health cannot reach a desirable standard so long as there is such an immense disproportion between rent and income in the case of a large section of the less well-to-do working classes, for even the physical difficulty of supporting life on the small income which remains must be immense, and the moral atmosphere induced must be as eminently favourable to alcoholism as it is inimical to cleanliness and sound living of every kind. So long as any considerable portion of the population continues to live in such conditions there must be plenty of scope for the energies of the Mansion House Council on the Dwellings of the Poor, to which attention was recently drawn in these columns.

"ARTIFICIAL LANGUAGES."

We have received a letter from Dr. Sydney Whitaker, of Waterloo, Liverpool, Vice-President of the T.E.K.A., an association of Esperantists, of which an account was given in the BRITISH MEDICAL JOURNAL of December 5th, 1908, p. 1687. Dr. Whitaker charges us with making "misleading statements" about Esperanto. One of these would appear to be that Esperanto is not a living language. We are assured that it has been a living tongue for several years, "spoken whenever and wherever Esperantists meet." If this criterion be accepted, it might be argued, with much greater force, that "Yiddish," "thieves' Greek," and the many varieties of argot in different countries, are living tongues. Dr. Whitaker informs us that there is no "natural language." The BRITISH MEDICAL JOURNAL is scarcely the place for a discussion on the origin of language, a problem as to which the French Institute many years ago had to decline to receive communications. But surely there is a difference between a language learnt at one's mother's knee, spoken by a whole people whose legends, poetry, achievements and aspirations are written in it, and an artefact product formed in a way that suggests that its begetter had, as Armado's page says in *Lore's Labour's Lost*, "been at a great feast of languages and stolen the scraps." Even if we allow Esperanto to be "living," in the same sense as the man made by Frankenstein was living, the question remains, Will it live? If we may say so, with all respect, we should judge that Dr. Whitaker has not given much attention to the study of the history of languages, or he would not be so perplexed as he appears to be by our statement that if Esperanto is to live it must, as it is spoken by people of different nationalities, suffer changes which will in the course of time make them unable to understand each other. Dr. Whitaker finds our statement that nationality modifies language neither grammatical nor lucid. On the point of grammar he must excuse us if we do not accept him as an authority. As regards lucidity, will he contend that an acquired language is quite the same thing in the mouths of men of different nations? This very day we overheard an educated Englishman ask a Swiss waiter the extraordinary question how "maudeagraw" came by its name. The foreigner was completely non-plussed, till philanthropy led us to whisper to him that the interpretation of the mysterious word was "Mardi gras." Do Italians, Frenchmen, and Germans all speak English with the same accent or with the same turn of phrase? If even the English-speaking peoples differ in their use of a common language which they have learnt in the natural way, it is surely not a dark saying that different races speaking an artificial jargon will impress upon it something of their own linguistic character. We may remind Dr. Whitaker of the Prioress, of whom Chaucer says:

And Frenssh she spak ful faire and fetisly
After the scole of Stratford-atte-Bowe.
For Frenssh of Parys was to hire unknowe.

We venture to foretell that in a few years the Esperanto of Paris will be almost as unknown to Dr. Whitaker. This prediction is not made at random, for a French writer, M. Remy de Gourmont, not long ago related the experience of a foreigner who went to Paris fondly thinking that Esperanto would smooth away all difficulties of language. He found that no one understood him. This victim of misplaced confidence, speaking perhaps in his wrath, describes Esperanto as a mosaic of vocables taken from various European tongues, but carefully deformed by the removal either of the first syllable or the last. The result is often misunderstanding of a deplorable kind. Now, he says that he knows a little French, and wishes

to know what mental aberration has led Esperantists to use *viol* (rape) to denote a violet. We have not space for his account of his misadventures with Esperanto, but we may quote his conclusion. Having left home, he says, with a large stock of Esperanto, he will return with a little knowledge of French. This he considers an immense gain. French has given him the key to a new world. We congratulate him, for Esperanto scarcely serves to give him the key to a room in a hotel. That is the whole case in a nutshell.

SPIRITUAL HEALING BEFORE THE FRENCH LAW.

THE French Supreme Court of Appeal decided eight years ago that persons not possessing a regular medical diploma who professed to cure disease by "magnetic passes" came under the provisions of the Law of November 30th, 1892, against unqualified practice. This decision was understood to apply to all forms of treatment by what may be called non-medical methods. A recent decision of the *Chambre Criminelle* of the Court of Appeal would seem, however, to imply that this is not the case. An appeal was lodged against a judgement acquitting a youth who, as may be gathered from the text of the decision which is published in the *Semaine Médicale*, practised what would in this country be called spiritual healing. The decision sets forth that it appears from the evidence in the case that X., aged 16 years, when he received or visited sick persons who sought his aid for the relief or cure of their ailments, confined himself, invariably and whatever the nature of the disease, to placing one of his hands on the seat of pain, addressing a mental invocation to a spirit which he believed himself to have the power of moving to favourable intervention; that he had never in any circumstances ordered any remedy or medicament of any kind, given any prescription, or direction to the patients; that his acts had nothing in common with medical treatment, and were based wholly upon his belief in supernatural help without the employment of any therapeutic procedure; and that in these circumstances, which had been fully proved, the decision appealed against was right in view of the fact that X. had not committed the offence of illegal practice of medicine as defined in Article 16 of the Law of 1892, and forbidden by Article 18 of the same law. It follows that there was no violation of the law. On these grounds the appeal was rejected. The French are the most logical of people, and they are justly proud of their system of law in which everything is codified, and the provisions are laid out with the symmetry of a Dutch garden, in a manner so different from the chaos of cases and judgements and Acts of Parliament in which the dispensers of justice in this country have to grope their way. The case we have quoted, however, seems to show that even the French law is sometimes in contradiction with itself, unless it be held that "magnetic passes" are mere tricks, while the invocation of healing spirits is an appeal to something believed to be real. In that case all the magnetisers have to do to put themselves in order is to add incantations to their "passes." The problem is a knotty one, for according to the French law as expounded by our contemporary, either spiritual healing is a vain thing, and therefore comes within its provisions as a fraud, or it has some active effect, and then it comes under them as a form of quackery. This dilemma, however, is of too wide a compass to catch within its horns any but those who deny the possibility of any spiritual intervention in human affairs. An enactment interpreted in this rigid spirit

would treat prayer to the Deity for a person afflicted with a disease as a violation of the law against the illegal practice of medicine. This would be absurd, for it would penalize prayer for the sick and punish a person for believing in a spiritual power.

PUBLIC OR PRIVATE PHILANTHROPY.

WHILE philanthropic institutions abound on every hand and workers are always forthcoming to serve on committees, the study of the wide subject of philanthropy in relation to the State is probably but little regarded in the desire to push forward the claims of each particular scheme to which its supporters have committed themselves. The late Mr. Kirkman Gray left behind him a series of papers which his widow, assisted by Miss B. L. Hutchins, have now issued in a volume¹ which is not only interesting as giving a clear account of the lines of thought that have slowly developed as experience has increased, but contains the carefully thought-out conclusions of a student of the subject. These conclusions are worthy of careful consideration by all who may be occupied in the same field of labour. In the first part of the book the transition in thought is traced by which private philanthropy has gradually passed, and is still passing, into the hands of public bodies. The general thesis is laid down for discussion that widespread want resulting from broad and general causes cannot be adequately provided for by private philanthropy, and that it is the business of the community to assist its weaker constituents, and at the same time to control them. But there is no consistent doctrine to determine the relation of the State or community to the weaker classes of society, and for lack of it there has at all times been a wastage of power and a partial failure in result. The history of the advance of public recognition of public duties shows only too plainly that the stimulus of the agitator has been needed before effective action has been taken. The reform of the prison system, of the Poor Law, of sanitation, education, and a host of other movements for the improvement of the conditions of life for the poorer classes, were all started and stimulated by the action of agitators, such as Mrs. Fry, Mr. Chadwick, and many others, the support of the general philanthropist following afterwards, and leading by slow degrees to official action and control. The second part of the book is devoted to the discussion of the means by which the intervention of the State can best bring about the necessary control, and to what extent it can best be left to co-operate with private philanthropy. Among many questions thus considered there is probably none that commands more serious thought than that relating to the prevention of crime by juvenile offenders. It will doubtless surprise the reader to learn that the proportion of criminals convicted in this country between the ages of 12 and 16 stands at a higher figure than for the age-period from 21 to 30. The Prisoners' Aid Society does much to reclaim, but further co-operation between private workers and public officials is needed to cope with the circumstances which lead to such an appalling amount of juvenile depravity. In relation to the hospital system as at present prevailing, the gradual multiplication of institutions both for treatment and for isolation which are under public official control appears already to have reached the proportion of two-thirds of the whole number of public hospitals, and only one-third still remain under the control of committees responsible only to their own subscribers. This part of the subject does not appear to have been very fully con-

¹ *Philanthropy and the State, or Social Politics*. By Kirkman B. Gray. Edited by Eleanor Kirkman Gray and B. L. Hutchins. London: P. S. King and Son. 1908. (Demy 8vo, pp. 350. 7s. 6d.)

sidered by the writer, and may be regarded, with some other papers contained in the volume, as a fragment only, the completion of which was prevented by his early death. It is, however, well worthy of careful study as indicating some of the lines which future developments are likely to follow.

RESEARCH DEFENCE SOCIETY.

THE letter from Mr. Stephen Paget, which is published at p. 304, shows the progress made by the Research Defence Society within a year of its foundation. Beginning this time last year with 7 members, it has now more than 2,000, of whom 230 are ladies. A branch has just been formed at Dublin: 700 persons were present at the inaugural meeting. The branch has already 400 members. Branches have also been formed at York and Birmingham, and others are in course of formation at Bournemouth, Brighton, Cambridge, Edinburgh, Hull, Leeds, Liverpool, Manchester, Norwich, Oxford, Shrewsbury, and Torquay. The method in which the society conducts its campaign is fully described by Mr. Paget; his letter will, we hope, be read by every one under whose eyes the JOURNAL comes. We feel strongly that his disinterested efforts in a cause the advocacy of which necessarily entails upon him a good deal of unpleasantness from those opposed to vivisection entitle him to the gratitude of all who have at heart the advancement of the art of healing. We congratulate him and his fellow workers on what they have already done for the diffusion of a knowledge of the truth about the methods of biological experiment and the confutation of calumnies, and we heartily wish them increasing success in their most useful and truly philanthropic undertaking.

INTESTINAL PSEUDO-PARASITES.

DR. MALCOLM ALLEN ROYAL¹ has made a study of the mistakes which may arise in microscopic examinations of the faeces through confusing various kinds of vegetable material with animal parasites. Banana fibres are sometimes mistaken for tapeworms, and two cases of this nature have been cleared up in the author's laboratory. One was a child, aged 2 years, who was said to become more or less restless just before passing these spurious worms; the other was a man, aged 38, suffering from anaemia of obscure origin; his stools had been examined and material resembling tapeworms had been occasionally found. Upon further correspondence with the attending physicians, the connexion of these appearances with the ingestion of bananas became fairly well established. Many cases are on record where the cells of oranges or lemons have been mistaken for trematodes. Dr. Royal records the case of a man of middle age, apparently in good health, who noticed on several occasions a peculiar appearance in his faeces, and brought specimens to his doctor, who examined them microscopically. The doctor was puzzled at first as to their nature, but on questioning the patient found that these supposed worms occurred in the faeces only after eating oranges, and that oranges disagreed with him. The doctor's suspicion that the material in question really consisted of orange cells was confirmed by appeal to a botanist. Celery fibres may be mistaken for *Ascaris mystax*, *Oxyuris vermicularis*, *Uncinaria americana*, *Trichocephalus trichiurus*, or *Dipylidium caninum*. On several occasions Dr. Royal has found these fibres in specimens of children's faeces which have been

brought to him on the supposition that the excreta contained parasitic worms. The vegetable character of the material was at once proved on testing it for cellulose, and inquiry elicited the fact that the passage of the faeces had been preceded by an attack of indigestion due to eating celery. Fragments of onion, according to the author, may be mistaken for *Ascaris lumbricoides*, *Anchylostomum duodenale*, or *Ascaris mystax*. Sauerkraut, he finds, might be mistaken for the undeveloped *Ascaris lumbricoides*, *Ascaris mystax*, or *Uncinaria americana*. Portions of dates, oatmeal, thread, rhubarb, and pineapple are also liable to lead to an erroneous diagnosis of various parasitic worms. An interesting feature of Dr. Royal's work is that in the case of all the above-mentioned vegetable materials he has demonstrated the resemblance to animal parasites by experiment upon himself. "As experimental work, I ingested large quantities of the different fruits and vegetables, making the diet for the day consist principally of one article. At various intervals following the ingestion of the different substances, examinations of the stools were made, and especially after the end of twenty-four hours, this being the time generally required for the food to pass the length of the intestinal tract." As a standard for comparison with the material found in the faeces, teased fragments of the various vegetables, after maceration in 5 per cent. potassium hydrate, were used. Dr. Royal supplements his article with an interesting set of drawings showing the resemblances between the true and the pseudo-parasites.

A RADIUM INSTITUTE.

THE announcement which appeared in the newspapers on Thursday as to the foundation of a Radium Institute was incorrect in several particulars. There is no question of a Royal Charter being granted. The institute will bear the name of "The Radium Institute." The King has taken the keenest personal interest in the foundation of such an institute, and it is through his instrumentality, aided by the liberality of Sir Ernest Cassel and Lord Iveagh, that the scheme is now about to be carried into effect. A committee has been formed, of which the chairman is Sir Frederick Treves, Bart., G.C.V.O., C.B. The members will include one named by Sir Ernest Cassel, one named by Lord Iveagh, Sir William Ramsay, K.C.B., the Hon. R. J. Strutt, Professor Sir J. J. Thomson of Cambridge, Sir Lauder Brunton, Bart., and Sir Malcolm Morris, K.C.V.O. We understand that a site has been secured, but it is not expected that the institute will be ready for work for some months. The institute will have no connexion with the Imperial Cancer Research Fund.

THE King has been pleased to appoint Mr. George Andreas Berry, M.B., C.M. Edin., F.R.C.S. Edin., to be Honorary Surgeon Oculist to His Majesty in Scotland, in the room of the late Dr. Argyll Robertson.

ON the occasion of the publication on January 1st of the first number of the twenty-fifth volume of the *International Centralblatt für Laryngologie, Rhinologie, und Otologie*, Sir Felix Semon, its founder and editor, received from laryngologists all over the world most gratifying expressions of their appreciation of the great services rendered to the study of the speciality by the foundation of that periodical and by the manner in which it has been conducted.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

HOSPITALS AND THE EDUCATION AUTHORITIES.

AFTER a full discussion, the joint committee of the Manchester and Salford Divisions has declared itself strongly opposed to any arrangement by which public hospitals would undertake to treat school children in return for a subsidy from the education authorities. The committee entirely disagreed with the system which is now being tried in Sheffield. In that city the education authorities have entered into an arrangement by which, in return for every guinea subscribed by the authority to a hospital, six recommendation letters shall be received, which the authority can distribute to children needing treatment whose parents are unable to pay ordinary fees. The joint committee considers that even if a guarantee be given that full inquiry will be made as to the circumstances of the parents, and that only those who are unable to pay will be sent to the hospitals, the objections against public authorities dumping their patients into charitable institutions still remain. It is unfair to the subscribers, and beyond a doubt will very soon lessen the amount of charitable donations to hospitals; in fact, it would be just as reasonable if workhouse hospitals were to ask for public donations. It is equally unfair to the honorary staffs of the hospitals, who, in many cases, have already more work than they can well do, and it would only be mere justice that those who do the work the State requires should receive the pay. In its last annual report, the Medico-Political Committee, in reply to a request for advice from the Ulster Branch of the British Medical Association on the matter of treatment in hospitals having honorary staffs, recommended that the services of the medical profession should not be given gratuitously to patients who are maintained by public funds. The Annual Representative Meeting was entirely in agreement with this and passed a special resolution to this effect. The question is sure to be raised in Manchester before long, for already some of the hospitals are finding that their resources are being taxed by the large number of school children crowding to them, whose parents have been urged by the authorities to provide medical or surgical treatment; some of the hospitals are in such a critical financial condition that it would probably need some firmness on the part of the medical staffs to resist a scheme like that of Sheffield.

THE ROYAL INFIRMARY AND MEDICAL WOMEN.

Last week the Board of Management of the Royal Infirmary received a deputation from the Federation of University Women in Manchester and the Association of Manchester Medical Women, together with a representative of the medical women students in Manchester. The deputation presented resolutions from the societies mentioned urging the claims of medical women as candidates for resident appointments at the new infirmary. The Chairman of the Board assured the deputations that the board was in full sympathy with their request. The medical board also favoured the idea of throwing open to women the resident posts at the infirmary, and had twice recommended the board to do so. He regretted, however, that, owing to lack of accommodation in the new building, it was at present impossible for the board to consider applications from women candidates for resident posts. It was a pity that the application had not been made five years ago, when the plans for the new building were under consideration. In a letter to the *Manchester Guardian* the deputation replies that such a request would have been unreasonable at that time considering the limited accommodation in the old building, and it never doubted that the building of the new infirmary would solve the problem of accommodation. The letter continues: "It is unthinkable that the board which has carried out this great scheme could not with the help of the able superintendent reorganize the present accommodation in such a way that quarters may be found if necessary for a woman resident, and the fear is expressed that exclusion from the resident infirmary posts in Manchester may drive the most promising women students elsewhere."

INFIRMARY ARRANGEMENTS.

Arrangements have now been made for the treatment of accidents and casualties at the central branch of the infirmary which is still kept at the old buildings in Piccadilly, and which will be worked in conjunction with the new infirmary. The casualty and accident department at the new infirmary is, of course, open day and night, but the central branch in Piccadilly is for the present only to be open from 9 a.m. to 6.30 p.m. every week-day for minor accidents and emergencies, and an adequate staff of doctors and nurses will be kept there during these hours. It has also been arranged that out-patients who reside at such a distance from the new infirmary as to make it difficult for them to attend there, may be seen at the Piccadilly branch at 9 a.m. All the arrangements are of a provisional nature and may be modified from time to time as occasion requires.

LIVERPOOL.

SUGGESTED MUNICIPAL ACTION FOR DEALING WITH TUBERCULOSIS.

COUNCILLOR A. SHELMEIRINE, who has devoted many years to problems of public health and especially to the question of tuberculosis, has presented to the health committee his report as delegate of the committee to the International Congress of Tuberculosis at Washington. He recommends: (1) The establishment of a municipal dispensary, or arrangements with the existing dispensaries, in the poorer quarters of the city, where those persons afflicted with tuberculosis might attend at stated periods to be examined, receive advice and, if necessary, treatment. (2) The provision by the municipality of beds in an open-air hospital or sanatorium for the treatment of early cases of the disease. At present, he says, a man with consumption has no opportunity for treatment unless he has means at his disposal, and his only alternative is to find refuge in the Poor-law infirmaries. (3) The provision of an institution for the isolation of those advanced dangerous cases which could not be properly isolated and treated at home. The advanced case of consumption was the most dangerous form of the disease to the community, as it was principally through such cases that the healthy members of the family were infected. (4) As far as possible, healthy children should be isolated from those suffering from tuberculosis, as they were most susceptible to attack. (5) The provision of a pure milk supply was of the highest importance, and until tuberculosis could be eradicated from dairy cows the number of sterilized milk depots should be increased, as there was no doubt that they had already saved thousands of infant lives. The measures at present in operation in Liverpool were, as far as they went, as perfect as possible for the suppression of tuberculosis, but they were insufficient when it was considered that there were 8,000 or 9,000 people in the city suffering from the disease, and that over 2,000 lives are annually lost in Liverpool by its ravages. Something of a more far-reaching nature should be attempted by an important municipality like that of Liverpool. Dr. H. H. Clarke, chairman of the Medical Board of the Hospital for Consumption and Diseases of the Chest, has written to the press pointing out that Mr. Shelmeirine has not recognized the fact that what he now recommends has for the most part been carried out in practice for many years by that hospital, which has a branch sanatorium with 40 beds in Delamere Forest, has 30 beds in the hospital in Mount Pleasant, has a large out-patient dispensary and a laboratory; it has further co-operated with the health committee on the lines which Mr. Shelmeirine recommends, and has an arrangement with the Victoria Nursing Association for visiting patients in their own homes.

THE POOR-LAW SANATORIUM AT HESWALL.

The annual report of West Derby and Toxteth Park Joint Hospital at Heswall, drawn up by the Clerk to the Committee (Mr. H. P. Cleaver), has just been issued. From this it appears that the weekly cost per head was: In maintenance, 14s. 6d.; building repairs, furniture, etc., 10s. 0d.; and other charges, £1 1s. 8d. With regard to the cost and the results obtained, Mr. Cleaver draws attention to the following points:

Cost of Maintenance.—With regard to this apparently large item, it should be remembered that sanatorium patients cannot be treated without very good and plentiful food; also the quantity of clothing required is in excess of an ordinary hospital. Further, in necessitous cases, flannel underclothing is given to patients on their discharge. The greatest handicap under this heading is the small number of beds, as it has been proved beyond any doubt that it is always more expensive proportionately to keep up a small establishment than a large one. Again, the fact must not be lost sight of that a proportion of the patients treated in the hospital have ceased to be a burden upon the rates through recovery, whereas probably all of them would still have been in and out of hospital had the sanatorium not existed.

Result of Treatment.—The lay mind is so expectant as to look for a "cure" in every case treated, whereas in many cases it is a subject for satisfaction when the disease is "arrested" or "quiescent," so as to enable the patient to follow some employment. It is difficult to keep in touch with every patient after leaving, but some old patients had visited the hospital who owed their present good health to their treatment, and who would willingly present themselves to the committee should they wish it. They are all working, and some have been discharged for a considerable length of time. Nine former patients visited the matron at Christmas, and all were in good condition with one exception and earning their own living. Another point that should be emphasized is that 75 per cent. of the cases treated last year were discharged free from the tubercle bacillus, so that they have ceased to be dangerous to the general public. The standard of classification of patients on discharge is a very high one, the patient being entered as "disease arrested" if there seemed to be the slightest doubt of his relapsing in even a small degree. Without prejudice, and for a fact, I know that the officials at the hospital are more cautious in this way than is the general rule. This makes a fresh difference in the appearance of the statistics. Boards of guardians all over this country are beginning to realize the fact that the West Derby, Liverpool, and Toxteth guardians, in being the pioneers in this movement, have taken a most essential step towards the public welfare, and one which will soon become universal. I believe that the Bradford guardians, the second in the field, are now enlarging their sanatorium.

BIRMINGHAM.

PLAYING FIELDS FOR BIRMINGHAM.

UNDER the auspices of the Birmingham and District Housing Reform and Open Spaces Association, a public meeting was held at the Council House recently to consider a scheme for acquiring 250 acres of land from the Birmingham, Tame, and Rea District Drainage Board at Castle Bromwich for the purpose of providing suitable playing fields. It was estimated that the land would be self-supporting, as it would be utilized by the numerous cricket and football clubs in the neighbourhood. A resolution to support the association in acquiring the land was carried unanimously.

MEDICAL INSPECTION OF SCHOOL CHILDREN.

The Medical Officer of Health for West Bromwich has just issued his first annual report on the medical examination of the children attending the elementary schools in the borough. Dr. H. Manley is not only the medical officer of health but also the school medical officer, and he has examined upwards of 3,300 children since his appointment in March, 1908. He has adopted a system with regard to the examinations by which it will be possible to trace every child from its birth to the end of its school life, and to establish a set of complete statistics of considerable local value. He divides the parents of children attending elementary schools into four distinct classes:

1. Those who really take an interest in their children, and who could, if they chose, send their children to private schools, but are fully sensible of the excellent teaching provided by the State.
2. Parents who are equally interested in their children, but have not the pecuniary means to carry out all that they would wish.
3. Parents who are in the position of Class I, but who are quite indifferent as to the cleanliness or welfare of the child.
4. The idle, dissolute class, where the home is dirty, the parents often drunken, and where the child reflects in clothing, in boots, in vermin, and in health the home environment.

The boys, of whom only one-third had reached the sixth standard, averaged 54.8 in. in height and 73.6 lb. in weight. The girls averaged in height rather more, being 55.7 in., and in weight 72.8 lb. In the matter of boots and clothing, while both sexes were gravely in need of boots, the

boys especially, there were 42 boys and 12 girls insufficiently clad. Dr. Manley comments severely on the verminous condition of the girls. Inquiry was made as to the care of the teeth, and in most cases it was found that a toothbrush was never used, yet the condition of the teeth was much better than might have been expected. The condition of the eyes and eyesight was only tested by the master or mistress in many schools, but sooner or later a specialist must be appointed. A certain number of children were found to be backward and defective, and required more detailed and personal attention than could be given in the present condition of an ordinary school. For such children it might be possible some day to provide special schools. The chief factors which singly or in combination were found to be the cause of retardation in school progress were:

1. Mental defects, generally hereditary, but in some rare cases the result of illness or shock. This class should as far as possible be sent to special schools.
2. Physical defects.
3. Frequent and prolonged illnesses which have prevented the child from regular attendance at school.
4. Constant migration from town to town, or even from school to school.
5. Bad environment, including bad homes, drunken parents, criminal surroundings, neglect, and indifference.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

UNIVERSITY OF EDINBURGH.—HISTORY OF MEDICINE.

THE second of the course of eight lectures on Medicine among the Ancient Egyptians, Greeks, and Romans was given by Dr. John D. Comrie on Wednesday, January 20th. The lecture consisted mainly of a consideration of the Ebers and Berlin medical papyri, followed by a demonstration of lantern slides illustrative of Egyptian life, Egyptian pathology, and Egyptian surgery.

ROYAL INFIRMARY, GLASGOW.

THE annual meeting of the contributors was this year of special importance. The annual report submitted showed that, despite the reconstruction, the work of the hospital had not been impeded or materially diminished. While the average number of resident patients was 591, against 593 in the previous year, the outdoor department treated over 5,000 more patients than in 1907. The average cost of each bed, fully occupied, was somewhat higher than in the previous year—£70 9s. 11d., against £69 5s. 6½d. in 1907. The honorary treasurer's report showed that the total ordinary revenue was £30,308, while the total ordinary expenditure was £42,969, leaving a deficiency of £12,661, but the extraordinary revenue, £43,954, was very high, so that, after meeting the deficit of the ordinary income, the sum of £31,293 was carried to the credit of the stock account—the largest amount on record. The reconstruction had made great progress during 1908, and it was expected that the laundry power house, extension of nurses' home, and admission building would be ready for occupation in the spring, and that the north or surgical block would be ready for patients before the autumn. Immediately on completion of the north block the managers proposed to proceed with the erection of other portions of the new building. The present building scheme had nearly exhausted the special fund of £128,000 collected in 1904. The first (1897) fund was earmarked for reconstructing the front or medical block. As the present time was not very suitable for collecting more money, the managers asked the Court of Contributors for authority to transfer £150,000 from the Accumulated Stock Fund and use it for building purposes. The report alluded to the agreement come to by the boards of the infirmary and St. Mungo's College as to the best means of securing the continuance of clinical teaching in the Royal Infirmary and the subsequent conferences which took place between representatives of these boards and the University Court.

The Lord Provost moved the adoption of the report; the motion was seconded by Principal Sir Donald MacAlister,

who stated that in his opinion the proposals made at the conferences with the University Court were eminently reasonable and practicable, though details were still under consideration. He had no hesitation in anticipating that a satisfactory arrangement would be carried out; in that case better accommodation for teaching women students would be made and the opportunities for all other medical students would be so amplified that Glasgow as a clinical centre would compare well with any other.

In moving a special resolution to authorize the transfer of £150,000 to the building account, Mr. J. D. Hedderwick said that, though the formal notice of the motion had been very short, still the subject had been mentioned in every annual report since 1896. The citizens had responded handsomely to the appeals made in 1897 and 1904. On the first occasion they were asked to subscribe to the reconstruction of the front block as a memorial of Queen Victoria's Diamond Jubilee. Of the £100,000 asked, £80,000 had been obtained, which, with interest, was now £98,000. It was earmarked for this special purpose. The appeal in 1904 produced £128,000, which was raised by interest to £138,000, but this sum had now almost all been paid away. The total cost of reconstruction was estimated at £500,000. The stock account amounted to £295,976; if the transfer of £150,000 was authorized, this, with the money collected, would make £386,000 of the total £500,000 required. The motion was seconded by Mr. J. Glen, and evidently met with the full approval of those present, as an amendment moved by Dr. Charles Workman that the matter be referred back to the managers for further consideration was not seconded.

JUBILEE INSTITUTE FOR NURSES.

The report of the Council of the Scottish Branch of Queen Victoria's Jubilee Institute for Nurses for last year showed that there are now 303 nurses on the roll. An average of eleven new posts yearly had been created in the last six years. The Council had acquired and furnished an adjoining flat, and arranged that two more Queen's nurses should be trained every half-year. This flat had been purchased out of the funds bequeathed to the institute by the late honorary secretary, Miss Guthrie Wright. To provide the additional income to cover present expenditure and to meet the training of the four extra nurses the public were appealed to. Thirty-five nurses had completed their course of six months' district training during the year. Two of them were given the special training necessary to qualify for the examination of the Central Midwives Board, which they had passed. During the year the Scottish Council was responsible for the maintenance of thirty-seven Queen's nurses and probationers. Thirty-two nurses whose training had been completed during the year had been permanently engaged by local committees. The number of affiliated branches in Scotland was now 199. A Queen's nurse from the home had given daily attendance at the special school for cripple and mentally deficient children. Sir Henry Littlejohn claimed that the institute should rank along with the municipal and other public bodies as a large contributing factor in the reduction of the death-rate; he contrasted the state of things prevailing in the homes of the poor before the introduction of Queen's nurses with that of the present day, and spoke in the highest terms of the quiet, unobtrusive work of the nurses in their attendance on both acute and chronic disease.

SELKIRK MEDICAL OFFICERSHIP.

The Town Council of Selkirk has had considerable difficulty in finding a successor to Dr. John Muir, who resigned the medical officership of the burgh some time ago. The position was offered to Dr. Somerville, the medical officer of health for Galashiels, but he did not see his way to accept it. At a recent meeting of the council it was suggested that the vacant appointment should be advertised, but at a salary considerably higher than that paid to Dr. Muir. Another proposal was that Dr. Oliver Newton, medical officer for Roxburghshire, should be appointed, with Dr Muir as assistant. Neither plan was approved. In order to get out of the difficulty, the council has now decided to ask Dr. Muir to continue in office, and it has been agreed to offer him a considerable increase in his salary.

Ireland.

[FROM OUR SPECIAL CORRESPONDENT.]

ULSTER MEDICAL SOCIETY.

ON Thursday evening, January 21st, Mr. Kirk, the President of the Ulster Medical Society, entertained the Fellows and Members to a most enjoyable smoking concert in the Medical Institute, Belfast. About 120 were present. Mr. and Mrs. Kirk received the guests in the library, and subsequently the concert was held in the large hall of the institute. Several members and friends sang, and some short and witty speeches were enjoyed. Reference was made to the conferring of the honorary Fellowship of the society on Sir William Whitla, and Sir William suitably replied.

Special Correspondence.

MUNICH.

New Chief Medical Officer of Health.

AN important change is about to take place in the post of the highest Bavarian medical officer. Geheimrat Grashey, Medicinalreferent im Ministerium des Innern, retires on February 1st, and will be succeeded by Professor Dieudonné. This appointment has been made in accordance with the special wish of the new Minister of the Interior, v. Brettreich, and it may be regarded as the commencement of a new era in the administration of medical affairs, and as foreshadowing hygienic reforms. Professor Dieudonné, until now an army medical officer, is well known as a hygienist, especially as a bacteriologist. From 1893 to 1898 he was attached to the Kaiserliche Gesundheitsamt in Berlin. In 1897 he was a member of the imperial commission under Koch for the investigation of the plague in India. From 1898 to 1904 he lectured at the University of Würzburg, being at the same time head of the military bacteriological investigation laboratory. Since 1904 he has held a similar position in Munich. His widest-known work is *Immunität, Schutzimpfung und Serumtherapie*, an admirable survey of modern progress in these subjects. Personally he is highly esteemed and liked, and is regarded by the medical profession as certain to be the right man in the right place.

Correspondence.

RESEARCH DEFENCE SOCIETY.

SIR,—Wednesday in this week (January 27th) is the first anniversary of the founding of the Research Defence Society. The committee, therefore, wish me to send you a short statement of the work of the past year.

The society will celebrate its birthday by the inaugural meeting of the Dublin Branch. This meeting will be held in the theatre of the Royal Dublin Society. More than 180 persons, beside members of the medical profession, have expressed their intention of joining the Dublin Branch Society. Among them are the Archbishop of Dublin, Lord Iveagh, Lord and Lady Pembroke, Lord Ashbourne, Lord Monck, the Bishop of Clogher, the Bishop of Tuam, the Deans of St. Patrick and of Christ Church, Dublin, the Provost and Vice-Provost of Trinity College, Dublin, and Sir Neville Lyttelton. By the inauguration of this branch, the Research Defence Society, which had but 7 members this time last year, will now have more than 2,000, of whom 230 are ladies.

The society has lost by death 10 members: Professor Ayrton, Sir John Banks, Mr. Harold Barnard, Dr. C. E. Beever, Dr. J. G. Glover, Mr. Arthur Lister, Lord Polimore, Mrs. Roget, the Earl of Rosse, and Sir Thomas Stevenson.

Since the last report, which I sent to you in May of last

year, the following have consented to be Vice-Presidents of the society:

Sir William Abney.	The Duchess of Montrose.
Mrs. Garrett Anderson.	Mr. Eden Phillpotts.
Lord Barrett Ball.	Lady Priestley.
Lord Barrymore.	The Bishop of Bangor.
Lady Bliss.	Mrs. Romanes.
Lady Buckley.	The Marchioness of Sligo.
Lady Burdon-Sanderson.	Lord Stalbridge.
The Dean of Chester.	Lady Stanley of Alderley.
Lady Cromer.	Lady Sutton.
Lady Foster.	Sir Reginald Talbot.
The Earl of Glasgow.	Mr. A. G. Vernon-Harcourt.
Sir Samuel Hoare.	Bishop Welldon.
Lord Lamington.	The Duke of Wellington.
Sir Frank Lascelles.	Mrs. Robert Peel Wetherhead.
Lord Malmesbury.	The Bishop of Winchester.
The Duke of Montrose.	

Rules for the society, and for the branch societies, have been approved by the Committee, and will be submitted in due course to a general meeting of the society.

Branch societies have already been formed, or are in course of formation, in Birmingham, Bournemouth, Brighton, Cambridge (University Branch), Dublin, Edinburgh, Hull, Leeds, Liverpool, Manchester, Norwich, Oxford, Shrewsbury, Torquay (Devon Branch), and York. Several of these branches have already more than one hundred members.

The progress of the society has been watched with great interest in America, by many well-known representatives of science and medicine; and steps have been taken for the defence of research in the United States.

The society has issued the following pamphlets:

1. Letter from the President, announcing the formation of the Society.
2. Report of the Inaugural Meeting.
3. Experiments on Animals during 1907 in Great Britain and Ireland.
4. Some Facts as to the Administration of the Act.
5. The Value of Antitoxin in the Treatment of Diphtheria.
6. Evidence of Sir Frederick Treves.
7. Yellow Fever and Malaria.
8. Have Experiments on Animals advanced Therapeutics?
9. The Extinction of Malta Fever.
10. Evidence of Lord Justice Fletcher Moulton before the Royal Commission, July, 1907.
11. The Work of the Research Defence Society.

A further series of pamphlets is in course of preparation, including:

1. The recent correspondence in the *Times*.
2. An account of the use of a serum treatment in cases of epidemic cerebro-spinal meningitis.
3. An account of the anaesthetics used in experiments on animals.
4. Answers to some statements commonly made by the opponents of all experiments on animals.
5. A reprint of Dr. Bushford's article on the Advance in the Knowledge of Cancer (*Nature*, December 31st, 1903).

A great many bound sets of the pamphlets already issued have been sent to the chief public free libraries in London and in other towns, and to many other libraries, institutes, and clubs. Very many have also been sent in answer to personal applications. These bound pamphlets may be procured through any bookseller.

Representatives of the Research Defence Society have spoken at a large number of meetings or debates in London or in other towns. On other occasions the society has sent literature for the use of speakers in debate. The society is always willing to send a representative to a debate arranged by any literary society, club, or debating society, or to any public meeting, with this exception, that it does not propose to accept "challenges" from the antivivisection societies or to arrange with them the terms of a debate.

A collection of lantern slides has been prepared, with a descriptive catalogue, for the use of anybody who wishes to give a lecture on some of the discoveries that have been made by the help of experiments on animals.—I am, etc.,

STEPHEN PAGET,

Honorary Secretary Research Defence Society.

70, Harley Street, W., Jan. 25th.

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

SIR,—The suggestions which appeared in the *JOURNAL* of January 9th in the letter of Dr. Harvey Hilliard, advocating the existing Poor Law and its institutions as the

method and means by which defective children in the elementary schools of the country should be dealt with, will not, I hope, be taken too seriously by the medical profession, and still less form the basis of any recommendation to the Education Department and county council authorities by the British Medical Association as a whole. The principle laid down by Dr. Hilliard in his letter is so thoroughly bad and out of date with modern thought and the times that I do not propose to follow him in detail to show how impracticable and impossible are his suggestions from a Poor-law point of view, but I assert that it would be easy for officials engaged in the practical administration of it—as apart from the knowledge which guardians possess, and who only know one side of the work—to show that, besides its impossibility, his scheme, if adopted, would not at any rate mean economy, but rather an enormous increase in national and local burdens.

It is useless for Dr. Hilliard and those who agree with him to argue upon supposed alterations expected by the promised report of the Poor Law Commission; that report is not yet before us, and, whatever its decisions might be, it would have to be followed by legislation, and could not be applied to this question. The reform of the Poor Law is needed, but it will still have to be Poor Law, of a more modern, humane, and discriminatory character; but it will not, and should not, be applicable in any way to the children of the nation now outside the Poor Law.

It is more than probable, and I think highly necessary, that any alteration in the Poor Law will be in the direction of divorcing the Poor-law children from their present care and giving to them the same chance in life that falls to the lot of other children more happily placed, and whom we rightly regard in common with our other children as the future assets of the nation. It is quite certain also that, assuming it were possible—and it is a very large assumption—to deal with all these defective cases through the agency of the Poor Law and its kindred institutions, the necessity of greatly increasing the staff and equipment of the various infirmaries would entail such enormous expenditure, out of all proportion to any benefits and results obtained, as to greatly exceed what Dr. Hilliard and we all agree in lamenting—namely, the present high taxation for Poor-law purposes.

We all know that under the present Poor-law system these "children of the State" cost the ratepayers on an average £30 *per annum* for maintenance purposes alone, not counting the thousands and thousands of pounds of ratepayers' money spent in capital construction and in establishment charges, and still less counting the extra cost of the defects from which they suffer, and yet Dr. Hilliard would have us believe that it would be more economical to draft our other defective children suffering from ringworm, ophthalmia, etc., into our Metropolitan Asylums Board schools and homes, and our adenoïd and other children into our Poor-law infirmaries and Poor-law schools with their blighting and demoralizing influence upon the children, rather than to have these children treated in the school clinics with other neighbouring medical agencies, part and parcel of a continuity of educational work, in the atmosphere of their homes, friends and companions, and with the air of freedom, decision, and initiative, which alone can build up self-reliant and resourceful characters. If any one doubts the demoralizing effects of our Poor-law system upon "the children of the State," let them read the letter of Lord Lytton and Mrs. Barnett in the *Times* of January 8th, and also the recent report upon the educational work of the Poor Law in the certified schools of England and Wales by the Board of Education, which letter and report are unanimously condemnatory.

Dr. Hilliard will admit that whilst all this treatment for defects may be going on under his proposed Poor-law system, the children must be educated during the period of detention. It is shown by the clearest evidence that under Poor-law auspices these children are a year behind the standard of ordinary children, and that during the best time of their growing lives, when vital impressions are most easily received, as the report says:

Rows and rows of fat, clean, well-shod infants sitting, bored and listless, listening with praiseworthy patience to deadly details about some plant or animal that they were never likely to see or hear of again; or reading in unison what they did not understand; or reading, again in unison, some simple primer for the third or fourth time.

This detention of defective children which Dr. Hilliard advocates under Poor law conditions, in the familiar barrack school or infirmary, is one that I feel sure public lay and medical opinion in the mass will universally condemn quite irrespective of the cost, and it is obvious that under such a system the cost would be more.

There is need in this great matter for some of us to think Imperially, and it is a significant reflection, in view of Dr. Hilliard's letter, that the joint committee of the London County Council, composed as it was of lay educational experts with a very strong representative and authoritative medical committee, after taking evidence and going thoroughly into the matter, did not make any such suggestions for utilizing the Poor Law to carry out this great work.

Had they done so, I doubt very much whether public opinion would tolerate such a proposition; the stigma of pauperism which Dr. Hilliard so airily insinuates and discusses as applying to the working classes in their relations to our present system of hospital relief and Metropolitan Asylums Board services to the public, is a travesty of existing facts, but the scheme which he now proposes would indeed be a pauperism engrafted upon our educational system of free children, with all its degrading and stultifying social effects. The whole proposal is a retrograde and reactionary step in a great national movement, which should find at least the medical profession united in its action and opinion, and in the vanguard of this public health progress.

The recognition by the State of the necessity for inspection and treatment of defective children in our elementary schools has been brought about mainly by the past work and agitation of medical men and medical public opinion in our press, of which this JOURNAL has taken its full share over a series of many years, and now to suggest that this work—enormous in its extent and of a very special character—should be tacked on to an effete and discredited Poor law system in the throes of transition, would reflect no less discredit upon our profession as citizens and thinkers than to our reputation and sincerity as doctors in the cause of physical deterioration and national prosperity, were it adopted by our Association.—I am, etc.,

MORGAN L. FINCANE, L.R.C.P., M.R.C.S.,
Parish Doctor, late a Guardian and Manager of the Metropolitan
Asylums Board.
London, S.W., Jan. 25th.

FLAGELLATION OF LYMPHOCYTES.

SIR,—Referring to the paper by Drs. H. C. Ross and C. J. Macalister in the JOURNAL of January 23rd, p. 206, I should like to point out that, in relation to a paper on the Etiology of Cancer read by me before the Liverpool Medical Institution in 1899, I exhibited specimens and illustrations of this phenomenon which I had noted in connexion with the cells forming the round cell infiltration occurring in the proximity of minute secondary deposits in the interstitial spaces in sections from a case of cancer of the stomach. Large numbers of the round cells had lost their usual spherical shape, and appeared markedly spiked and irregular. From their surfaces projected fine prolongations, to the ends of which were attached minute oval or diamond-shaped, spore-like refractile bodies, which stained green with the methyl green of the Ehrlich-Biondi-Heidenbain stain. They also stained well with Ehrlich's acid haematoxylin. In fact they responded to stains as does chromatin, particles of which I concluded they were. They resembled miniature spermatozoa, but whether they were in any way connected with cell fertilization it was impossible to determine. Some flagellate bodies were found separate from the cells. Such a conjecture reminded me at the time of the theory, promulgated, I believe, by Klebs and mentioned by Ruffer and Walker¹ in their paper on the so-called parasites of cancer, that one of the functions of leucocytes might be the fertilization of cells throughout the body. Their appearance gave support to a conviction I have always had that, as cell comes from cell, so each must be fertilized to ensure reproduction. This I regard as a definite law, not proved, maybe, by actual demonstration of the phenomenon, but recognized by constant recurrence of effect.² At the time neither myself

nor Professor Sherrington, to whom I showed the specimens, could offer any interpretation of the phenomenon, nor attribute to it any definite significance, as it was found in fixed tissues. It is very interesting to me to find that Drs. Ross and Macalister have noted a similar, or what may be even an identical, phenomenon in living cells.

I have also noticed and described at the Liverpool Medical Institution a somewhat similar appearance in specimens of blood from myeloid leukaemia, which were several times washed and centrifuged in sodium citrate in normal saline solution, then very carefully spread into films and stained with Leishman's stain. Peculiar alterations in contour, which I regarded and described as flagellation, had taken place. From the surface of the large neutrophil myelocytes, and also from the other varieties of mononuclear cells, fine prolongations extended in a form resembling flagella; they were thicker at their attachment to the cells than at their extremity. From some cells only one, from others several, flagellate prolongations were noted. When situated away from the nucleus they were seen to be formed of cytoplasm only. When derived from the cell in close proximity to the nucleus, fine strands of nuclear chromatin substance extended from the nucleus for a short distance into them. In cells containing ruby granules these were occasionally found at the base of these flagellate prolongations. These flagellate prolongations varied in length from one to several times the diameter of the cells. They were to be clearly distinguished from pseudopodia such as one sees in the actively amoeboid polymorphonuclear cells, and as they occurred in the absence of organisms they were not associated with active phagocytosis at the time.³ In a perfect film of blood the lymphocytes show a dual architecture of the cytoplasm. (a) A basophile reticulum with honeycomb-like apertures. (b) Enclosed in this reticulum is a non-granular transparent gelatinous substance in close association with the archoplasm and like it taking on a faint pink with eosin. This material passes out in long, fine prolongations through the apertures of the basophile reticulum, giving to the cell a starred or radiate appearance. These flagellate prolongations must not be confused with the basophile fringes and buds. I should also like to mention that in perfectly fixed specimens of blood, embedded and cut into sections, centrosomes can easily be distinguished and examined in polymorphonuclear neutrophils, eosinophile cells, and neutrophil myelocytes. I have failed to determine their presence in basophile cells, although there is little doubt that they exist.

The large myeloplaxs of the bone marrow also possess peculiar strands of cytoplasm extending from the surface, very similar to the dendrites of nerve cells. In developing bone they are sometimes so regularly arranged as to give the cell a ciliated or, when thicker than usual, a cogged-wheel appearance.

I shall be very pleased to show my drawings and specimens to Drs. Macalister and Ross if they should wish it.—I am, etc.,

ROBERT J. M. BUCHANAN, M.D., F.R.C.P.
Liverpool, Jan. 23rd.

LACTIC ACID FERMENTS FOR PRODUCTION OF SOUR MILK.

SIR,—With reference to your recent editorial on an examination of some commercial lactic ferments,⁴ may I direct attention to certain points in connexion therewith which are very important and often overlooked?

1. The time of incubation (six to ten hours) laid down by some manufacturers is much too short. As your own results show, in the case of solid tablets there is little acid production in ten hours. At least twenty-four hours are necessary to produce an adequately soured milk, and to ensure that the lactic acid organisms are predominant.

2. The organisms are often no longer living in solid tablets. This is serious, as in such cases, though in twenty-four hours or less a curd is often formed, the curd is a rennet curd produced by "lab-forming" organisms not killed by the boiling of the milk, and growing vigorously at such a suitable temperature, in a suitable nidus, and without competition. The result of consuming such a product (which may not be unpalatable) must be

¹ Journ. Path. and Bact., 1902.

² Liverpool Med. Chir. Journ. February, 1900, p. 156.

³ Exhibited by aid of 1/2 in. oil immersion No. 18 eyepiece, Zeiss.

⁴ BRITISH MEDICAL JOURNAL, January 9th, p. 104

highly deleterious and rather enhance the unfavourable bacterial condition of the alimentary canal which the treatment is designed to cure. It is always advisable to test the curd produced with litmus paper in order to ascertain that it is strongly acid and not alkaline.

3. It is necessary to lay stress on the fact that, though all preparations on the market are said to produce "Bulgarian yaghourt," the greater number of them do not contain the organisms isolated from that substance. The principal ferment of this sour milk is peculiar in its properties, acid-producing power, and resistance, and in these particulars is greatly superior to any of the ordinary lactic organisms known to us, and is more adapted to growth in the alimentary canal. These facts, so strongly urged by Metchnikoff, have been largely obscured on account of the greater difficulty found in producing milk soured by the right organism, and because the milk so soured is not quite so palatable as that produced by ordinary lactic acid organisms. It is well to consider whether these objections should be allowed to weigh against the greater value in therapeutic efficiency.

4. The recent work of Critchard, in Metchnikoff's laboratory, explains the reason of failures experienced in the administration of tablets. He has shown that for the full activity of the Bulgarian bacillus an acid environment is necessary. This is easily obtained by the administration of milk soured by the organism, and care must be taken that the milk is really sour and curdled, as otherwise there is no guarantee that the organisms have grown.—I am, etc.,

King's College, London, Jan. 23rd.

R. TANNER HEWLETT.

THE TREATMENT OF SYPHILIS.

SIR,—In his letter of January 9th, p. 123, Colonel Lambkin raises several interesting points.

1. Calomel injections are transitory in their action; therefore they are better suited for an interlude during continuous treatment, their effects are more rapid and transitory than metallic mercury, so that treatment by the mouth can be sooner resumed.

2. The preparation used by Mr. E. Lane is less painful than that used by Colonel Lambkin, so that calomel injections are continued for a longer period. Colonel Lambkin never gives more than eight injections of calomel or metallic mercury, more often six, whereas Mr. E. Lane gives fifteen to sixteen. Colonel Lambkin, after six to eight injections, allows a two months' rest. This would seem to be necessary with the preparation he uses, for, as far as my experience goes, the use of a combination of creosote and camphor is not only unnecessary, but a distinct disadvantage; the injection used by Mr. E. Lane is unattended by pain.

The formulæ suggested by Colonel Lambkin seem capable of various modifications from time to time; thus, in 1903 the use of a basis of anhydrous lanolin and paroline, containing 2 per cent. of carbolic acid, was suggested. In 1907 a basis of palmitine, with a mixture of creosote and camphoric acid, was proposed, whilst now the mixture of creosote and camphoric acid is altered to a combination of creosote and camphor. This would seem to be eminently more suitable, as camphoric acid is not soluble in an equal part of creosote.—I am, etc.,

London, W., Jan. 18th.

T. P. BEDDOES.

THE MECHANISM OF THE ASTHMATIC DYSPNOEA.

SIR,—An essential part of Dr. Auld's interesting lecture on asthma, published in the *JOURNAL*, December 26th, 1908, p. 1850, is a distinct challenge to those who hold that the obstruction in the bronchioles depends on vascular distension, not on bronchial constriction.

Dr. Auld contends that adrenalin given hypodermically relieves the asthmatic dyspnoea by inhibiting the respiratory centre, not by constricting the bronchial vessels. How, then, would he explain the equally rapid relief afforded by inhalation of adrenalin spray? So given the drug acts only locally; neither the respiratory nor any other centre could be affected.

It is unsafe to argue that because it is thin and relatively non-vascular, the bronchial mucosa cannot become turgid at all. It cannot, of course, swell to the extent possible in the nasal mucosa.

Dr. Auld refers to the relatively moderate dyspnoea which characterizes generalized acute capillary bronchitis, and challenges anyone to affirm that the alleged hyperaemia of the bronchial mucosa "could suddenly cause a much greater obstruction of the air tubes than is produced by acute inflammation." There should be no hesitation in accepting this challenge. There are two separable vascular factors in the distension of the bronchial mucosa in asthma:—(1) Vaso-dilatation of the bronchial (not the pulmonary) area; and (2) vaso-constriction of the cutaneous, and possibly other, areas. The latter is at least as important as the former. Hence we may relieve asthma either by constricting the bronchial area (as by adrenalin), or by dilating the cutaneous area (as by the nitrites or general hot baths of any kind). Even more efficient is it to operate on both factors simultaneously as follows—place the patient in a vapour bath from which the face is excluded, and cause him at the same time to breathe cold air through an inhaler containing broken ice.

The reason why the obstructive dyspnoea in generalized acute capillary bronchitis never approaches in intensity to that of a severe asthmatic paroxysm should now be obvious. In acute bronchitis, as in practically all febrile affections, the factor of peripheral vaso-constriction is entirely lacking. Not only is there no added vaso-constriction as in asthma, but even the normal vascular tone is in great part inhibited; as Broadbent has pointed out, "pyrexia as such gives rise to . . . great relaxation of the peripheral vessels." Pyrexia, indeed, acts on the vascular system like the nitrites. Hence an attack of almost any fever, even bronchitis, if sufficiently acute, usually frees the asthmatic from his complaint for the time. There are several classical illustrations. Trousseau noted that throughout an attack of bronchopneumonia a habitual asthmatic slept flat on his back,¹ and Watson relates two cases in which severe asthma was replaced entirely and permanently by acute phthisis.²

The most notable, though not the only, exception to the rule that pyrexia implies relaxation of the vascular periphery is malaria. This is of special interest in this connexion, because it is well known in malarial districts that an attack of ague may take the form of an asthmatic paroxysm (Norman Chevers³).—I am, etc.,

London, S.E., Jan. 15th.

FRANCIS HARE.

THE HOME TREATMENT OF SCARLET FEVER.

SIR.—Dr. Robert Milne, in his paper on the above subject, shows evidence of much genuine faith in his own conclusions, though the data upon which he bases them must be far from convincing to any one who has studied infectious diseases, and scarlet fever in particular, at all carefully.

His main theory appears to be that the infectious agent in scarlet fever is located principally, if not entirely, in the desquamating cuticle.

Not only is it admitted by many authorities (though not yet definitely proven) that such is not the case, but it has even yet to be proved whether the germ of the disease ever occurs in the desquamating skin at all. If such were the case, surely the fine branny scales, shed profusely by most patients, and wafted freely about by every breath of air, would carry infection to large numbers of the susceptible individuals in the immediate neighbourhood of houses or hospitals containing scarlet fever patients. Yet the "striking centres" of scarlet fever is surprisingly small, and such centres do not act to any extent as foci of infection.

On the other hand, it has been most conclusively proved by the classic, if unjustifiable, experiments of Hickler, that the mucus from the mouth and throat of a scarlet fever patient is highly infectious, even when diluted with weak carbolic lotion, till long after the visible signs of the disease have disappeared. It is difficult to understand how Dr. Milne's two-hourly painting of the tonsils (and that only during the first twenty-four hours) with 10 per cent. carbolic oil—itself an antiseptic of very doubtful value under any circumstances—can possibly render them or the throat innocuous. Unfortunately the specific organism of scarlet fever has not yet been discovered, but

¹ *The Pulse*, 1890, p. 85.

² *Chir. Med.*, New Syd. Soc., vol. i, p. 625.

³ *Principles and Practice of Physic*, 4th edition, vol. ii, p. 360.

⁴ *Clinical Researches on Disease in India*, 1860, p. 55.

from our disappointing experience of the utter uselessness of local applications (apart from the merely mechanical effect of douching) in the closely analogous disease, diphtheria, in which bacteriological verification can be obtained throughout the course of treatment, it is highly probable that Dr. Milne's procedure of tonsil painting has no other effect than that of relieving symptoms. How does Dr. Milne explain the by no means uncommon occurrence of "return" cases where the "infecting" case had finished desquamating long before, and had no unhealthy abnormalities, such as rhinorrhoea or otorrhoea, evident? Also the non-occurrence of "return" cases where children have been sent home from hospital while still desquamating freely, and without having undergone any kind of skin inoculation? His explanation of the "return" cases quoted by him is, to put it mildly, a trifle far-fetched.

Much careful work on this subject has been done by Millard, Priestley, Lauder, and more recently by Simpson, Cameron, and Mervyn Gordon, to name only a few of the observers on strictly scientific lines, and doubtless they would hail with delight the discovery of so simple a way out of the great difficulties surrounding this complex question were it ever proved to be efficacious.

The use of eucalyptus oil for inoculation is not as unknown to a "conservative" profession as Dr. Milne suggests. There are few fever hospitals of any importance in the country that have not at some time or other, I imagine, made trial of it and found it both troublesome and of little or no value, besides being most unpleasant to the unfortunate sufferers, whom I myself have known to cry for long enough after the oil had been applied to the scalp, for instance, on account of the stinging of the eyes which resulted.

What possible effect this inoculation of the skin can have upon the throat Dr. Milne alone knows. Perhaps the action is the same as that of the whitewash on the scriptural sepulchres. To "keep the aroma in the rooms, and sprinkle a little (of the eucalyptus oil) on the beds day by day," is doubtless most gratifying to those who like the smell; but has anyone ever yet heard of a mere aroma killing microbes?

With the number of notifications of scarlet fever throughout the country showing no diminution year by year, but rather the reverse, for which the existence of unrecognized cases is largely blamed, is it not most unjustifiable for known cases, while still undoubtedly in an infectious condition, to be deliberately turned out amongst the general community to mingle freely with them? While exposing themselves in public places and in public conveyances, how does Dr. Milne know how many persons of whom he never hears his patients may have infected, directly or indirectly? That he believes his cases to have been rendered free from infection, on such grounds as he has set forth in his paper, will hardly carry weight against the scientific evidence to the contrary.—I am, etc.,

Newcastle-upon-Tyne, Jan. 25th.

HAROLD KERR.

SIR,—I can verify the statement of Dr. J. Sadler Curgiven in the *BRITISH MEDICAL JOURNAL*, p. 251—namely, that the credit of the eucalyptus treatment is due to his father, Dr. Brendon Curgiven. In the *BRITISH MEDICAL JOURNAL*, March 29th, 1890, is a report of a paper read by him before the Epidemiological Society, and in the *BRITISH MEDICAL JOURNAL*, October 26th and November 23rd, 1889, are communications on the same subject. I can well remember reading these at the time, and purchasing some of the special eucalyptus oil—"olensaban." I think it was termed—which I used on every case I came across in my practice at that time.—I am, etc.,

St. Leonards, Jan. 24th.

PERCY NEWELL.

OEDEMA OF THE EYELIDS WITH PYREXIA.

SIR,—With reference to the article by Dr. Charles R. Bigood in the *JOURNAL* of January 9th, p. 88, I cannot help noticing the similarity of the symptoms present to those which occur in mild cases of trichinosis. In fact, the pyrexia and constitutional disturbance associated with marked gastro-intestinal symptoms and transient oedema of the eyelids would, in the absence of proofs to

the contrary, at once raise in my mind a suspicion of that disease, which I am inclined to consider more prevalent than is generally suspected. The demonstration of eosinophilia on examining the blood and the finding of adult trichinae in the stools would, of course, easily establish the diagnosis.

That some of the cases should arouse a suspicion of enteric fever was not to be wondered at, as this disease and acute rheumatism are the affections most likely to be confounded with trichinosis, the latter when the young trichinae are migrating in the tendons near joints.

The amount of prostration present seems to vary greatly. I have seen a patient with a high temperature apparently suffering little inconvenience and asking to be allowed out of bed.—I am, etc.,

CHRISTOPHER L. W. BUNTON, M.B.,

Plymouth, Jan. 16th.

Fleet Surgeon, R.N.

PERNICIOUS ANAEMIA AND PYORRHOEA ALVEOLARIS.

SIR,—Dr. Byrom Bramwell's interesting note on pernicious anaemia appears to be incorrect in one particular, which is remarkable, as he appears to have considered the condition as possibly due to oral sepsis.

The evidence was clear before him as to the presence of typical pyorrhoea alveolaris at a recent date. "The teeth dropped out." This was absolutely diagnostic of the presence of this disease. The absence of pyorrhoea should always be carefully noted by a dentist who recognizes its less obvious symptoms and signs.—I am, etc.,

London, W.

C. WYNN WIRGMAN.

THE APPLICATION OF MENDELIAN RULES TO HUMAN INHERITANCE.

SIR,—I am sorry that Professor Pearson is unable to understand my letter in the *JOURNAL* of January 2nd. I do not think he can have read it carefully, for there is no reason whatever to conclude that I should interpret his illustrative case in the way he assumes. Mendelians would here reckon four normals and two abnormal. If this were a part of Nettleship's chart, I should include all the normals; but if either or both of these abnormal had only normal children I should not count these (that is, the children), but stop at the last abnormal in the vertical line of descent. If, on Nettleship's chart, any abnormal has only had normal children, and these are not counted, then there are 134 abnormal out of 274 descendants (of abnormal), and this gives a percentage of 48.9, which is near enough to the 50 per cent. to claim it as Mendelian.

This being what I have done, Professor Pearson has put a wrong interpretation on my words, and though he quoted me correctly as far as the quotation goes, he ought to have finished the sentence. He says his interpretation is the only one he can put on my words, "if we stop at and include the last abnormal," but this quotation stops in the middle of a sentence where there is not even a comma. What I said was, "If we stop at and include the last abnormal (+ brothers and sisters) in each line of descent."

Why Professor Pearson concludes that I should (in his illustration) not reckon the three normals "the tail of the offspring" I cannot imagine, seeing that I distinctly say "+ brothers and sisters," for surely the word "include" refers to them as well as to the last abnormal. Now, if the last abnormal in each line of descent in Nettleship's family had had no children there would have been no doubt about the chart being Mendelian.

It may be that my method of counting is not correct, and that one is not justified in omitting the children of "last abnormal," and yet one cannot help being struck with the fact that of the 98 abnormal parents so many as 31 have had only normal children, and, in the absence of any other explanation, I suggested the theory contained in my last letter.

The real point at issue is, Does Nettleship's chart conform to Mendel's law of inheritance, or does it not? I contend that up to a certain point—the last abnormal—it does. Professor Pearson, including the children of these abnormal, says it does not; but until one knows why so many (31) affected individuals should not have any abnormal offspring I cannot see that we are justified in taking Professor Pearson's view expressed in his first

letter, that "the odds are several million to one against Nettleship's material being a sample of a population obeying Mendel's rules."—I am, etc.,

Wrexham, Jan. 20th.

H. DRINKWATER.

THE CAUSATION OF INGROWING TOENAIL, AND THE LOCATION OF GOUT.

SIR,—The dear old textbooks may often be in the wrong, but it is seldom that they are proved so to be, and I do not think their integrity has been shaken by Dr. Arbour Stephens's observations on the above subjects in the *BRITISH MEDICAL JOURNAL* of January 16th, 1909.

First, if pressure from contact with the bed during sleep were the cause of ingrowing toenail, this condition would invariably occur at the inner side of the big toe; but it does not, it is quite common at the outer side of the big toe. Secondly, in the position depicted by Dr. Stephens (Fig. 1) the right foot is supported by the resting of the right internal malleolus on the inner side of the left heel, and the right knee is supported on the left knee, and there is no strain whatever on the right big toe, and no pressure worth considering. This also disposes of Dr. Stephens's theory of the location of gout. Fig. 2 calls for no comment beyond the fact that it is a chronic partial luxation due to the continued wearing of pointed boots.

Is there, after all, a necessity for finding a sole cause (forgive the phrase) for the so called ingrowing toenail? Pressure, dirtiness, traumatism, including a wound by the corner of the nail, may be causes, continued pressure being always a contributory cause.

In two cases, recently under observation, the nails were cut close to the quick, leaving a sharp corner at either side, and it is clear that a slight lesion of the soft parts can be thus started, and a chronic inflammatory condition kept up indefinitely.

The location of gout is generally admitted to be determined by exercise, and as people spring off the big toe in walking, this toe-joint is a very usual sufferer. Gravity congestion is probably often contributory. The fact that the gouty attack is often first noticed on waking requires no more explanation than does muscular stiffness at the same hour, and is due to the slowing of the blood current during sleep, which favours exudation.

A patient of mine, who generally walks, once cycled when "gouty," with the result that the patch of gout occurred the next morning on the right instep instead of the usual right big toe.

Long-continued pressure can cause a localized gouty manifestation, for I have seen it in the elbow and heel in gouty subjects confined to bed for a week or two—I am, etc.,

Tamworth, Jan. 20th.

CHARLES H. JOY.

THE ACTION OF ALCOHOL ON PROTOPLASM.

SIR,—In the *JOURNAL* of April 18th, 1908, Mr. Kesteven wrote an interesting account of the paralyzing and destructive action of alcohol on amoebae when they were immersed in solutions of it varying from 1 to 7 per cent., and seemed to have been struck with the fact that it had no stimulating effect. Did he calculate how much alcohol would be in his body if every one of its cells was bathed in a 3 per cent. solution, and consider what his condition would probably be?

Not far from the same time I saw an account of a similar experiment with paramoecia, but in that case with solutions of only from 1 in 1,000 to 1 in 5,000, and with a result just the opposite to that obtained by Mr. Kesteven. The little animals underwent their multiplications by division several times as often before they died out as when they had no alcohol, and showed greater activity and vitality all the time.—I am, etc.,

Tonbridge Wells, Jan. 18th.

EDW. G. GILBERT, M.D.

CONFERENCE ON THE MEDICAL PROFESSION AND FRIENDLY SOCIETIES.

SIR,—I do not know what is the main object of the conference which is to be held in London on Saturday, February 6th: but as we have given considerable attention to this subject in Lancashire, I may be allowed to make two or three remarks.

We are of opinion that the position and circumstances of the working man have very greatly improved since

friendly societies were first formed, and that in most cases no corresponding increase has been made in the rate of remuneration of the medical officers.

Through the fact of having medical officers attached to a club their services have been exploited, with the result of considerable advancement and prosperity to it, and so also with regard to industrial assurance companies, for which we have been paid a merely nominal fee. Think of the millions some of these have in reserve, and the part the profession has played in this accumulation. A charitable feeling on our part at first probably had some place, but for many years many medical men have smarted considerably at attending men who were earning increased wages, and well able to pay ordinary fees, and saw no way of altering the condition of affairs.

Now that the profession is getting better organized, there is more hope that something definite can be done. Whilst we have no objection to no restriction being made as to those joining a friendly society, what we contend for is that medical benefits should only be available for those whose wages are below a certain standard. Therefore, the first thing to contend for is a wage limit, and this may be made to vary in town and country.

And so in regard to the remuneration. There should be a hard-and-fast rule that 4s. per annum should be the minimum rate of payment for the medical officer, but in large towns it should not be less than 6s.

These things can be easily obtained by union and organization and the ventilation of opinions in our *JOURNAL* and at meetings such as the one referred to above.

I feel somewhat concerned in reference to this meeting, as I do not see many names on the card of invitation who have been prominent in the past in dealing with the subject of friendly societies; and I certainly feel that it would be a great sacrifice to attend such a meeting at this time of the year except there would be likely to be some tangible advancement of the subject. On the other hand, for men to stay away who are conversant and have been for many years would be a great mistake if such a meeting went wrong by not having a controlling force present.

As there is some doubt as to my being able to be present I shall feel obliged if these fragmentary remarks can be read by those able to attend.—I am, etc.,

8, Ardwick Green, Manchester,
Jan. 26th.

G. H. BROADBENT.

THE DEPARTMENTAL COMMITTEE ON THE MIDWIVES ACT AND GENERAL PRACTITIONERS' INTERESTS.

SIR,—Sir William Sinclair has done good service to the general practitioner by drawing his attention through the *JOURNAL* of January 23rd to the formation of this committee by the Privy Council.

There is no doubt that in 1902 the medical profession was caught napping. There will be no excuse for us if we lose the opportunity now offered to amend the Act, and the present rules of the Central Midwives Board which are only in force until September 30th next.

The British Medical Association has been asked if it desires to tender evidence. The reference to the Departmental Committee is:

To consider the working of the Midwives Act, 1902, and in particular with reference to the supply of midwives and the cost of training, the remuneration of medical men summoned on the advice of midwives under the rules in pursuance of the Act, and the delegation of their powers by County Councils under the Act.

There seem to be four principles that should be urged:

1. Adequate and immediate representation of the general practitioner by general practitioners nominated by the Association on to the Departmental Committee.
2. Adequate representation of the general practitioner by general practitioners elected by the Association on to the Midwives Board.
3. Adequate guaranteed payment for services rendered to the State by attendance given before, during, and after labour.
4. No State subsidizing of midwives.

With these acceded to, the profession can rest content that the Act will not so grossly be able to be worked to the detriment of the doctor or of the woman and child for whose benefit it has been enacted.

Will every general practitioner, therefore, at once bestir himself and take steps to induce his local medical society (or Division of the Association, Branch Council or Executive Committee of the Division) to put at the disposal of the Association evidence on the four points referred to the committee, as also a resolution in favour of the four principles enumerated above? Time is valuable.—I am, etc.,

London, S.W., Jan. 26th.

E. ROWLAND FOTHERGILL.

THE PUBLIC HEALTH COMMITTEE'S REPORT.

SIR,—If further proof is required of the desirability of the opinion of the Association being taken by a poll of its members instead of by meetings of the Divisions, it can be found in the report of the Public Health Committee. It most fairly states both sides of the question, and is an admirable example of how a report should be drawn so as to inform the members of the *pros* and *cons*, and to obtain their opinions by means of a poll.

The decision to formulate a "declared policy" of the Association on the question of the "desirability of health officers being required to give their whole time to the work" is one of far-reaching importance, and I venture to say that the method of ascertaining the opinion of the members through meetings of the Divisions as at present constituted is likely to give an absolutely wrong impression of their views.

The question is one which affects practitioners in rural districts, whether medical officers of health or not, to a far greater degree than those who practise in the large towns; in fact, as the latter already have whole-time health officers, the question only affects the practitioner in the town to a very minor extent. Yet the meetings of the Divisions, being held in the towns, will be attended by about half a dozen members residing close at hand, and the rural medical officer of health and practitioner will, as usual, be conspicuous by his absence. This half-dozen will probably, after a brief discussion, unanimously pass a resolution the drift of which is a foregone conclusion, and the "declared policy" of the Association on this matter will be settled.—I am, etc.,

Gunnislake, Jan. 25th.

ALBERT BOWHAY.

GRATIS PATIENTS.

SIR,—It is ridiculous for a doctor who is making a moderate income to expect his family to be attended for nothing by a general practitioner.

The case is rather different with regard to the services of a specialist, to whom we as doctors have other means of making amends.

Personally, I always pay fees to my family's doctor; but I do so in a proper way, and therefore always succeed in getting the fee accepted.

I think we as a profession are at fault in not accepting fees when they are offered; but, alas! the offer is not always forthcoming. The whole system is an abuse.

Not long ago, a retired surgeon-colonel, holding a Government appointment, brought his child to me. The child needed tonsils and adenoids removed. "You will be able to do the operation in your consulting room, I suppose?" said he. I did what was necessary, but not in my consulting room, and I was never even thanked. This was a man with an income of at least £800 a year.—I am, etc.,

January 17th.

F.R.C.S.

INTERNAL INJURY WITHOUT EXTERNAL BRUISING.

SIR,—To judge from discussions that have arisen from time to time with medical friends there seems to be a wide variation of opinion as to the amount of damage that can be inflicted on the internal organs without injury to the skin and superficial structures. The paper in your issue of 16th inst. by Dr. Marten Payne is a valuable contribution to the physics of the subject, and it should help largely to dispel the misconceptions that we sometimes come across, especially in cases that come into court.

Some years ago, when I was in the East, a man was brought in dead, having been killed in a row with another man. At the *post-mortem* examination he was found to have the second to tenth ribs fractured on one side, and the first to tenth on the other. The lungs were badly

ecchymosed and the heart ruptured; liver, stomach, kidneys, transverse colon, and spleen all lacerated more or less.

In court the witnesses for the Crown all stated that these injuries were produced by "prodding" in the chest with the sawn end of a bamboo used bayonet fashion.

Now, with all these extensive injuries to the internal organs, there were no marks of violence on the front of the body except a severe bruise and slight scalp wound on the left frontal protuberance. The picture presented to my mind was that of a typical buffer accident, and one had no difficulty in coming to the conclusion that the man had first been knocked down and then jumped upon, which subsequently proved to be the case.

I had also many years ago a case of a child aged about 5 years run over by a hansom cab conveying three men and the driver; there was severe contusion and laceration of the lungs, but no skin or rib injury. Any medical man with tropical experience can call to mind many cases of ruptured spleen with no external marks of violence. My object in writing is, if possible, to get a definite expression of opinion from those who have exceptional opportunities of forming one, in order that there may be a diminution in the number of such discrepancies in evidence as is instanced in your correspondent's paper.—I am, etc.,

Bedford Park, W., Jan. 19th.

J. SHEPLEY PART.

Public Health

VITAL STATISTICS IN ENGLAND AND WALES (1908). We are indebted to the Registrar-General for the following rates, compiled and published for the convenience of medical officers of health. The figures are provisional and subject to revision.

ENGLAND AND WALES.

Annual Birth rates, Death-rates, and the Death-rates from the Principal Epidemic Diseases.

	Annual Rate per 1,000 Living.			Deaths Under One Year to 1,000 Births.
	Births.	Deaths.	Principal Epidemic Diseases.	
	Crude.	Corrected*		
England and Wales	26.5	14.7	1.29	121
76 great towns ...	27.0	14.9	1.59	128
142 smaller towns...	26.0	14.0	1.26	124
England and Wales less the 218 towns	26.2	14.7	1.38	110

* The corrected death-rates are the rates which would have been recorded had the sex and age constitution of the populations of the several areas been identical with that of England and Wales as enumerated in 1901.

COSTS OF DISINFECTION.

In a case heard by Judge Selge at the West London County Court on January 15th the question whether the landlady of furnished rooms can recover the cost of disinfecting them was considered. It appeared that the rooms had been taken for a consumptive patient by the defendant. The plaintiff, who let the rooms, was not told that the proposed tenant was in an advanced stage of consumption. After the death, which took place in four days, the landlady expended £2 5s. on disinfection, and judgement was given for this amount. It is interesting to notice that the only other reported case on the subject came before the same judge when sitting at the Folkestone County Court in 1899 (see *Law Times*, 1899, vol. cvii, p. 101). There an innkeeper sued the executors of a guest who died of consumption for the cost of disinfection. It was held that the costs could be recovered on the ground that the law would imply a contract on the part of the guest to pay for any extra expense properly incurred by the innkeeper as a consequence of the infection of the guest. His Honour also decided that on the evidence of the medical officer of health consumption was an infectious disease, and that it would be dangerous to let the rooms again without disinfection.

THE INSPECTION OF MEAT.

In a recent report, Dr. Robertson, M.O.H. for Leith, stated that no two towns at present had the same system of meat inspection. There was no reason why there should not be a standard. The danger from the consumption of tuberculous meat had been exaggerated; the tubercle bacilli were seldom located in the substance of animal flesh. At present there were instances in which a carcass quite fit for human food was condemned, the butcher having to bear the entire loss.

Obituary.

GEORGE EASTES, M.B.LOND., F.R.C.S.ENG.,
FORMERLY TREASURER AND PRESIDENT OF THE METROPOLITAN
COUNTIES BRANCH.

THE announcement of the unexpected death of Mr. George Eastes, at one time Honorary Secretary and for many years Treasurer of the Metropolitan Counties Branch, has been received with great regret by all members of the British Medical Association who knew, if only by report, the enthusiastic interest he took in its welfare, and the time and energy which he devoted to work for it as the occupant of the offices mentioned, as a member of the Central Council, and in other capacities. Those who had the advantage of Mr. Eastes's personal acquaintance will miss in him a staunch friend, always ready, not only to offer sound advice, but to take infinite trouble, and give unsparing labour to the study and elucidation of any matter affecting the honour and interests of the profession.

George Eastes was born on May 16th, 1841. He was the eldest child of Mr. Silvester Eastes, M.R.C.S.Eng., J.P., Mayor of Folkestone, who at that time occupied a house in the old town, which clustered round the harbour, while fields, as he remembered, then extended on the West Cliff right up to the old parish church. His first school was at St. Margaret's Bay. He then went to Tonbridge Grammar School, where a somewhat severe rule prevailed, for the boys were compelled to rise at 5 a.m. and work till breakfast at 8 a.m. Later on he was transferred to Maidstone School, and then, after the signing of the peace following the Crimean war, he wrote a competition poem on "Peace," for which he gained the first prize. Leaving Maidstone, where he had chiefly distinguished himself in mathematics, at the age of 15, he was apprenticed to his father, and worked in his surgery till October, 1860, when he entered Guy's Hospital. While pursuing his first year's work he saw the advantage of a London University degree, and passed the matriculation and Preliminary Scientific Examinations of the University of London in rapid succession. In 1864 he passed the Intermediate M.B. examination, and obtained the diploma of M.R.C.S.Eng. In 1866 he graduated M.B. and took the diploma of L.R.C.P.Lond. He took the diploma of F.R.C.S.Eng. in 1868. He served as House-Surgeon at Guy's Hospital, and was afterwards appointed Surgical Registrar and Tutor, a post he held for two years. During these years he was a close friend of Hilton Fagge, Phillips, Oliver Duke, and of his seniors he had the profoundest affection for Hilton, Cooper Forster, Moxon, and Gull. In 1868 he succeeded Dr. Egbert Charlton in practice at 5, Albion Place, London, W. He married, on February 9th, 1869, Fanny Elizabeth Friend, of Hambledon, Hants, who with three children survives him. During the years of general practice he displayed great activity in all matters connected with the profession. In 1871 he published a

Memoir of Harvey, who was a native of Folkestone; and during the succeeding years he started, and almost solely by his unaided personal efforts raised, a fund for a memorial to Harvey, which took shape ultimately in the statue on the Lees at Folkestone which was unveiled in August, 1881.

His close connexion during these early years with the Guy's surgeons brought him much anaesthetic work. He was one of the founders of the Society of Anaesthetists, and for fourteen years was Anaesthetist to the Great Northern Hospital; it was in this sphere that he performed some of the most laborious work of his life. He was Secretary of the first committee appointed by the British Medical Association to inquire into the various anaesthetics, their uses, modes of administration, dangers, etc.; thousands of communications were received, and to the labour of tabulating results, in which to some small extent his family participated, he nightly devoted many hours. His report was published in the fourth volume of the *Transactions of the Society of Anaesthetists*.

Mr. Eastes joined the British Medical Association early in his career, and was elected Honorary Secretary of the Metropolitan Counties Branch in 1886. He retired in 1888, and four years later was elected Treasurer of the Branch, an office which he retained until 1899. In 1900 he became President, delivering in that capacity an address on *Our Numbers and Our Work at the Close of the Century*. In 1901 he again accepted office as Treasurer, and finally gave it up in 1903, being elected Vice-President of the Branch in the following year. He was Secretary to the Collective Investigation Committee of the Branch from 1885 to 1887. He was also for many years, and down to last July, a Representative of the Branch upon the Central Council, and for part of that period was an active and useful member of the Journal and Finance Committee. He was Secretary of the Section of Public Medicine at the Annual Meeting in 1889, and Vice-President of the same Section at the Annual Meeting in Newcastle in 1893.

At some date, which cannot now be definitely ascertained but probably about 1874, Mr. Eastes joined the staff of the *BRITISH MEDICAL JOURNAL*, and for a good many years, under the editorship of Mr. Ernest Hart, took an active part in the working, serving for some years as a sub-editor along with Mr. Dorn and the late Dr. Fancourt Barnes. He always maintained his interest in journalistic work, and was an occasional contributor to our columns down to the time of his death. In this work, as in everything else to which he turned his attention, Mr. Eastes showed himself a man of sound and temperate judgement, ready to take any pains to master his subject, and possessing an admirable power of stating a difficult and complicated subject with lucidity.

He was an active member of the Royal Medical and Chirurgical and of the Obstetrical and Clinical Societies of London, as well as of the Harveian Society. Of the last named he was President in 1895, and delivered

an address on Evolution in Treatment from 1831 to 1895.

He was secretary and one of the founders of "The Guyite Club, 1863," which post he held from its initiation to the time of his death. It originally had forty-three members, of whom now only fifteen survive. In this little society much of his love and constant loyalty to old friends was exhibited, and amongst these few old Guy's friends his memory will be cherished *Dum taceat nobis* (the motto of the club).

In his home his chief characteristic was his absolute truthfulness, honesty of purpose, and belief in the goodness of others. Method and accuracy ruled his every action. Early in life he was fond of riding, shooting, and the sea, and possessed a veritable passion to get to the top of a hill to take a wide view of Nature. Later in life he indulged to a small degree a strong wish to travel. His practice was not at first very lucrative, and for long he had had to battle with pecuniary difficulties, and only finally successfully won the battle at quite a recent date. But he never allowed these anxieties to interfere with his public work, nor with the genial greeting which he always had for friends old or new.

Mr. Eastes seemed to those who knew him well to have aged a good deal during the last few years, but he experienced no symptoms of an alarming character until January 18th, when he had a severe attack of pain; at the same time he was suffering from catarrhal symptoms, and was advised to keep the house. After a few days' rest he appeared much better, but on January 23rd he had a recurrence of the pain, and almost immediately expired. The first part of the funeral service, conducted by the Rev. Prebendary Gurdon, was held at Christ Church, Lancaster Gate, on January 27th. It was attended by a large number of his old friends and colleagues, including Sir Jonathan Hutchinson, Dr. Frederick Tayler, Mr. Butlin, Dr. F. T. Roberts, and Mr. Alban Doran: the British Medical Association was represented by Mr. Edmund Owen and Mr. Guy Elliston. The interment took place at Folkestone Cemetery on the same day.

We regret to record the death of Dr. SYDNEY SHAKSPERE BROADBENT, of Penton House, Hanley, Staffordshire, at the age of 57. His health began to fail at the beginning of last year, and in July the renal trouble from which he was suffering developed materially. It caused him much suffering, but in spite of it he grappled manfully with his duties, and it was not until about ten days previous to his death, at the beginning of December, that he finally gave up work. Dr. Broadbent, who was born in Stalybridge, received his medical education at Sheffield Medical School, and in 1896 became L.R.C.P., L.R.C.S. Edin., and L.F.P.S. Glas. A few years later he settled down in practice at Hanley, where his kindly disposition made him very popular with his patients. Outside his work he figured very little in public, except in connexion with St. Jude's Church, at which he held the office of churchwarden. He was often to be seen, however, at meetings

of the local Branch of the British Medical Association, of which he was a member, and was well esteemed by his colleagues. A man of artistic tastes and quiet unobtrusive manner, he did much good in his life, and exercised a healthy, refining influence on those about him. His funeral was attended by a large gathering of his old patients and personal friends, who thus testified to the high regard in which they held his professional qualities, and to their esteem for him as an upright, honourable man. Dr. Broadbent was married, and leaves a widow but no children.

Dr. GEORGE DICKSON died at his residence, 9, India Street, Edinburgh, on January 18th, in his 71st year. His whole professional life was spent in Edinburgh. He graduated M.D. Aber. with honours in 1864, and took the diploma of F.R.C.S. Edin. in 1882. He was a quiet and unobtrusive man, who had many warm friends; he was a notable Freemason, and was so highly esteemed by his brother Masons that there was scarcely a lodge in the district of which he

was not an honorary member. He was connected with the Lodge of Edinburgh Mary's Chapel, No. 1, for forty years, and for five years, from 1891, was Right Worshipful Master. He was associated with the Grand Secretary and the late Past Master in editing the history of the lodge. At the time of his death he was Librarian and Historian of the lodge, and he devoted much care to the old minutes, which are in existence from July, 1599. He was a prominent member of the Grand Committee of the Grand Lodge. He was Secretary of the lodge when the King (then Prince of Wales) was made a member of the lodge, and one of Dr. Dickson's treasured possessions was the pen which the Prince of Wales used on that occasion. At the tercentenary celebration of the oldest minute of his lodge Dr. Dickson was presented with his bust by the brethren of the lodge. A year ago, at the annual festival, after the election

of the office-bearers of his lodge, Dr. Dickson was presented with a beautiful silver salver in recognition of the affection and esteem in which he was held by the brethren of the lodge. He used to say that he could count his absences from the lodge on the fingers of one hand. He is survived by a widow, one son, and three daughters.

We have to record the death of Dr. LORRAINE, of Hawick, which occurred on January 12th, after an illness of about three months. Born fifty-six years ago, Dr. Lorraine took the diplomas L.R.C.P. and S. Edin., in 1879. After spending three years in Colorado and Texas, he returned to Britain, practised in England for a short time, and then settled down in Hawick. He held the appointment of Medical Officer to Stobs Camp. He is survived by a widow and family.

THE German Surgical Congress will hold its thirty-eighth annual meeting this year in Berlin, from April 14th to 17th, under the presidency of Professor H. Kummel, of Hamburg.

necessary, having regard to the fact that there was to be a new trial.

Lord Justice Farwell and Lord Justice Kennedy concurred, and a new trial was ordered, the plaintiff paying the costs of the appeal; the costs of the first trial to abide those of the second.

AN ACTION FOR LIBEL.

MACLEOD V. MULLOCK AND TRIPP.

In this case, which was heard by Mr. Justice Lawrence at the Suffolk Assizes on January 22nd and 23rd, the plaintiff sought damages against the defendants for libel.

Mr. F. E. Smith, K.C., and Mr. Hansell were for the plaintiff; Mr. Hohlner, K.C., and Mr. Wild for the defendants. Mr. H. C. Dickens watched the case on behalf of the British Medical Association.

According to the statement of claim, it was alleged that in or about the early part of May, 1905, the defendants, acting by the defendant Mullock, falsely and maliciously wrote and published of the plaintiff and of him in his profession to Dr. Wilson Tyson a letter which contained the following statements:

"Dr. Macleod tried to get the use of a bed for one of his patients at the Southwold Hospital without asking the permission of the staff. . . . Dr. Macleod also touts for patients, and I will give you a specific instance of this. On May 2nd he approached a patient of mine who is the caretaker of the local golf club, and the following conversation ensued: 'You are looking very badly?' 'I have one of my headaches,' she replied. 'I must give you something for it,' said he, 'but as I cannot examine you here, come round to my house to-morrow, and I will see what I can do for you.' She demurred, but he over-persuaded her. She went to his house, and he kept her there for one and a half hours, and examined her eyes, etc. I heard a rumour of this on the 4th inst., and went at once to my patient, where she told me exactly what occurred. She said she had no wish to leave me, and was quite satisfied with the way I had always treated her and her family. . . . Dr. Macleod is guilty of a breach of professional etiquette. He gets his wife to call on my patients, and she occupies herself in advertising his successes and in insinuating that he has knowledge and experience superior to that possessed by other men practising locally. . . . I should also add that Dr. Macleod gave Dr. Tripp and myself a promise that if he were called in to see any of our patients he would inform us of the fact. This promise he has repeatedly broken."

The defendants pleaded privilege. They said that they were members of the British Medical Association, one of the objects of which was the maintenance of the honour and int. res of the medical profession. They further alleged that Dr. Wilson Tyson was at the time the Secretary of the North Suffolk Division of the Association, of which Division the defendants were members, and that it was the duty of Dr. Tyson to inquire into and deal with any matters affecting the maintenance of the honour and interests of the profession. They therefore had a common interest with Dr. Tyson.

Mr. F. E. Smith, in opening the case, said that his client had at one time been a member of the British Medical Association, but since he had resigned that body had no jurisdiction over him, and he would contend that the defendants had no right to make complaints about him to the Medical Association. The plaintiff came in March, 1907, to settle in Southwold, where the two defendants, Dr. Mullock and Dr. Tripp, were already in practice. In May, 1903, Dr. Mullock, acting on his own behalf and on that of Dr. Tripp, wrote to Dr. Tyson, the honorary secretary of the local Division of the British Medical Association, of which the defendants, and not the plaintiff, were members, the letter quoted above. Dr. Tyson, having consulted his committee, and having received a telephonic communication from the defendants leaving the matter in his hands, communicated by letter with the plaintiff, specifically indicating the charges which the defendants had made against him, and offering the arbitration of the British Medical Association should he desire to offer any explanation. The plaintiff, in answer, wrote refuting the various charges made, and expressing a hope that the influence of the Association might result in a retraction and apology by the defendants, though he did not admit its authority to decide such a serious matter. No apology being forthcoming, these proceedings were commenced.

At the commencement of the plaintiff's case Dr. Bateman, Secretary of the Medical Defence Union, was called to produce a letter from the defendants. He objected to do so on the ground that it was privileged.

Mr. Justice Lawrence ordered it to be admitted.

The plaintiff then gave evidence, in the course of which he refuted the charges made against him in the letter above set out.

Other witnesses in support of the opening having been called, Mr. Hohlner submitted that the occasion was privileged, whereupon Mr. F. E. Smith said he was quite satisfied to treat the occasion as privileged, and to submit the question of malice to the jury.

The defendants both gave evidence, and said that they felt justified on the facts before them in going to the British Medical Association for advice, and that they did not expect Dr. Tyson to communicate with the plaintiff. They denied the existence of any malice towards the plaintiff. They still believed the charges made to be true, but had not justified on the advice of

their solicitor, there not being sufficient legal proof of the facts alleged.

His Lordship, in summing up, said, according to the report in the *East Anglian Daily Times*, that there was no doubt that the occasion on which the defendants wrote the libel was privileged, and the question was whether the defendants had forfeited the advantage of this by not using it rightly. In order that the privilege might be good, it was necessary that the words should not be malicious, if true. Malice would be established if it could be shown that the defendant had some indirect motive, or some spite. The first thing to inquire into was whether the words used were true. If a defendant said the words were true, and proved them to be true, there was an end of the matter. If he did not do that, the door was open to him to say that he honestly believed that what he wrote was true. There was also a middle position. If a man recklessly it was true or not, that this kind, not making inquiry whether it was true or not, that was malicious, and that was the question they had to ask themselves in this case, and also whether these gentlemen had some indirect motive. There might, for instance, be jealousy of a new doctor coming to Southwold. The question was whether, when Dr. Mullock wrote the letter to the secretary of the Division of the British Medical Association, he was using the occasion honestly, or was abusing it. If a person on such an occasion stated what he knew to be untrue, there would be no doubt that he was abusing the occasion, but there was a state of mind short of telling a deliberate falsehood by which a person might be held by a jury to be abusing the occasion, and in that sense to have spoken maliciously. If a person, through being very angry, or from some other wrong motive, allowed his mind to get in such a state as to make him cast aspersions on another person recklessly, not caring whether they were true or false, a jury would be justified in finding that he had abused the occasion. It had been said that anger would be such a state of mind, and he thought a gross and unreasoning prejudice would be such a state of mind. Dealing with the letter itself, he said that there was a reference at the outset to the plaintiff going to Southwold. He, of course, had a perfect right to go there. If there came to-morrow a cloud of ten thousand doctors to Southwold, they would have a perfect right to go there, though, of course, nobody would help it. A point had been made that they could possibly help it. A point had been made that in the letter to Dr. Tyson the defendants only asked for advice. Asking for advice did not make an untrue statement. There was one thing to be learnt from this case, and he thought it would be very useful to all of them. They must remember that when they went to a doctor he thereby acquired some interest in them until the day of their death. It might be desirable when they went to a doctor to begin with the remark, "and the patient without prejudice." If they did not say that, the doctor might pursue them to the end of their lives. He would never let them go if he could help it. After dealing with other portions of the letter and the allegations contained in it, his lordship concluded by saying that Dr. Tripp had nothing to do with the letter of May 14th to Dr. Bateman, and if the jury took a more serious view of the case because of that letter, that ought not to be visited on Dr. Tripp, but it ought to be visited on Dr. Mullock.

The jury returned a verdict for the plaintiff with £300 damages. Judgement accordingly.

WORKMEN'S COMPENSATION CASES.

Cardiac Strain.

JAMES COE v. THE FIFE COAL COMPANY was an arbitration under the Workmen's Compensation Act, before Sheriff-Substitute Hay-Shennan at Dunfermline, in connexion with an injury sustained by the appellant, Coe, while in the employment of the Fife Coal Company. Coe, along with two other men, was engaged in driving a heading off the main level up to a gradient of 1 in 35. The heading had been driven about 60 ft. up. Rails had been laid down, but no wheel had been put up, and the men had to let the full buckets down the steep gully by hand. The work involved great strain. The appellant had repeatedly complained about the want of a wheel, and on May 1st he refused to go to work on this ground, but did go on the promise that the matter would be attended to. When letting down the ninth or tenth bucket he felt a sudden pain in his chest, and sat down, saying that he was jerked himself. He continued to work intermittently for about a week, and was thereafter totally incapacitated until August 10th, but he has now completely recovered. The Sheriff found that the cause of Coe's incapacity for work was cardiac breakdown, due to the fact that the work in which he was engaged was too heavy for him; that the incapacity was not caused by accident within the meaning of the Act, and that the appellant was therefore not entitled to compensation. On appeal to the Court of Session, the Division affirmed the Sheriff's decision, and found Coe liable in expenses.

The Lord President said the question put to them was whether the injury to the workman was an accident within the meaning of the Workmen's Compensation Act. He confessed that he found the case one of great delicacy and difficulty. Where so many had failed, he was not going to try and define what an accident was. But he could say without fear of being wrong that accident connoted something different from disease. Where what had gone wrong with a man had had its origin in something which happened during his work, it became difficult to say in certain cases whether there had been an accident

or not. Cases at both ends of the line were very easy. A broken leg or scarlet fever would be very easy to judge, the one the one way and the other the other. But with cases just about where the line might be it became a matter of great difficulty. His lordship came to the conclusion, though not without hesitation, that as the sheriff had the advantage of a medical assessor, and had the assessor's views upon what was the matter, that it was not for the court to interfere with the judgement on what was primarily a question of fact. It might be very truly said that there was not much difference between straining the muscles of a man's back and straining the heart, which after all was just a big vessel. But, on the other hand, the view which the doctor had taken was simply that the man was overtaxed by over-exertion. Upon the best consideration, his lordship had come to think that the only thing they could do was to adhere to the judgement of the sheriff.

Lord Kinnear and Lord Pearson concurred.

ILLEGAL CREMATION.

At the Lambeth Police Court on January 18th Ada Emma Webb, of Westmoreland Road, Camberwell, was summoned for having on December 29th last unlawfully and knowingly carried out, procured, and taken part in the burning of certain human remains—to wit, the remains of a certain child—except in accordance with the regulations and provisions of the Cremation Act, 1902. According to a report of the case published in the *Morning Advertiser* of January 19th, Florence E. Rogers, a barmaid, stated that in December last she was expecting her confinement, and the child was unexpectedly born dead about 2 o'clock on the morning of December 29th. She said nothing about the matter, and at her request Miss Kirby, another barmaid, the same afternoon took the body of the child, wrapped in a nightdress and some brown paper, to Mrs. Webb. That was the last the witness saw of the body. Grace Kirby said she took the body of the child and half a sovereign to Mrs. Webb's house. Mrs. Webb said she had no idea of Miss Rogers's condition, and that she was a wicked girl. The defendant and the witness went to an undertaker named Simpson, taking the body with them. The undertaker said that he could not possibly take the body without a doctor's certificate. Mrs. Webb and her witness then returned to Mrs. Webb's house, and the witness then left her, leaving the body behind. Mrs. Webb said she would get rid of it the same night. Detective-Inspector Hawkins stated that on January 11th, accompanied by Detective-Sergeant Hedges, he called upon Mrs. Webb, and said to her that he was inquiring what had become of the body of a baby brought to her by Kirby on December 29th. The defendant replied that Kirby brought the baby to her house; she took it to the undertaker, but he would not bury it because she had not got a doctor's certificate; Kirby left half a sovereign with her, and she burnt the body in her kitchen stove. Addressing the Court for the defence, Mr. Robinson questioned whether there had been an offence under the Cremation Act of 1902, which, he suggested, related entirely to burnings in crematoria. He submitted that, although the defendant acted foolishly, she was a person deserving of sympathy rather than of censure. Mr. Hopkins, the magistrate, said he did not see how he could possibly hold that the defendant did not come within the terms of the section under which the proceedings were taken. At the suggestion of the magistrate the defendant (who was stated by Inspector Hawkins to be a most respectable woman) went into the witness-box. She said she did not know that Rogers was expecting to be confined, and the first she heard of the matter was when the body was brought to her house by Kirby. She still had the 10s. which was brought with the body. She made an effort to see Rogers, but failed. Mr. Robinson thought it was perfectly clear that the defendant did not do this for profit. Mr. Hopkins remarked that when the papers in this case were put before him he thought that it seemed hard that the defendant should be made the scapegoat for the offence of others, but at the same time one saw that she had not the strength of mind to throw off the responsibility which they put upon her shoulders. The defendant took upon herself the responsibility of dealing with the body of a child of the history of whose birth she knew nothing, and brought herself within the section of the Act. She would have to pay a penalty of £10, and 2s. costs. The magistrate expressed his willingness to allow the defendant a fortnight in which to find the money.

CONVICTION OF UNQUALIFIED DENTISTS.

At the Rhyl Police Court, on January 12th, a summons was heard against Edward Hanlon, of Rhyl, who was charged on the information of David Hugh Jones, M.D.S., of the same town, with the offence that he, not being registered under the Dentists Act, 1878, and not being a legally qualified practitioner, unlawfully used an addition or description implying that he was specially qualified to practise dentistry. Mr. Joseph Lloyd appeared for the informant, and stated that the action was supported by the local dentists and by the London and Counties Medical Protection Society. In evidence, and produced circulars which defendant had printed and caused to be registered. For the defence Mr. W. Russell (Messrs. Russell and Russell, solicitors, Bolton) appeared. No evidence was called. The defendant was fined 10s. and costs.

At the same court A. George, of 16, Water Street, Rhyl, and Thomas Thurgood, of Wellington Road, Rhyl, pleaded guilty to similar charges, and they were mulcted in the same fine and costs.

A COMPANY AS DENTIST.

On January 23rd Mr. Justice Swinfen Eady heard the action of Attorney-General against George Smith, which was brought at the instance of the British Dental Association for alleged breaches of the Dentist Act, 1878.

Mr. William K. C. and Mr. A. W. Turner appeared for the plaintiff; the defendants were not represented.

It appears that the company had been formed in 1906 to carry on the business of George C. Smith, whose name had been struck off the *Dentists Register* in 1906. Since that date several convictions had been secured against him under Section 3 of the Act, for practising without a qualification. It was alleged that the company was unlawfully carrying on the business of dentists at several places in London and the neighbourhood. They employed the defendant, George C. Smith, and other persons not being registered dentists or legally qualified medical practitioners to carry on the practice. The question for decision was whether the company was a person within the meaning of Section 3 of the Dentists Act 1878, and the plaintiffs relied upon the case of *Pharmaceutical Society v. London and Provincial Supply Association*. They also referred to the case of the *King v. the Registrar of Joint Stock Companies*, a case decided by the Irish Courts in 1904, where it was held that "dentists" meant "registered dentist," and that, as a company could not be registered under the Companies Act, it could not be registered as a dentist. They also referred to the Irish case of *Attorney-General v. Myddleton's Limited*, where it was decided in 1907 that a company may be restrained from using the word "dentists" in such a way as to amount to a false representation, leading the public to believe that the persons it employed were qualified dentists. Mr. Justice Swinfen Eady granted a perpetual injunction and ordered the company to pay the costs.

The Services.

TERRITORIAL FORCE.

PROMOTIONS OF REGIMENTAL MEDICAL OFFICERS.

It is notified from the War Office that promotions of Regimental Medical Officers of the Territorial Force are governed by the same conditions as those which apply to officers of the Royal Army Medical Corps (Territorial Force). In both cases recommendations for promotion should be submitted when such officers have completed the necessary period of service, and are otherwise qualified for promotion. When a vacancy occurs in the command of a medical unit, recommendations as to the manner in which it should be filled will be similarly submitted.

THE EAST SURREY BEARER COMPANY.

The annual dinner of the East Surrey Bearer Company, R.A.M.C. (Volts), now the 3rd Home Counties Field Ambulance, of the Territorial Force, took place on January 23rd at Kingston, Lieutenant-Colonel J. J. de Zouche Marshall being in the chair. The guest of the evening was Lieutenant-General Sir E. R. Elles, Chairman of the Surrey County Territorial Association, and among the officers present were Lieutenant-Major E. O. Wright, R.A.M.C., and J. Harper; Surgeon-Major T. H. Dickson; Majors E. St. Vincent Ryan and H. Beale Collins; and Captains L. N. Lloyd, R.A.M.C., R.A.M.C. G., R. Edsell, M.D., and E. Canny Ryall; and Lieutenants A. J. Preston, A. S. Coad, R. L. Nares, and G. L. Edsell. About seventy of the rank and file of the corps also attended the dinner. When proposing a toast to the guests Colonel Marshall mentioned that he wanted the clergy and doctors of Surbiton to remember that the Home Counties Field Ambulance was a distinctly educational corps, and that all its members received most valuable training in first aid and in the subjects taught by the Army Medical Corps.

AFTER the first international congress on accidents to workmen held at Liège in 1905 the Permanent International Congress chose Rome as the place where the second congress should be held. The congress will open on May 23rd of this present year. The following are the principal questions on the programme: (1) The organization of medical services for the observations and treatment of the consequences of accidents to workmen. (2) The organization of a medico-legal service to deal with cases of accidents and the establishment of definite criteria whereon the reports of experts shall be based. (3) The diagnosis and prognosis of post-traumatic nervous affections. (4) The estimation of the working capacity of the workman before and after the accident—(a) method of investigating fitness for work; (b) the importance of the condition before the accident; (c) anthropological and sociological criteria; (d) the influence of the varying circumstances on the accident. (5) The influence of the mode of compensation on the evolution of post-traumatic nervous diseases. (6) Statistical data from the medical point of view, since the application of the law as to compensation. The General Secretary of the Congress is Dr. Bandone, Medical Lieutenant-General in the Italian army, and Chief Military Inspector of Health, 38, via Borgognona, Rome.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

The following degrees were conferred on January 16th :

M.C.—R. Davies-Colley, Emm.
B.Sc.—A. E. Stansfeld, Joh. ; F. J. Cleminson, Govt. and Cai. ; R. F. Priestley, Govt. and Cai. ; B. Hughes, H. Selw.

The following have passed the examination in Tropical Medicine and Hygiene :

H. C. Brown, J. Dorgan, H. R. Dutton, L. T. R. Hutchinson, J. M. O'Brien, A. G. Payne, P. L. Stallard, H. E. Stanger-Leathes.

UNIVERSITY COLLEGE, LONDON.

LECTURES ON NATIONAL EUGENICS.

A COURSE of eight lectures on National Eugenics, in connexion with the Galton Laboratory, will be given at University College on Tuesdays at 5 o'clock beginning on February 23rd. The first lecture will be given by Professor Karl Pearson on "The Purpose of the Science of Eugenics." On the four following Tuesdays the lectures will be given by Mr. D. Heron, and will deal with the following subjects : Methods of Eugenic Inquiry ; Transmission of Physical Characters in Man ; Transmission of Psychological Characters in Man ; Inheritance of Disease and Deformity. The course will be continued in the third term, beginning on May 4th, when Miss E. Elerton will lecture on "Effects of Kinship in Marriage" and "Comparison of Heredity and Environmental Factors." Full particulars of the lectures can be obtained from the Secretary of University College.

CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examinations indicated :

FIRST EXAMINATION.—H. L. Batra, K. Bhushan, E. W. Marsh, A. F. Henriques, P. A. Dasgupta, B. G. Shiroodkar, A. I. Luke, M. M. Datta, J. K. Sharma, D. B. Gajdar, E. D. Shroff, N. B. Mehla, K. Nath, N. S. Williams, S. N. S. Aiyangar, T. Sebastian, W. Elder, J. Hegarty, H. W. Ward, V. T. W. Eagles, F. Chand, W. A. Reardon, W. A. Rees, H. W. M. Wallace, C. M. Willmott, E. P. Ghose, J. W. Craig, F. F. Kervalla, W. P. Over, P. C. Banerjee, and A. S. Douglas.

SECOND EXAMINATION.—E. Thorp, T. E. Ferguson, J. M. Christie, J. M. Dalzell, P. W. Grant, W. J. H. Davies, Z. A. de Cruz, E. C. Hamilton, D. A. Evans, N. P. Vaid, and J. Adams.

THIRD EXAMINATION.—B. J. Hatfield, H. V. A. Gatchell, W. Whitfield, W. T. Henderson, H. L. Batra, E. W. Wilbourne, G. B. Moon, Emma M. Johnstone, D. Hickey, K. Bhushan, E. W. Marsh, A. F. Henriques, and A. I. Luke.

FINAL EXAMINATION.—H. D. Dadyseth, F. J. de Souza, W. F. Mitchell, T. M. Jamieson, A. G. Curphy, J. B. Kelso, W. P. Boist, G. N. Braham, Kathleen Reid, Hilda L. Keane, T. J. Vaughan, G. F. Forde, H. A. Higginson, H. W. Turner, A. O'Flaherty, B. M. Tenby, E. Gibson, E. C. Wilford, J. E. Brown, A. M. Shah, G. V. Bhatavdekar, H. R. Gogte, A. Davidson, K. S. Commissariatwalla, T. B. McKendrick, F. H. Kiddle, D. S. Sardesai, P. Stewart, H. S. Harling, J. Aiken, and E. J. Lumsden.

CONJOINT BOARD IN IRELAND.

The following candidates have been approved at the examinations indicated :

FIRST PROFESSIONAL.—M. J. Aherne, A. T. Cannon, T. F. Collins, H. J. Cotter, C. J. Hegarty, C. Hennessy, C. F. D. Kelly, F. McLeahy, A. Verling.

SECOND PROFESSIONAL.—T. F. O'Donnell, J. H. Barry, P. W. Black, P. Daly, J. M. Gilmor, C. J. Halpin, A. Hamilton, C. W. Joyce, C. J. Lonsdale, A. G. McIlwaine, D. McDavitt, A. J. Neilan, P. J. O'Connell, D. P. H. Pearson, F. Phelan, C. Roche, P. R. Todd, A. Wiley, F. Webster.

* With honours.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have been approved at the examinations indicated :

Surgery.—*G. K. Aubrey, *J. Bramley-Moore, *J. B. Tackaberry, H. B. Waller, *H. V. White.
Medicine.—H. W. B. Deaneher, *J. J. S. Rowe, *J. B. Tackaberry.
Forensic Medicine.—J. B. Tackaberry.
Midwifery.—H. S. Brown, A. C. Jenkins, B. A. Keate, J. B. Tackaberry.

* Section I.

† Section II.

The diploma of the Society has been granted to Messrs. G. K. Aubrey, J. J. S. Rowe, J. B. Tackaberry, H. B. Waller, and H. V. White.

It is announced that an International Antivivisection and Animal Protection Congress will be opened in London on July 6th. In connexion with the congress there will be an exhibition at the Caxton Hall of appliances for making the transport and slaughter of animals humane, and of clothing materials which have been obtained without any cruelty to animals.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL

CHANGE OF ADDRESS.

The offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL have been removed to 429, Strand.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

H. B. wishes to know of a school or tutor in France where a boy of 10, whom he wishes to send up to Osborne, may receive a good English education, and at the same time learn to speak French fluently. H. B. would like to hear from a parent who has had personal experience of such a place, and who can vouch for the sanitation of the house and locality.

TREATMENT OF BRONCHIAL ASTHMA.

A MEDICAL MAN who has suffered from bronchial asthma for many years, has been able by care in diet and his mode of living to attend to his practice, but during the last six months has been much worse. He asks for advice, but adds that he cannot take potassium iodide.

ANSWERS.

AJAX.—Country members of the Association may have letters sent to the office of the British Medical Association, 429, Strand, London, W.C. Letters will also be forwarded on request.

LETTERS, NOTES, ETC.

CANCER OF THE TONGUE.

DR. A. S. MORTON (Putney, S.W.) writes: I have read with very great interest the article on cancer of the tongue by Mr. Butlin. The statistics seem evidently to have been prepared with great care, but there appears to me to be one great source of fallacy, and that is the diagnosis, for if the diagnosis is wrong the entire statistical results must be wrong also. Many years ago a case of cancer of the tongue was seen by me; it was treated in the orthodox manner of the period, such as various local measures, antisyphilitic and other constitutional remedies, removal of a tooth, avoidance of tobacco, and so forth; finally, the man was seen by Sir James Paget, who pronounced the case cancer of the tongue, and advised removal of the organ. The man was afterwards seen by Mr. Edward Cock, of Guy's, who said it was not cancer at all; he advised a certain line of treatment, which was useless; and finally the patient disappeared from observation. Some considerable time afterwards I met the man in the street. He then said he was quite well, and the tongue appeared to be healed perfectly, due to the skill of some old woman. Now, if this tongue had been removed, either with the entire glands or otherwise, it would have gone to swell the percentage of successful operations. Regarding microscopic diagnosis, some time ago, at a post-graduate course of lectures, Sir Jonathan Hutchinson said, "I do not wish to decry the use of the microscope as an aid to diagnosis in cancer, but do not rely upon it entirely." He then proceeded to relate a case in which the subsequent results proved it to be one of cancer, although the histologist had pronounced it to be benign. I do not pretend to be one of the "scientific" and "academic" brigade of the Royal College of Surgeons, but I could multiply such cases as the above, and I have no doubt that many of the despised and ignorant members of our College could do likewise. I can also state that I have seen many cases of cancer of various organs where the patients had declined all surgical interference, and yet they managed to live for a great number of years. It would be very interesting if some statistics could be prepared showing how many years such patients do live after diagnosis and refusal of operation, and in some way to compare these cases with those who have suffered the operation to be performed.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under
Each additional line
A whole column
A page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at Postes Restantes addressed either in initials or numbers.

A Lecture

ON

RADIUM IN SURGERY.

DELIVERED AT THE LONDON HOSPITAL, JANUARY 26TH, 1909.

BY

SIR FREDERICK TREVES, BART., G.C.V.O.,
C.B., LL.D.,SERJEANT-SURGEON TO H.M. THE KING; SURGEON IN ORDINARY TO
H.R.H. THE PRINCE OF WALES; CONSULTING SURGEON TO
THE LONDON HOSPITAL.

SPECIALLY REPORTED FOR THE "BRITISH MEDICAL JOURNAL."

MR. HOLLAND, MR. FENWICK, AND GENTLEMEN,—It has appeared to me, as it has appeared to many, that there is the possibility of a great future for radium in the domain of surgical therapeutics. I say *possibly*, because radium is a new remedy, and one must exercise the very greatest caution in speaking of the potentialities of a new remedy. A new remedy is a thing of great expectations and of very ready promises, but sooner or later it must be inevitably associated with a measure of disappointment. I need not remind you of the expectations which were aroused on the introduction of the x rays; they were to revolutionize surgery. Well, they have not done so. But the x rays have accomplished a marvellous work. And yet it is not perhaps unsafe to say that we are within sight of that point where the limitations of the x rays in treatment will be found. The same applies to the high frequency current. That measure was to cure practically every human ill; yet I think I am right in saying that the expectations formed of it have not been realized, and that those who hoped so much from it may feel that they are to a certain extent in the position of false prophets. So also with the Finsen light. There never was a more splendid enterprise in hospital administration than the introduction of the Finsen light into this hospital. The good it has done it is impossible to express in ordinary language; but yet, I imagine, we are not very far from reaching the actual limit of the good that is to be effected by that measure. On the present occasion I have not to preach to you any new doctrine. I merely wish to place before you a *provis* of the present position of this subject of radium in surgery, and to state the facts which seem to justify us in supposing that the utility of radium is likely to be great. I will first of all, if you please, speak of the maladies that radium can cure, then of the method in which radium acts, and, lastly, of the lines upon which the investigation of its powers is likely to proceed. First of all with regard to the cases which radium can cure. In this connexion I do not propose to deal with published cases, although the literature of the subject is large enough; I propose only to speak of patients whom I have actually seen and personally examined. The majority of these were seen in the Paris Institute, and I should like to say how deeply obliged I am to Dr. Louis Wickham, the Director of the Institute, for his courtesy and kindness in allowing me to see the work of that institution.

Let us deal first of all with angioma, using the term in its widest sense. It may be said, and I think without hesitation, that radium will cure every form of naevus. It can cure the "port-wine" stain, and I would ask surgeons at the present day what measure they have available of which they can say the same. It can rid the patient of a pigmented mole, of a hairy mole—two troubles practically incurable if the size be beyond certain limits. In connexion more definitely with naevus, let me take four illustrative cases. One is that of an infant with a naevus on the crown of the head the size of a gooseberry. There is no means of dealing with such a growth except by operation. It was cured by a comparatively short application of radium. Here is another case, a little more striking—a girl with an angioma of the eyelid the size of a plum. This had been subjected to four operations; twice it had been excised, twice it had been treated with the actual cautery, but with no benefit. It was perfectly cured by radium without trouble or discomfort to the individual. Perhaps a more striking case is that of a young woman who had a naevus occupying nearly the whole of one

side of the face. She had been subjected to innumerable operations, but with only very imperfect success, I should almost say with no success. But under the influence of radium—and the treatment was, of course, long extended—she was cured. The last case I will trouble you with under this head is also remarkable. It was that of a child of 12 with a fibrous angioma situated in the substance of its arm, free from the skin, which was uncoloured and sound. The mass was of the size of a hen's egg. It was treated with radium from two sides, and was entirely dispersed in four weeks. It is, I am bound to confess, a little astonishing that a solid mass of such magnitude, not a mere subcutaneous growth, should have vanished so readily. I may here remark that it seems possible to say of radium that there is a relation evident between the amount of radium used and the good it can accomplish. Until now, considering the little quantity of radium available, it means that we are dealing with a substance which may be regarded as limitless. You cannot say that of x rays, of the high-frequency current, or of the Finsen light, for they, at least, seem to have reached the limit of their powers. It would not, perhaps, be unsound to draw the conclusion from that that if you could have radium enough you could carry out surgical measures far beyond the confines to which radium is at present restricted. With regard to skin affections, you probably know well enough the effect of radium in curing chronic local eczemas, and especially forms of eczema associated with itching. Nothing is more curious in the use of radium than the manner in which it immediately cures, and apparently permanently cures, itching when placed over the surface on a piece of varnished silk. Then radium can cause keloid to vanish; the keloid left by a wound, the keloid left by tuberculous glands, and that obstinate form known as the acne keloid. For instance, I saw in Paris a man, about 30 years of age, the nape of whose neck had been in an appalling condition from acne keloid; apart from the disfigurement produced, the incessant distress made his life almost unbearable. This man had subjected himself to many forms of treatment, but with practically no result. Under the influence of radium the condition had disappeared, and the skin had become almost normal in appearance. I will say nothing about vanishing glands in certain cases where radium has been used, because that may be quite accidental, and it would be premature to draw conclusions from the occurrence.

Now we come to rodent ulcer. Radium will cure rodent ulcers. Of what grade? Rodent ulcers which have existed for many years, in which the tissues have become adherent to the bone, or apparently to the bone, in which there is ulceration, and in which—and this is the most important point of all—in which the Finsen light, the x rays and cataphoresis have all been tried and have all failed.

Such cases—and there are many of them—may be cured by two sittings of radium lasting one hour each, the parts being finally left free from attachment to the deeper parts, the skin being soft and pliable. Why I lay stress on such cases as this is for this reason: it has been said radium only acts by means of the x rays, which are part of its radiation. Anyhow, here are cases, numerous enough, in which a condition is cured which has refused to heal after persistent treatment by x rays. In other words, radium can effect a cure where x rays cannot.

With regard to epithelioma of the tongue and epithelioma of the lip. They are cured by radium. You say of what degrees? I acknowledge that the cases are in the early stages of epithelioma; but they are epitheliomata that are ulcerating, and that, so far as we know, can yield to no other treatment except that of operation. If, therefore, an epithelioma of the tongue can be cured by radium, and cured to the satisfaction of those who are responsible for the case, it is a case of epithelioma treated without operation. Many of these I have seen. And you will notice in the present issue of the *BRITISH MEDICAL JOURNAL* a paper showing the treatment carried out by Dr. Dominici, in which it will be evident to you that epitheliomata of some degree, and one might say almost extensive epitheliomata, have been treated with a measure of success. The same remark applies to commencing epitheliomata on the inside of the mouth. With

regard to epithelioma of the face, I can speak of these cases seen in the Paris Institute. An epithelioma of the face which had perforated into the nasal passage; that was cured after a good many sittings. An epithelioma of the ala nasi, which was destroyed under the influence of radium after sittings which amounted in all to eight hours. An epithelioma of the cheek the size of a two shilling piece cured and the surface healed over.

You may ask, But are these results permanent? They apparently are. It is true that no great amount of time has yet elapsed; but I saw one case in Paris where an epithelioma of the face cured by radium was perfectly sound at the end of two years. We await with interest the extension of this measure of treatment to malignant disease of the uterus and rectum.

Now, with regard to the action of radium. Radium is obtained from pitchblende, a compound of uranium, and I show you specimens of it obtained from Joachimsthal. In appearance, while it is not unlike pitch, it is a little more like anthracite coal. Here is a piece of pitchblende with a little of the rock with it. Here is a seam of pitchblende as it runs in the igneous rock in which it is found. Here, again, is a specimen of pure uranium. Uranium plays a very large part in the manufacture of radium. Radium has, as you know, never been isolated; what we speak of as radium is the sulphate, the carbonate, or the bromide of radium. It appears as a whitish powder, and that powder becomes later on a little yellow, and then perhaps a faint brown. There is radium in this glass tube, and it has turned the glass violet, because it is soda glass. If this had been potash glass it would have turned it brown. On exposure of the glass to heat the colour vanishes. At present the commercial value of radium is artificially very high. If radium ever sank to such a degree of cheapness that it was worth its weight in mere gold it would be exceedingly cheap.

You know, of course, that radium gives off heat, that it is phosphorescent, that if it is dissolved in water it decomposes the same into its component parts; but the main property is that it is radio-active. Radio-activity means that the rays given off by radium have the power of penetrating solid and opaque substances, the power of affecting a photographic plate, the power of producing fluorescence, and the power of rendering air or other gas a conductor of electricity. These rays are of three kinds, known as the alpha, beta, and gamma rays. The alpha rays and the beta rays are composed of material particles or ions, which carry a charge of electricity. That they are material is shown by the fact that the power of these rays is lost when they are passed through cotton-wool. The alpha rays are composed of ions of fair size, having a mass equal to that of an atom of hydrogen. They carry a charge of positive electricity, they are deflected only by an intense magnetic field, they have little penetrating power, and a relatively slow velocity. The beta rays, on the other hand, are composed of ions of smaller size, having a mass equal to only $\frac{1}{1836}$ part of that of an atom of hydrogen. They carry a charge of negative electricity, are easily deflected by a magnetic field, have great penetrating power, and move with a very high velocity. The gamma rays are of a different type. They contain no ions; they carry no electric charge; they are consequently not deflected by a magnetic field; they have enormous penetrating power, and their velocity is about the velocity of light, with which they are comparable. When I tell you that in surgery some of these rays do harm and others do good, you will see how desirable it is to have some acquaintance with the three types of rays.

With regard to general qualities, the alpha rays may exist alone. For instance, polonium, a radio-active substance discovered by Madame Curie, and named after her own country, contains only alpha rays. Alpha and beta rays are absolutely distinct and independent; they can exist the one without the other. But the beta rays and the gamma rays are inseparable, they are never found dissociated. The alpha rays are supposed to give off the heat, and they burn. They are capable of producing a very troublesome ulcer of the skin. They have greater ionizing power than the beta rays, probably as 100 to 1. The penetrating power of these three kinds of rays is expressed as follows: Taking the penetration of the alpha rays as 1, they are stopped by a sheet of mica. The beta rays have a penetrating power of 100, and will pass

through a centimetre of lead. The penetration of the gamma rays, on the same basis, would be represented by 10,000, and will pass through one inch of steel. The alpha, beta, and gamma rays have a very close resemblance to the rays which are met with in the vacuum tube used in the production of the x rays. I had this vacuum tube brought here for this purpose. When the current is running through the tube the "cathode rays" pass from the cathode or negative pole to the anode or positive pole.

They correspond to the beta rays of radium. If you take the five qualities of the beta rays as above given, those same qualities are found in the cathode rays. They carry ions which have a mass about equal to the thousandth part of that of an atom of hydrogen, they carry a charge of negative electricity, they are deflected easily by a magnetic field, they have great penetrating power, and their velocity is very high. The x rays are dependent upon the cathode rays, and are inseparable from them in the same sense that the gamma rays are inseparable from the beta rays. Where are the equivalents to the alpha rays in this vacuum tube? If holes are made in the cathode, streams of light pass back in the opposite direction. These are called the "canal rays," or the "diacathode rays." And their qualities are the same as those already given as characteristic of the alpha rays.

The next question is with regard to the application of radium in treatment. The main feature in the application of radium is surface. It is ridiculous to attempt to apply radium as a broken up bead in a glass tube without any notion of the amount of alpha and beta and gamma rays you are using or how far the radiation extends. In applying radium surgically you want surface. In other words, a little radium spread over an even surface is much more powerful and can be much more exactly used than a bead of it in a glass tube. The power of any prepared plate of radium can be estimated by the electrometer with precision. Here are three specimens of the type of apparatus as now used in the Radium Institute in Paris. They are adapted for various localities and are of varying radio-activity.

The strength, by the way, of radium is estimated by taking uranium as a unit. Radium is then represented by a radio-activity of 2,000,000; a piece of "quarter-strength" will therefore have a radio-activity of 500,000. The powdered radium, when placed on the disc or plate, is covered with a varnish, which is unaffected by boiling, by alcohol, or by the heat of a sterilizer. In this specimen are only 10 mg, but every milligram is available. Put the same quantity into a glass tube, and the agent is almost useless. Radium can be mounted on "gum elastic," as in the uterine stems employed, or it can be spread on silk or cloth, or on anything which can be varnished.

Radium must be ordered by a definite prescription. For the individual case a plate of a certain diameter is ordered, and the proportion of alpha, beta, and gamma rays required will be stated in the prescription. The alpha rays may have to be cut off. How? By a certain thickness of aluminium, a very thin plate. Then comes the question of the distance; how close should the plate be held? The closer it is held the more intense is the effect, but the narrower the area of action. How long shall it be applied? Radium of this type I now show can be applied for about an hour at a time. Dr. Dominici, has made special use of the ultra-gamma rays, the most penetrating rays of all, and allows them to act for hours at a time. This limited action is secured by so screening the plates that what passes through into the patient's body are only the ultra-gamma rays, those of the most intense velocity and the greatest penetrating power. There is a still more curious thing with regard to radium. Suppose this to be a closed glass vessel in which you have suspended a tube containing a solution of radium, or a salt of radium. If you put into that vessel a penny, that penny becomes radio-active. This is not due to the rays coming through the glass of the tube. Screen the tube with any thickness of lead you like, and it will make no difference, the penny will still become radio-active. This induced radio-activity is due to something which comes out of the tube, and that something is the "emanation." If you break the glass globe with which the experiment is made you find every bit of it is radio active. Take the penny out and it is radio-active and

remains so for a considerable time. Scrub the penny with emery powder, and it loses its radio-activity. Test the emery powder used, and behold it has become radio-active. Wash the penny with nitric acid and it loses its radio-activity; evaporate the nitric acid and the residue left is radio-active. In brief, there comes off from radium an emanation, or if you like a vapour, which has the power of rendering any body it touches radio-active. There is no method of inducing radio-activity except by the emanation, and it is evident that this emanation leaves on any surface it touches an active deposit—a deposit which you can take off and remove.

It is probable that much of the future of radium as regards surgery lies with the emanation. This active deposit forms on any surface exposed to the emanation. By increasing the surface so exposed you increase the amount of radio-activity.

As I have been very careful not to mention any fact other than what I have myself seen, I wish to state the following as a thing told me: An eminent scientist in London has used a solution of this active deposit as an injection into the tissues of the body, for it is easy to get a solution of that deposit. This solution was injected into a mouse which was the subject of an abdominal cancer produced artificially, and the growth vanished. It is scarcely fair to mention this case, because I can add no further details. Such an experiment needs to be verified and supplemented by many other data. I have noted the local effects of subcutaneous injections of the solution of the emanation in the human subject. I will not give you details of the case, because the issues are misleading, and open up a wide subject into which I need not now go. Each injection performed in this patient with an ordinary hypodermic syringe produced a scar and pigmentation of the skin such as I have never met with in my whole surgical experience. The appearance at the site of each puncture was entirely new to me, and led me to think that I was viewing a condition of scar which had hitherto been unknown.

I will now conclude by pointing out the lines upon which the future investigation of this subject will probably extend. First of all, it is very essential to ascertain the action of the radium rays and of the emanation upon bacteria and their products. In the next place, the selective action of the radium on certain tissues must be studied. This selective action is one of the most astonishing things about radium as illustrated by the manner in which it picks out vascular tissue for destruction. Under its influence this tissue, as met with in the angina, vanishes. What is radium likely to do for other conditions associated with vascular growth? What is it likely to do for Graves's disease? Has it any kind of selective effect upon embryonic tissue, which is allied to that of certain growths? All that has yet to be ascertained. Then comes the effect of radium in large amount. On this question of the amount great possibilities appear to hang. Little has yet been done, except by Dr. Dominici, to ascertain the effect of introducing radium into the substance of a growth in a tube permeable to its rays, such as a tube of thin aluminium. So far as he has investigated the matter the results have been encouraging.

Then come the questions of the effect of the emanation if inhaled, the effect of injection into the diseased parts of a solution of the emanation, the utility (if any) of radio-active water and other substances rendered potent by radium.

Finally, let me once more warn you against raising false hopes in discussing the potentialities of a little-known remedy.

A PETITION promoted by the Betterment of London Association to the Prime Minister requesting early legislation to check unnecessary and objectionable street noises has been signed by a large number of medical men residing in the West End of London.

THE second international course of legal psychology and psychiatry will be held at Giessen, April 15th to 18th, 1909. The course will be under the direction of Professor Sommer, who will have the co-operation of Professors Mittermaier and Dannemann of Giessen, and Professor Aschaffenburg of Cologne. All communications on the subject should be addressed to Professor Dr. Sommer, University of Giessen.

Observations

ON

HUMAN GLANDERS:

WITH A STUDY OF SIX CASES AND A DISCUSSION OF THE METHODS OF DIAGNOSIS.

BY

JULIUS M. BERNSTEIN, M.B.LOND., M.R.C.P.
D.P.H.Camb.

CREATOR OF THE MUSEUM AND ASSISTANT PATHOLOGIST TO THE WESTMINSTER HOSPITAL, AND LECTURER ON BACTERIOLOGY AT THE MEDICAL SCHOOL,

AND

E. ROCK CARLING, M.B.LOND., B.S., F.R.C.S.,

ASSISTANT SURGEON TO THE WESTMINSTER HOSPITAL, AND ASSISTANT SURGEON TO THE SEAMEN'S HOSPITAL, GREENWICH.

WITHIN the last few years five cases of glanders have been admitted to the wards of the Westminster Hospital. The disease, in its different types and stages, presents such diverse clinical pictures, and diagnosis is so often difficult, that there is warrant for recording these cases at some length.

This article was almost complete in 1905, but after making a study of 134 cases reported in the literature, an exhaustive treatise by Robin of Montreal appeared with an analytical report of 156 cases, including most of ours. Hence we did not feel justified in burdening the literature with a repetition of what had been so well done in Robin's thesis, but preferred to await further cases to enable us to investigate several points that had occurred to us. So far no other case has come into our hands, but many have been diagnosed recently in London, and we are firmly convinced that with a better knowledge of the protean symptomatology many will be revealed which otherwise would be overlooked. There can be no doubt that the Registrar-General's statistics, which show glanders as a rare disease, are misleading, and considerably underestimate the incidence of this disease.

CASE I.

H. A. L., aged 25, horsekeeper. Admitted November 12th, 1904, under the care of Mr. Spencer.

On October 31st fell in the stable and hurt his ribs; for this he was strapped. Two days later went to a dentist with an "alveolar abscess"; "cellulitis" developed, and for this he was treated at various places; no incision was made. On November 9th nodules appeared on the limbs, more or less in the neighbourhood of the joints, the knees more especially. Next day, 10th, a pustular eruption broke out on the neck, trunk, and limbs; the buccal mucosa sloughed, and a nasal discharge appeared; the upper part of the face became swollen. On admission temperature 103.4° F.; respirations 38. Restless, low delirium; no expectoration, no diarrhoea. The glandular lesions were of three types: (1) A diffuse, brawny, dark-purplish swelling of the face and neck, (L.) involving the temporal portion of the left conjunctival sac; the advancing edge erythematous. (2) A pustular eruption, distributed without special reference to aspect, upon face, neck, trunk, and limbs; the lesions consisted of a clear yellowish-white matter head upon an angry red areola. Upon the left cheek these pustules ultimately became confluent, and, breaking down, left a large honeycombed, ulcerating surface. (3) Multiple subcutaneous and intramuscular nodules apparently in the course of the lymphatics; these nodules reddened, superficially and broke down; but in no case did the skin actually give way over them. One or two were incised for diagnostic purposes; the pus was thick, yellow, curdy.

Abdomen normal. Splenic dullness increased, but edge impalpable.

Breath sounds altered chiefly in respect of prolonged expiration; there was sign of consolidation; no gross added signs; the sounds might be described as "wheezing."

There was some articular pain, but the joints were not distended. There was no enlargement of the axillary, inguinal, or cervical lymphatic glands. The tongue was not furred, but the mucosa of the cheeks was extensively ulcerated. Mucopurulent discharge from the right nostril. Sensation, general and special, undisturbed.

The temperature kept above the 103° line until a few hours before death, which occurred on November 14th, at 6 a.m.

Thirty-two horses became glandular, and it is worth noting that seven days elapsed after the first appearance of symptoms in the man before a diagnosis of glanders in the horses was made.

Pathological Findings.—Examination of the pus from a superficial abscess during life revealed polymorphonuclear leucocytes, and after prolonged search and careful staining a few typical *B. mallei* and no other organisms (Fig. 6);

some of the pustules, however, had become contaminated with staphylococci. From the deeper abscesses pure cultures were obtained on potato and glycerine-agar of an organism morphologically and culturally resembling *B. mallei* and these inoculated into guinea-pigs gave positive results, though the animals died too rapidly in thirty-six hours to allow of "characteristic" changes suggesting that the organism was of exceptionally high virulence. Typical *B. mallei* were obtained from the bodies of the guinea-pigs.

Post-mortem Appearances.—(Eighteen hours after death).—Body well nourished; great tumefaction of soft tissues of the face, especially of the left cheek and lips—the swelling is partly due to inflammatory oedema and exudation and partly to the presence of abscesses in the skin and muscles; numerous pustules of varying size (pin's head to pea) in the skin of the head, neck, trunk, and extremities (Fig. 1); some stand out, others are flat and depressed, whilst on the left side of the cheek and jaw many have broken down so as to produce a punched-out honey-combed appearance with a dusky purple hue; the muscles are the seat of numerous abscesses containing a thick sanious pus; joints normal; mucosa of nose and adjacent sinuses is much swollen and hyperaemic, that over the inferior turbinated bone resembling an aggregation of small papillomata (Fig. 2). The lungs are much engorged and oedematous and the seat of numerous small nodules with softened centre and hyperaemic periphery; pleurae covered with a thin layer of fibrinous lymph. Spleen, 12 oz., soft and homogeneous. Remaining viscera normal, save for engorgement of kidneys, adrenals, and brain.

Histological Appearances.—The abscesses in the skin, muscles, and lungs consisted of collections of round cells with indefinite nuclei, though some of these were undoubtedly polymorphonuclear cells; for the most part they could not be distinguished from monomorphonuclear cells by any method of staining. The blood vessels, of which some are in the centre of the cell collections, are congested, but it is not clear whether the virus has arrived by the veins or lymphatics. A characteristic feature of all these areas is the extensive central degeneration of a peculiar type, the *chromatolysis* of Unna, resulting in a deeply staining diffuse network of debris which obscures the detail of the sections. In the skin there is an epidermal and subepidermal collection of round cells, amongst which are some swollen and desquamating epithelial cells. In the muscles the cell collections spread along the interfibrillar tissue, and there is much surrounding oedema (see Fig. 3). In the lungs the small areas of consolidation consist of alveoli filled with cell and plasma exudation, and surrounded by a broad zone of hyperaemia in which the alveoli are choked with red blood corpuscles. Examination of the thickened, corrugated and hyperaemic mucosa of the nares showed merely oedema and congestion. There was no evidence of cell infiltration or proliferation, and no organism could be found.

Bacteriological Examination of Sections.—(Careful search, after special staining (carbol-thionin blue after preliminary treatment with acid) revealed sparsely scattered typical beaded bacilli in the lungs, skin and muscle abscesses, but the central degeneration, with its avidity for the same dyes, rendered their identification difficult

(see Fig. 7). It must be stated that, with a modified Romanowski's stain, the bacteria were found just as readily, and the general appearance of the sections was more pleasing.

CASE II.

A. A., aged 45, horsekeeper. Admitted under the care of Mr. Spencer, July 14th, 1905.

Illness commenced seven weeks since with severe frontal headache, pains in the muscles of calf and forearm, and prostration. No history of infection could be obtained, and no initial lesion was discovered. Not till five weeks later did he notice any swellings; then in quick succession painful lumps appeared in the left leg and forearm. He stated that these lumps had to some extent decreased in size; he had no joint pain, no intestinal or respiratory disturbance, no ulceration of or discharge from the nasal or oral mucosae. Temperature, 102.2°.

Upon examination, some eight or ten subcutaneous and intermuscular abscesses were found and incised. All save one were upon the lower segments of the extremities. The urine at first was normal but subsequently became albuminous. Carbolic acid occurred after the first operation, at which pure phenol was applied to the abscess cavities. A few more abscesses formed and were opened. A fortnight after admission the right knee became swollen. It was aspirated, and, as the fluid contained *B. mallei*, subsequently opened and drained. From this time the condition was one of progressive intoxication with asthenia. Severe diarrhoea set in and respiration became embarrassed, though no pulmonary physical signs were detected. The temperature, which hitherto had run an irregular course, varying between normal and 104.8°, took a steady upward trend, and at death was 105.2°.

Pathological Findings.—On the day after admission pus from a cutaneous abscess revealed, after careful search, one or two bacilli only, and no other organisms; but characteristic cultures of *B. mallei* were obtained on glycerine-agar and potato (brownish slimy growth) in forty-eight hours, and these cultures, inoculated into guinea-pigs by Professor Hewlett, produced typical enlargement of the testicles. Fluid from the affected knee-joint, aspirated on August 8th, showed only two bacilli in the centrifuged deposit; but here, again, typical and luxuriant cultures were obtained.

Blood Examination.—On July 21st, when the general condition was fairly good, agglutination experiments were tried with the

serum, even in 1 in 2 dilution, caused no clumping or loss of motility. About this time, also, cultures of the blood were made in large quantities of peptone broth and glycerine-peptone broth with negative results; but on August 10th—the day before death—the blood was again drawn direct from the vein, and in forty hours typical cultures were obtained.

Post-mortem Appearances.—(Four hours after death).—Rigor mortis; body emaciated; numerous surgical incisions in skin and subcutaneous tissues of the extremities; one pustule on the left hand and another on the chest. Blood in the lungs alone showed evidence of secondary infection—the right, 17 oz.; the left, 14 oz.; no pleurisy; scattered throughout the lower lobes and felt superficially were numerous dark, haemorrhagic, firm areas of small size, con-

Fig. 1.—Photograph taken after death of Case I. The honeycombed appearance produced by the broken-down pustules on the cheek and jaw is well shown. Also some small pustules, discretely scattered over the left shoulder, and a few on the right and on the trunk.

Fig. 2.—Wall of nasal cavity of Case I showing papillomatous condition of oedematous and engorged mucosa over inferior turbinated bone.

solidated so that they sank in water; in the centre of some of these areas was a little pus; the intervening lung tissue was apparently normal, as were the bronchi and trachea. Nothing of note in the heart (10 oz.), peritoneum, or abdominal viscera, save for slight congestion of the intestines; spleen (6 oz.), purple colour and firm; kidneys (15 oz.), febrile; brain (45 oz.), arteries and thoracic and abdominal glands all normal. The right knee-joint had been drained, and the cartilages were roughened.

Histological Appearances.—The lesions were similar to those in Case I—namely, inflammatory foci of a haemorrhagic type, but less active. In the lungs were patches of pneumonic consolidation, with much surrounding haemorrhage and great

curdy pus and gelatinous matter. The wound in the arm was sewn up and healed by first intention. In the thigh wound a sinus formed, but closed up rapidly; the superficial parts granulated and healed perfectly under a "lent" bandage.

On January 25th, 1902, there was pain in the left shoulder, which passed off, however, without anything definite developing. The notes state that "about half a dozen raised spots with vesicles are scattered over the left shoulder and neck under the chin." There is no evidence that these had anything to do with the disease. He was discharged well.

Pathological Findings.—From the pus typical cultures were obtained on glycerine-agar plates and subcultures on potato on December 24th, and these inoculated into guinea-pigs by

Fig. 3.—Section of muscular abscess from Case I showing purulent infiltration between the fibrils, congestion of vessels, chromatosis of the infiltrating cells. (Semidiagrammatic drawing by Mr. J. Braxton Hicks.)

congestion of the capillaries. In these areas the central alveoli are filled with leucocytes, and the adjacent ones with leucocytes, blood, and fibrin in varying amount; in some the bronchi are occluded by a proliferative and exudative bronchitis, and in the centre of one is a vessel filled with leucocytes and debris (suppurative bronchitis), an appearance suggesting an infection via the pulmonary artery (Fig. 5). The affected bronchi are near to the inflamed vessels, so the condition may be described as septic bronchopneumonia. *B. mallei* were found in scanty numbers in the lungs in the pneumonic areas, but not in the spleen or kidneys, which showed little change histologically.

Fig. 4.—Patch of haemorrhagic bronchopneumonia. (About natural size.)

CASE III.

H. S., aged 25; horsekeeper. First seen in out-patient department by Dr. Hebb, who recommended him for admission with a tentative diagnosis of glanders.

Syphilis five years ago, but no sign for three years. The present illness began fourteen days ago, when he awoke to find swellings of right arm and leg; he thinks they have not increased in size since. On and off he has had severe nagging pains in both places. There have been no nasal or pulmonary signs or symptoms. The swellings were intramuscular abscesses, that on the arm being discrete, with little or no surrounding induration. The thigh lesion, on the other hand, showed a red area, cancer size, on the front of the thigh about the middle, and a wide area of brawny induration. Temperature on admission (December 18th, 1901) was 99°, rising to 103° at midnight.

Operation, December 23rd.—The swellings incised, contained

Fig. 5.—Section of a patch of pulmonary consolidation of Case II. In the centre is a branch of the pulmonary artery, which is filled with purulent clot; around this are alveoli filled with cell exudate and in a condition of advanced degeneration, while further afield are alveoli engorged with blood corpuscles; to the left and below this artery are a bronchiole and a vein, the former filled with cell exudate the latter with corpuscles. (Semidiagrammatic drawing by Mr. J. Braxton Hicks.)

Mr. Shattock gave positive characteristic reactions, namely, "acute inflammation of tunicae vaginales, adherent testes, and intense engorgement."

On February 6th only *Staphylococcus pyogenes aureus* were cultivated from the wound.

CASE IV.

T. M., aged 26, carpenter, working in a stable where there were sick horses. First saw Mr. Turner in the out-patient department, where a diagnosis of glanders was suggested.

Admitted June 2nd, 1905, under the care of Mr. Stotham. Temperature on admission 101°. There had been general malaise for three weeks; pain and tenderness in lower third of the thigh and peroneal aspect of the right leg came on suddenly eight days ago, and confined him to bed.

At the operation intermuscular abscesses were found; there was no affection of bone or periosteum such as the clinical signs had led one to expect. Both wounds granulated well.

Pathological Findings.—On June 2nd, 1905, a blood examination showed a distinct leucocytosis, but no increase of polymorphonuclear cells. Red corpuscles, 4,920,000; haemoglobin, 55 per cent.; leucocytes, 19,400. On June 2nd in the fresh pus only one or two bacilli were found after long search, but characteristic cultures were obtained on various media, the growth being described as a Gram negative, relatively-thick bacillus, actively motile and non-beaded, and badly staining. Typical inoculation results were obtained in guinea-pigs in three days. Seen again August 4th, 1906. Had no further trouble of any kind; his blood at this date possessed no agglutinating power for the *B. mallei*.

CASE V.

A. B., aged 22, carman. First seen by one of us in the out-patient department in May, 1904.

At that time the disease had existed for nine months. The patient stated that the earliest symptom was deafness, a sense of fullness in both ears; the nose became obstructed, and both nostrils discharged. His speech had become indistinct about a month after the onset of the trouble. When seen, the soft palate was entirely destroyed; the hard palate was perforated, and there was a widespread granular erosion in the oral and nasal pharynx. On the lateral aspect of the dorsum linguae was a soft dysrhex swellng, walnut size. There was no history of evidence elsewhere of acquired or congenital syphilis. The father and mother were healthy, but there was tuberculosis on both sides of the family. The condition was regarded as

syphilitic, an opinion concurred in by Mr. de Santi and most of those who saw the case subsequently. Mercury and iodides were prescribed.

In October, 1904, he was admitted under the care of Mr. Tubby, and remained under treatment at intervals until April, 1905.

On admission, the oral surface of the hard palate, posteriorly, was tuberculated, and bathed in tenacious mucus; the tonsils were ulcerated, and the posterior wall of the pharynx, which had been the seat of extensive shallow ulceration, was now covered with crusts. When these were removed it was seen that many small ulcers had become confluent; the edge was circinate; in some places healing had occurred, with the formation of slightly depressed and puckered cicatrices; here and there yellow points indicated the sites of ulcers in process of formation. The lingual mass had become a large shallow ulcer, with a broad raised edge, pallid at the summit, indurated, and pretty sharply defined.

There was but little tenderness; salivation was marked. The anterior parts of the nose were not ulcerated, and there was no nasal discharge. The cervical glands were moderately enlarged.

The lesions were painted with lactic acid and kept constantly cleansed. In November mercurial injections (biniodide) were commenced; the tongue was several times scraped.

The failure of antisyphilitic remedies was so pronounced that, although no tubercle bacilli were found in the scrapings, light treatment (x rays) and high-frequency applications were tried, but without success. By December, 1904, the ulceration had spread considerably, involving the anterior parts of the tongue, but for a month or two the progress of the disease seemed to be arrested and the patient's general condition improved. The temperature curve for nine weeks showed an almost uniform daily intermission of 2 or 3 degrees, but for the last month or two of his first stay in hospital was almost within normal range.

Readmitted January 14th, 1905. The temperature having been practically normal for 48 hours, mallein n°xvi was injected

Mallein reaction, Case v.

→→→ Injection of mallein, n°xvi. →→→ Injection of mallein, n°xvi.

and a definite reaction resulted. A second injection on the 17th produced a similar but less marked result. On the 26th an injection of tuberculin was given; there was no local reaction, and though on the 28th, 29th, and 30th there was some elevation of temperature there was nothing like a typical pyrexia.

Admitted for the third time, April, 1905. The disease had spread extensively, having destroyed the alveolar parts of the upper jaw anteriorly and to the left posteriorly. Almost the whole of the anterior third of the tongue was destroyed; the right antrum of Highmore was invaded.

Hypodermic injections of calomel were employed, thirteen doses of 5 grains each being given in six days, but without benefit.

By the courtesy of the medical superintendent of the Lambeth Infirmary, Dr. Quarry, we have learnt that death took place from "exhaustion" on August 19th, 1905. The lungs were clear; there was no generalized eruption, but he had had abscesses about the buttock, and at death there was a gangrenous patch on the palmar surface of the right hand. The lower jaw was extensively necrosed; there was ulceration of the nasal passages, with inflammation of the conjunctiva and lacrimal sac on the left side. The central two-thirds of the tongue had sloughed.

Pathological Findings.—A portion of the spreading edge of the ulcer was examined histologically several times during his stay in hospital. The tissue, consisting of mucosa and submucosa, showed the appearances of intense inflammation with superficial ulceration and subjacent inflammatory exudation and oedema; superficially there were fungi and bacteria of various kinds, but none characteristic; no tubercle bacilli could be found on special examination. A diagnosis was ultimately arrived at by inoculating a piece of the ulcer into a guinea-pig, subcutaneously, and obtaining a positive Strauss reaction. A more recent examination in the light of the diagnosis is of interest; a few beaded bacilli, sometimes in clumps, resembling *B. mallei*, can be found in the deeper parts amongst the cell collection, and no other organisms but these in the depths. The

cells are of all kinds, leucocytes and connective tissue cells, with numerous blood vessels scattered amongst them. A striking feature is the presence of comparatively large areas of cell degeneration (chromatolysis) with a marked affinity for blue dyes. No giant cells were seen. The tissue is for the most part of the nature of granulation tissue.

CASE VI.

(Under the care of Mr. C. C. Choyce, Assistant Surgeon to the Seamen's Hospital, who kindly allowed us to make use of his notes and to see the case.)

A horse-bus driver in November, 1906, noticed two "boils" in the neck just below the left side of the jaw; these increased in size for a week, when they were accidentally cut by a barber who shaved him. In two weeks his general health became affected, and a doctor lanced the boils and a lot of "yellowish discharge" escaped. Gradually a large swelling extended around these boils over the whole side of the neck, and the discharge increased in amount. His general health grew worse, and in six weeks from the onset he had severe pains in the calves, which lasted three weeks, and he went to an infirmary. The swelling then spread on to the chest, and two or three small lumps appeared on the chest below the main swelling; these spread and coalesced, perforated the skin in several places, and ultimately fused into one large ulcer, extending from the second left intercostal space to the jaw, 3 in. to 4 in. in diameter, irregular floor and edges, with pus undermining them and discharging dirty-yellow foul pus; in the neighbouring bluish skin were several small, round, ragged ulcers discharging pus. In this state he was admitted to the Seamen's Hospital fourteen weeks after the onset. *B. mallei* were obtained in almost pure culture from the discharge, and corroborated by Professor Hewlett after animal inoculation, the guinea-pig dying in two days with swollen testicles.

Progress.—Active surgical treatment was adopted with a view to removing the entire area of disease, followed by skin grafting; in the course of this the ulcer perforated into the trachea, and into one of the larger veins. He was discharged nine months after admission, cured, and a year later he was perfectly well and had resumed work.

The sputum was several times examined as he had a troublesome cough, but no bacilli were found, and on his reporting himself the cough had disappeared. There was a little pyrexia throughout, but not marked, and there were superadded pyogenic cocci to account for some of this. The serum was examined by us during the healing stage, but no agglutinative action was found.

About three weeks before the onset two of his horses were removed from the stables suffering from some trouble "involving the air passages," though the L.C.C. inspector denied any cases of glanders in the stables.

A study of these cases will reveal the remarkable circumstance that there is but one factor common to all six cases. This is an occupation bringing the individual into more or less direct connexion with horses. In all but Case v there was, in addition, a degree of prostration quite out of all proportion to the clinical signs. In Cases iii and iv it was entirely upon these two observations that even a tentative diagnosis was made, and it was not until bacteriological and inoculation evidence was forthcoming that the nature of the cases was established. So various are the lesions of chronic glanders that the mere fact of an occupation in any way likely to bring the patient into contact with sick horses, whether as coachman, carman, groom, stable hand, or veterinary surgeon, should bring the disease to the surgeon's mind whenever a chronic inflammatory lesion of the oral or nasal mucosae, or an inflammatory mass in the subcutaneous or muscular tissues, presents itself in such a patient.

Acute and subacute cases do not, as a rule, present such great difficulties in diagnosis; nevertheless, many mistakes have been made. The exanthematous eruption, the appearance of which is almost a certain precursor of death, has been mistaken for small-pox (Bosellini, Stewart, Wherry), variella (Gutowski), impetigo contagiosa (Post), herpes zoster necrotica (Bosellini), erythema nodosum (Harte), and anthrax (Bonome). The general febrile state has been mistaken for typhoid (Buseke, Stewart, Goodall, Collie, Ehrlich, Rémy), influenza (Anderson, Harte, Gutowski), pyaemia or septicaemia (Post, Bell, Goodall, Parker, Tedeschi, Ehrlich, and Wherry), acute rheumatism (Goodall, Ehrlich, and Wherry), pneumonia (Post, Collie), typhus (Rémy).

It is to be noted that in the literature there has been a failure to distinguish in description between the lymphatic nodes and the true exanthematous eruptions. Many cases of recovery after the occurrence of "lymphatic abscesses" are recorded, but of survival after the appearance of a generalized cutaneous eruption, few, if any. The cutaneous lesions appear as pink papules, which become vesicular and then pustular. In Case i there was never any

close resemblance to small-pox; but it is obvious, apart from the fact that good observers have made the mistake, that confusion might arise.

All authors are agreed as to the difficulty of distinguishing the lesions of chronic glanders from those of the other granulomata, especially syphilis and tubercle, including lupus. As a distinction between glanders and tubercle, both Besnier and Hallopeau mention the rapid progress of the ulceration, and the tendency to spontaneous healing, which characterize the former. Besnier further states that there is no analogy between the profuse suppuration of glanders and the secretion of lupus. For discrimination between chronic glanders and syphilis we have no criteria, since even the fallible evidence often to be derived from therapeutics is in this case ruled out by the fact that of all the drugs vaunted in the treatment of glanders, mercury is the only one for which success can be claimed with any show of reason.

Whilst these remarks apply to chronic lesions of the mucosae, there is still less to be said of cases such as Nos. III and IV. In very many reports mention is made of some peculiar character of the pus. It may be pink, red, grey, or merely a gelatinous material, quite unlike true pus. To find such contents in an abscess occurring in a patient whose occupation and illness had already aroused a suspicion of glanders would, of course, be so far confirmatory, but in itself the phenomenon cannot be regarded as of high importance.

If we appear to lay too much stress upon these points it is because a common termination of a chronic case is, in an acute outburst, fatal from its inception. The interval of quiescence may be a month or two, or ten years. Here, too, we may point out that, judging from the clinical course of Cases III and IV, it would be extremely easy to overlook their nature altogether.

Some authors have referred to "the typical chancre of glanders"; the term is misleading, and is, indeed, not often met with in the most modern reports. In some cases evidence that a given lesion is the infection point is complete; in many presumptive; but in a very great many it is impossible to do more than hazard a guess as to the means of entry of the virus. In some cases of wounds infected direct from an affected animal the initial site has been considered "characteristic" in appearance, but there is no general consensus of opinion as to the characters.

A case very similar to our No. v, in which for a long time extension took place by continuity only, has been described and figured by Besnier in the *Atlas of Italic Skin Diseases*; Hallopeau and Janselme, Bonomé, and others have described cases of long duration very similar, but in most of them there have been other lesions to afford some clue to the nature of the malady. Upon this fact—the multiplicity of the lesions—Gabrielides and Remlinger lay great stress as diagnostic, but we think this feature is only reliable in the case of the more acute forms.

The Mallein Test.

In three of our cases diagnostic injections of mallein were given. Of these, only five out of six injections were under proper conditions, but in all a typical reaction followed. The constitutional disturbance was not much more than could be accounted for by the pyrexia. Pain at the point of injection and at the site of the lesion was noticed; in three instances there was vomiting, and in one the malaise and restlessness were such that a hypodermic injection of morphine was given. In one instance there was a definite rigor. In one case the temperature rose in five hours to 104.8°; and fell to normal in another thirty-six hours; an injection given the next day led to an immediate rise to 103.4°, with return to normal in eighteen hours. In the other 3 cases the maximum rise—103.8°, 103.8°, and 103.2° respectively—was attained in ten, fifteen, and eighteen hours, and in all three the return to normal was delayed beyond forty-eight hours. In two instances injections of tuberculin were given as controls, but in neither was there any response. It is noteworthy that all 3 cases were "chronic," and that the most typical reaction was obtained from that of longest duration. In several other cases which turned out not to be glanders the mallein test produced no reaction, including 1 case of generalized tuberculous subcutaneous abscesses, which did give a typical "tuberculin reaction."

The dose we have used in all cases is 10 to 15 minims, and this, though the usual dose for a horse, has not produced any untoward results in non-glanderous cases.

Animal Inoculation.

For practical purposes this is perhaps the most reliable diagnostic procedure. In four of our cases it was tried with positive results, and in one the diagnosis was not arrived at until this was done, it being impossible to isolate any characteristic organism from amongst so many contaminating bacteria that occupied the ulcerated surface (Case v). In these contaminating cases it is better to inoculate an emulsion of the suspected tissue subcutaneously into the abdomen of an adult male guinea-pig; if inoculated intraperitoneally the contaminating germs may cause death from peritonitis before the characteristic enlargement of the testes with acute inflammation and engorgement of the tunicae vaginales is produced. The reaction is noticeable in seven to ten days as a rule, but in some few cases it has been delayed for several weeks (seven in one case reported), and in others it has not been obtained at all, and it must be remembered that the bacilli may be present in too scanty numbers to infect.

Liénaux suggests, with good cause, that the *B. mallei* are not always of equal virulence, and hence a certain number are destroyed in the guinea-pig, whilst others of more active character are capable of producing a positive reaction. In one of his experiments with an attenuated culture a positive Strauss reaction was only obtained after ten days, but a typical growth appeared on potato in three days, and so it is advisable to make cultures on potato simultaneously with the animal inoculations.

Bullock and Twort have also found that the virulence of *B. mallei* obtained from human cases, of which they had five, including two acute, is much greater than that from equines, and they got a rapid positive reaction in two or three days. In our Case v, however, a definite reaction was not obtained until the twelfth day, though in the acute cases the response was more rapid.

Valuable results of experimental inoculation with cultures of *B. mallei* have been worked out by Nicolle, who details the various types of lesions following inoculations into guinea-pigs of different ages and sex. He proved the marked vulnerability of the tunica vaginalis of the adult male, the greater resistance of the female, and the still greater resistance of the young male guinea-pig. From this it seems feasible to conclude that several animals should be used, and these adult males only, and that varying doses should be inoculated. Further, he showed that the testicular lesion is not the only one of importance, though in the later stages it is a striking one.

Bacteriological Diagnosis.

The *B. mallei* in the lesions are generally very scanty, and even in the acute abscesses it is often impossible to find them, so that in apparently sterile pus it may be recommended to bear glanders infection in mind. The bacilli are difficult to stain, and are Gram negative, and where there is much cell degeneration the deeply-staining detritus masks the bacilli and increases the difficulty. In four of our cases it will be noticed that in films of the pus from the abscesses only one or two bacilli were found after prolonged search (Fig. 6). They stained well with weak carbol-fuchsin warmed for some time, but we found it much more satisfactory to stain with carbol-thionin blue or carbol-gentian violet after a preliminary treatment with acetic acid, and where the cell degeneration was most marked, as in sections, this latter method was most valuable (see Fig. 7); but in most cases equally good results were obtained with a modified Romanowski's stain. The size of the bacilli and the definite beading are fairly characteristic (see Figs. 6 and 7). With careful staining they were found in greater numbers in the lung tissue of our cases than at first appeared.

In contrast to the difficulties of bacterioscopic diagnosis the cultural characteristics are so definite and so constant as to render the diagnosis simple. Smears of pus.

* Since writing the above, one of us (J. M. B.) has met with an, as yet unclassified, streptothrix which caused a fatal suppurative pneumonitis in a man, and which, when inoculated intraperitoneally into guinea-pigs, causes a rapid and enormous enlargement of the testicles, with immobility, etc., and severe general symptoms. The details of this will be published at length later, but it is worthy of note here.

which is generally uncontaminated in the unopened abscesses or farcy buds, on glycerine-agar produce in twenty-four hours a gelatinous confluent growth, and on potato a brownish growth in forty-eight hours, which later darkens, and after some time may become of a chocolate tint. Compared with the brownish growth of *B. coli* it is darker, more gelatinous, and more luxuriant, yet in one of our cases the organism was at first described as coliform. The question of motility is of importance in this respect.

Note on B. mallei.

The *B. mallei* is by all authors said to be non-motile and often

Fig. 6.—Two bacilli, the larger one showing beading, in the pus taken during life from a superficial abscess. ($\times 1,000$.)

Fig. 7.—Single bacillus seen in focus and two out of focus in section of lung. ($\times 1,400$.)

showing active Brownian movements. The strains obtained by us were to all appearances, however, actively motile, and many individual organisms were seen to move across the field of vision. Repeated observations strengthened our suspicion that the *B. mallei* is truly motile, despite the fact that no flagella could be demonstrated by any method of staining. Mr. E. N. Nelson has for long held that he can see flagella, and with him we are inclined to agree.

There is another point that we wish to note concerning the virulence of *B. mallei*. It appears to be generally taken for granted that the organism soon dies out on culture media and when grown for long as a saprophyte loses its virulence. Our experience with our strains cannot confirm this. A potato subculture from the blood of Case II was kept in the cold incubator for twelve months from August, 1905, and then, even, subcultures from this grew slowly and proved virulent for a guinea-pig. From the organism, reobtained from the animal, subcultures were successively made in November, 1906, January, 1907, and in May, 1907, showing a capacity for remaining alive for months. It must be added, however, that a glycerine-bouillon flask inoculated in May, 1907, failed to give subcultures in August, 1907, the flask containing a prolific mass of organisms arranged in long chains and sometimes branching—a pleomorphism often described. Some of these long kept cultures on potato were inoculated into guinea-pigs in fairly large doses, but beyond raising the temperature and producing some malaise produced no fatal results.

HISTOLOGICAL DIAGNOSIS.

There is only one feature that may perhaps be regarded as characteristic of glandrous lesions, namely, the peculiar nuclear degeneration known as *chromatolysis*. This, indeed, is found in some other necrotic lesions, but in glanders the process is very considerable and constant, beginning very early, so that in small foci the deeply-staining detritus resulting from this degeneration is a striking feature (Figs. 3 and 5).

The question as to whether the lesions are true abscesses or granulomata is still debated. According to McFadyean the former is the case in horses, whilst Unna describes the lesions in man as consisting of epithelioid cells derived from proliferative connective tissue cells. In our most acute case (I), though polymorphonuclear cells were found in films from the pustules in life, the sections *post mortem* showed cells for the most part with round, indefinite nuclei, which may, of course, have contracted after death. In the more recent lesions in the lungs, however, the polymorphonuclear cells predominated; hence we are inclined to consider the lesions as comparable with local abscesses,

with rapid liquefaction and marked chromatolysis, with in the more chronic foci, an additional element in the form of connective tissue cells, due to the proliferative reparative process.*

No giant cells, such as described by others, were found in any of our sections, though the ballooned epidermal cells (Fig. 8) might at first glance be mistaken for giant cells. In Case v, in the light of our present knowledge, we think that the marked chromatolysis in the floor of the ulcer would prevent us overlooking the diagnosis in a similar condition.

BLOOD EXAMINATION.

McFadyean remarks, in discussing the *B. mallei*: "It is a tissue parasite, and in all cases of glanders and farcy in horses the bacilli are almost entirely confined to the lesions and discharges from them; no doubt they are transported by the blood as well as by the lymph, but in horses there is never a septicæmia." Considerable quantities of blood of affected animals have failed to transmit the disease after experimental inoculation, and it is almost impossible to find the

Fig. 8.—Drawing of section of pustule in skin of glanders (Case II). *a*, Thickened epidermis—acanthotic oedema. *b*, Honey layer of epidermis. *c*, Large round bodies containing many round deeply-stained masses probably balloon or swollen epidermal cells. *d*, Sweat gland. *e*, Hair or part of hair follicle from which epidermis has been torn away; cell infiltration consists of round cells (probably polymorphs for the most part). (From a drawing by Dr. H. G. Adamson.)

bacilli in the blood of acute cases in horses.

Sections of lung in Case II bear out this view. In Case II, the only one in which blood cultures were made, the *B. mallei* were only obtained in the blood drawn shortly before death, and it is most probable that this was merely a terminal infection, such as seen in many other infections. Experimentally, also, the organisms after inoculation into the veins rapidly disappear from the blood and become localized; a somewhat analogous condition was seen in Case II, where the

* Duval and White working recently with experimental glanders support this view.

organisms set up an arthritis early in the course of the illness.

Leucocytosis does not seem to be a marked feature; in two acute cases (Picher) there was no leucocytosis, whilst in one of our chronic cases there was a slight increase (19,000), but no increase of the polymorphs; and in an acute case of Wherry's there were 21,000, but he does not mention a differential count.

Agglutination Test.—In horses McFadyen has obtained positive agglutination phenomena in very weak dilutions—1 in 1,600 as compared with 1 in 300 in healthy animals. Dr. Eyre tells us that in 3 cases recently admitted to Guy's Hospital the serums agglutinated *B. mallei* in dilutions of 1 in 100. In our Case it no definite results could be obtained, and various observers have obtained different results; but at present the value of this diagnostic procedure must be regarded as indefinite.

Mode of Infection.

In none of our cases was there definite evidence of the point of inoculation or path of infection, and the general evidence, clinical and experimental, on both these questions is so conflicting that the time is hardly ripe for the expression of decided opinions. The hypothetical paths are by direct inoculation through a wound or by the hair follicles, by inhalation or by ingestion.

Direct wound infection is conclusively proved by laboratory accidents; glands has been assigned as the most frequent cause of accidental death amongst laboratory workers.

As to the hair follicles, Babes performed numerous experiments on guinea-pigs, rubbing in an emulsion of *B. mallei*, and succeeded in producing infection. Nocard, however, repeated the experiments with indefinite results.

Infection by ingestion has been definitely proved, in horses, by MacFadyen, but the comparative frequency of respiratory lesions and the infrequency of abdominal, in man, suggests that the problem will be as difficult of solution as that which has to be faced in the case of tuberculosis. Gutowski pointed out that ward infection does not occur, and in this connexion we may record that one of our acute cases on several occasions was allowed to breathe through an apparatus containing glycerinated broth, which however remained sterile. It is obvious that no stress can be laid on an experiment under such conditions. The fact remains, however, that contact, not only directly with infected sputum and discharges, but even with soiled fomites, may be dangerous.

Weichselbaum and Phillipowicz have recovered *B. mallei* from the urine, and Cao from the milk of sick mares. Cao also observes that the *B. mallei* remains virulent after passing through the alimentary canal of flies and other insects.

Although it is generally recognized that knackers and others dealing with glandrous carcasses are rarely infected, yet the case is different with man, because the disease is necessarily allowed to proceed to the bitter end; and it is only in the latest stages that the organism becomes generalized in the blood, which is then highly infectious.

Extension from a primary local lesion, if it occurs, does so in the first instance by the lymphatic vessels; and this, unlike the blood infection that may ensue, is not necessarily fatal.

Latency of the bacillus in the tissues is well recognized, for the records show many cases in which entire quiescence was observed for several years, yet admitting of a fatal outburst. Babes states that he found encapsuled glandrous nodules in the viscera—especially the lungs—of knackers and others dying of some other disease, and discusses the question of occult glands.

The incubation period varies within wide limits. For instance, in the recent Czernowitz laboratory accident the disease broke out amongst several of the staff in a few days after the scattering of the bacilli by the breaking of a centrifuge tube; in Stewart's case, after the autopsy on a guinea-pig, the first symptom appeared in six days; in Picher's case, six weeks after a bite by a glandrous horse.

In conclusion, we must express our thanks to Dr. Hebb for much valued advice; to Dr. Colcott Fox for kindly having had made for us the photomicrographs (Figs. 6

and 7); and to the staff of the hospital and to Mr. C. C. Choyce, for permission to make use of their cases.

ANAESTHESIA IN THE HUMAN SUBJECT* WITH KNOWN PERCENTAGES OF CHLOROFORM VAPOUR.*

By N. H. ALCOCK, M.D.,

LECTURER ON PHYSIOLOGY TO ST. MARY'S HOSPITAL MEDICAL SCHOOL.

INTRODUCTION.

THE theory and practice of anaesthesia are too often spoken of as distinct and even antagonistic entities. This view is founded on a misconception. Theory is based on practice, and on that alone; and if in practice by careful and accurate measurement any facts appear that are not accounted for by the theory, this must be due to some error in the latter.

There is, however, a suppressed premiss in the statement of the case that is often the unconscious basis of such ideas. It does not necessarily follow that the facts observed on healthy animals can be applied without correction to the pathological conditions often met with in the human subject. It is, therefore, by no means waste of time to examine as carefully and accurately as may be, details of anaesthesia in man that have already been carefully studied in the lower animals, and this is what has been attempted in the observations that are recorded in the present paper.

It is, perhaps, a truism to say that our knowledge of any subject is in direct proportion to the accuracy with which exact measurement can be applied to it. Yet this

* Read before the Section of Anaesthetics, Royal Society of Medicine, on December 9th, 1908.

self-evident statement is sometimes lost sight of in cases like the present, where measurement is often difficult and in some cases still impossible. But the ideal should always be kept in mind, and one should not feel satisfied with our knowledge of anaesthesia until we are able to predict exactly what effect will follow from the inhalation and absorption of a known quantity of the drug employed.

We are still very far from this ideal, but in the present paper one of the initial steps is now taken—namely, that of measuring the percentage in the inspired air.

No attempt has been made to estimate the amount of chloroform absorbed or to trace the fate of such absorbed chloroform in the body, though these factors are of supreme importance in the action of the drug. Yet in justification of the limited scope of our subject it may be urged that the percentage in the inspired air is the only factor that is under the direct control of the anaesthetist, and it is the immediate cause of all effects produced.

APPARATUS.

In order to ascertain the strength of the chloroform vapour at any moment it is necessary to deliver this from some form of machine. Two methods are available for the construction of such apparatus. The first—that employed by Snow, Vernon Harcourt, and Levy—is that where the patient draws the air through the apparatus by means of his respiratory muscles, the so-called "vacuum" system. While this method lends itself to the construction of a small and compact instrument it has the disadvantage that it places some obstruction in the way of free respiration. Whether this does much harm or not, it at least introduces an additional factor, and accordingly the second method—which has been used by Dubois, Waller, and Roth-Drager—has been preferred. In this case the mixture is supplied to the patient by mechanical power, the so-called "plenum" system.

The apparatus finally adopted after a long series of trials was of a very simple type. It has been already described in this JOURNAL.¹ Briefly, it consists of a circular copper vessel 5 in. in diameter and $\frac{1}{2}$ in. deep, which contains 150 c.cm. of chloroform; $1\frac{1}{2}$ in. from the bottom is fixed a shelf closed except for two oblong holes. Immediately above and touching this shelf is a circular plate, movable by means of a hollow rod in the centre, and pierced by two triangular apertures. These can be adjusted by the centre rod so as to expose more or less of the fixed oblong holes in the shelf, and so produce greater or smaller openings into the space below. Air (supplied from a small foot bellows or from an electric fan) enters the chamber by one tube opposite one aperture, and leaves by another tube, opposite the other, taking up more or less chloroform vapour according to the size of the apertures. A thermometer in the hollow rod indicates the temperature of the chloroform below, and a water jacket surrounding the chamber serves to keep the temperature between certain limits.

The first thing to be determined in an apparatus of this kind is the degree of accuracy with which it works under actual conditions of surgical anaesthesia, and this may be a very different thing from the accuracy obtained in a physiological laboratory. In the latter case all that is required to reduce the instrumental errors to a minimum is the careful application of the ordinary principles of physics, but in the anaesthesia of the human subject the first care is the condition of the patient, the second the necessities of the surgical procedure; and it is only when these requirements are satisfied that the observer can take the steps necessary to test the accuracy of the apparatus.

The possible errors can be classified under three headings:

1. Errors of the method used in testing.
2. Errors of the chloroform apparatus itself.
3. Unknown errors due to the necessities of the surgical procedure.

1. Errors of Method.

The percentage of chloroform was determined by means of the densimetric method introduced by Waller and Geets.² Levy³ has shown that this method gives practically identical results with that of the combustion method of Vernon Harcourt.⁴ The maximum error under ordinary conditions does not exceed 0.1 per cent.—that is,

2 per cent. vapour may be read by the densimeter as 2.05 or 1.95 at the worst. As the smallest variation that can be perceived on the patient is 0.25 per cent., this limit of accuracy is amply sufficient.

2. Errors of the Apparatus itself.

The following points were specially tested:

(a) *Errors of Repetition.*—Repeated determinations were made of percentages nominally the same. The results were:

1st Reading.	2nd Reading.	3rd Reading.	4th Reading.
Per cent.	Per cent.	Per cent.	Per cent.
(a) 1.15	1.15	1.15	—
(b) 1.3	1.35	1.35	—
(c) 1.65	1.6	—	—
(d) 2.5	2.4	2.4	2.4

These readings combine both possible errors, yet the greatest variation of any one reading was 0.2 per cent., and the usual variation about 0.1 per cent. or less.

(b) *Temperature Errors of the Densimeter.*—Waller and Geets give a formula for this correction, but as the conditions were rather different in the present series of experiments, direct determinations were made. The following values were found:

Temperature Fahrenheit.	Grain.	Mean Percentage Correction.
46.0	-0.0025	+0.23
44.5	+0.0020	—
66.6	-0.0010	+0.05
65.6	-0.0005	—
81.0	-0.0016	-0.2
81.2	-0.0015	—

Room temperature, 70° F.

These corrections have, therefore, been applied at the appropriate temperatures.

3. Variations in the Air Supply.

In the special form of apparatus used, air is pumped through the chloroform chamber in a steady stream by either a foot bellows or else by an electric fan. Both sources are apt to vary, so that the point was specially examined.

Air in Litres per Minute	Percentage of Chloroform.	Mean.
20.0	2.15 2.05	2.10
12.5	2.15 2.25 2.20 2.15	2.19
8.5	1.90 2.00	1.95

The percentage is therefore practically constant between 20 and 8.5 litres per minute.*

Below 8.5 litres per minute the percentage falls, so that if the assistant forgets to pump or the electric fan works badly no harm is done. The usual air supply is between 16 and 20 litres per minute; as it is given in a constant stream it is required to be double the normal ventilation of the lungs, which is about 10 litres per minute for the average adult.

4. The Presence of Impurities in the Chloroform.

After the apparatus has been in use for two or three hours the chloroform is often turbid from the condensation of the water vapour in the air. This in the quantities present causes a very slight error.

Normal.	With Water.
(a) 2.55	2.50
(b) 1.1	1.15
(c) 2.1	2.05

* A. G. Levy points out (*Lancet*, May 27th, 1905) that the percentage of chloroform will be independent of the air current when in any machine the stream of air is divided, so that part passes over the liquid chloroform and part direct to the patient, the perfection of adjustment depending on the relative velocity in the two paths and the amount in which viscosity comes into play in the chloroform airway. In his apparatus, which is of the "vacuum" type, the percentage was constant between the limits of 33 litres and 9 litres air stream per minute.

5. Unknown Errors in the Operating Theatre.

Finally, it might be said that under the exacting conditions in actual practice the apparatus might develop unknown errors. A typical case was therefore selected, and in the laboratory was rehearsed again in dummy, the conditions being exactly the same, except that a densimeter bulb was put in place of the patient.

Theatre Reading. Per cent.	Laboratory Estimation. Per cent.
1.0	1.1
2.5	2.4
2.5	2.55
2.5	2.4
2.0	2.1
1.75	2.7

This case is graphically represented in Fig. 1.

Fig. 1.—Case XXXIII. Boy, aged 9. (Undescended testicle, Mr. Collier.) Dr. Beaumont. Repetition of curve. Crosses mark the actual estimations in the laboratory.

TYPICAL CASES.

This preliminary work being disposed of, it was then possible to study the effect of known percentages on the human subject with some confidence that the nominal amounts were really administered.

The records of the first 50 cases form the basis of this communication. While this number may seem very small to the professional anaesthetist, who counts his administrations by thousands, and while it certainly is too small to allow any conclusions to be drawn as to the frequency of the more unusual occurrences, yet it is quite sufficient to provide a good deal of information on the more common features of anaesthesia in the ordinary type of case.

Full notes were taken of each administration in the customary manner. But on reflection it became evident that as two factors were accurately known—(a) the percentage inhaled and (b) the time—it was possible to plot these figures on squared paper so as to show the progress of anaesthesia in a graphic manner. Time in minutes is measured along the abscissa and the percentages of chloroform along the ordinates, and Fig. 3 may be taken as a typical curve from an average case.

Such a curve deserves a little study. The first thing that is evident is the little break in the administration that occurs about the eighth minute (more or less according to circumstances). This represents the passage of the patient from the anaesthetizing room to the operating theatre, and conveniently divides the record into two parts—(1) the period of induction, (2) the period of surgical procedure. Theoretically this break is a disadvantage, and it has always been made as short as possible. It serves, however, to mark the point at which the patient is ready for operation, and so it has been taken as the end point of the induction period.

During this time the curve indicating the percentage rises gradually, and in the majority of the cases a regular routine was followed. An arbitrary rule was made that the percentage should have the same figure as the time; in other words, during the first quarter-minute the percentage was 0.25, at the half-minute it was 0.5, in one minute it was 1, in two minutes 2. After this point the rise was made more gradually, and depended on the condition of the patient; in an average case 2.5 per cent. was reached in three minutes, and if necessary 3 per cent. in four minutes.

Several considerations determined this routine. It is necessary to remember, on the one hand, that a high percentage—over 2—is dangerous in the early periods of anaesthesia, as Waller has shown. The absorption of chloroform is most rapid in the second minute (Brodie and Widdowes), so here again a low percentage is indicated.

Further, if 2 per cent. is given at once, the patient is apt to cough and struggle, so that it is necessary to begin slowly. On the other hand, time is valuable; for most cases eight to nine minutes should suffice for induction, and no surgeon likes to wait for twenty minutes while the patient is being prepared for an operation lasting but ten. There are other reasons, which are under investigation at the present time, why it is undesirable to prolong the period of induction further than safety dictates. So that the apparently arbitrary rule that was adopted is not without justification on theoretical grounds, and experience proved that it worked very well in practice. The patients go under very evenly and gradually, there is no discomfort, and there is a marked lessening of the usual struggling or excitement; very often there is no struggling at all.

It is not possible yet to state definitely that this arbitrary rate is invariably safe, as the present series is too short to give definite data, but no sign of danger was to be seen in the induction of any of the cases.

Sometimes a slower rate was used with good results, especially in very thin nervous subjects and in children. In the earlier cases this slower rate was tried in ordinary cases, but here no advantages were seen, and many disadvantages, so that the arbitrary rate was finally adopted.

The patient was usually ready for operation in about eight to nine minutes, the minimum time being six minutes, the maximum twelve and a half (Fig. 2), so that anaesthesia with these known percentages need not take an unreasonable time.

It is possible to make some interesting comparisons with the "open" method. It is usually supposed that this is specially expeditious, but in the cases I have actually timed the induction period lasted from eight to ten minutes, sometimes longer. To judge from the condition of the patient, one would guess (it is little more) that ordinarily during this time the open cone gives more than 2 per cent. in the first two minutes, and less than 3 per cent. in the last four minutes. Exact determinations

Fig. 2.—Case XVI. Female, aged 30 (Appendicitis. Mr. Clayton-Greene.) Dr. Beaumont. Stout patient taking much chloroform.

of what is really given would be of great interest. One would expect to find that while the skilled professional anaesthetist would give percentages not differing greatly from what has been suggested as the optimum, the less skilled learner is much less happy in his choice.

The second half of the curve, that which has been termed above the "period of surgical procedure," is usually (as is well shown in Fig. 3) marked by a gradually decreasing series of steps; 2 per cent. is generally required up to about the twentieth to the twenty-fifth minute

Fig. 3.—Case XXXVII. Female, aged 37. (Tenoplasty, Mr. Pepper.) Dr. Beaumont. An average case. Figures on the ordinate represent percentages of chloroform. The abscissa shows the time; each division is equal to two minutes.

(Figs. 1, 3), then 1.5 per cent. to the forty-fifth minute, but the percentages in this part of the curve vary greatly. In Case XLIX, for example, 1.5 per cent. was used from the twenty-first minute till the sixty-sixth; in Case XXX, 0.75 per cent. was given from the sixtieth minute to the one hundred and thirty-sixth, but in the majority of the cases the values are of the order given. As in any other mode of administration the percentages must be increased a little if the patient vomits, and it is well to increase the amount slightly before the skin is sutured if the

patient is on a low percentage, or if, as in gastro-enterostomy, special relaxation is required; but usually this precaution has not been necessary.

INDIVIDUAL VARIATIONS AND UNUSUAL CASES.

The description given above applies to the great majority of the fifty cases. While it is true that no two cases are exactly alike, yet when the patient is an average specimen of adult age and the operation is not one of especial difficulty, it is found the anaesthetic curves show great similarity, and it is not necessary to describe each one in detail. One can therefore turn to the next chapter—namely, the consideration of the individual variations and the unusual cases. These can be classified under four main headings: 1. Age. 2. Build. 3. Alcoholism. 4. Operation required.

With regard to these subdivisions, it will be necessary to have a much larger series of cases to enable very precise conclusions to be drawn, still certain preliminary observations can be ventured upon with a considerable degree of accuracy.

1. The Effect of Age.

No very old persons were included in the series, but there was a very definite little group of five children, with an average age of 10 years, which can be compared with the typical adult. As a rule less chloroform was required

Fig. 4.—Case XI. Boy, aged 11. (Wiring fracture, Mr. Clayton-Greene). Dr. Beaumont. Takes less chloroform than the type.

(Fig. 4); one case, however, took an amount quite equal to the normal.

2. Build.

This appeared to have a marked influence. Fat persons took much more chloroform than thin, and Figs. 2 and 5

Fig. 5.—Case XIII. Male, aged 34. (Appendicitis, Mr. Clayton-Greene). Dr. Blumfeld. Slightly built and thin. Took very little chloroform.

are excellent examples. These cases had the same operation, on the same day, performed by the same surgeon, and the amount of chloroform required is much more in the case of the stout woman than the thin man. Of the 50 cases, 5 were distinctly spare and 4 very fat, and the same rule held throughout.

It must be remembered, however, that the number of cases is too few to enable a general inference to be made, and Dr. Levy has drawn my attention to a thin patient that took a quite abnormal amount of chloroform, so that other factors must have some influence on the result. Case VII is, perhaps, an example of this—there was a slight tendency to goitre, and the percentage used was much less than the average.

The subject is one of considerable interest from the theoretical point of view, and experiments on the subject are in progress. The objection might be raised that all fat hospital patients are so because they are alcoholic, and should therefore be included in the next section, but on this point no certain information was forthcoming.

3. Alcoholism.

These persons took more than the average, even when not of especially stout build (Fig. 6).

One patient, a big, muscular man of 34, alcoholic, and requiring immediate laparotomy as the result of an "accident" (he had been stabbed in the abdomen just below the liver), took so much chloroform that the machine,

even at 3.5 per cent. did not give enough, and the case was finished with the cone (Fig. 7). Here the open method must have yielded more than 4 per cent. at the least.

Fig. 6.—Case XXIX. (Ventral hernia, Mr. Lane). Dr. Beaumont. Alcoholic patient of average size. Takes more chloroform than the type.

4. Effect of the Operation.

The most obvious variation is shown where a very prolonged operation is necessary. Case XXX, lasting two and a quarter hours, was kept perfectly anaesthetized at 0.75 per cent. for the last ninety minutes.

A very important point was observed by Dr. Beaumont, which had been previously suspected, but of which the proof had been wanting. A patient is being kept quite evenly under, and a steady percentage—say 1 per cent.—has been given for some time. The operation procedure is of an ordinary type, and the corneal reflex is just absent. Now if the surgeon, by pulling on the parietal peritoneum, excites violent afferent impulses, the corneal reflex comes back, and the patient becomes less deeply anaesthetized even if the percentage remains the same.

Dr. Mathison and I verified this on animals, and we observed in addition that the blood pressure falls, and the respiration is quickened and increased in depth.

The inference is important. Ordinary anaesthesia is due partly to the direct action of the drug and partly to a condition closely analogous to sleep. Violent afferent impulses remove this latter factor, exactly as in poisoning by morphine, where the patient can be roused by shaking, to sink back into narcosis when the stimulus ceases.

The reflex quickening and deepening of respiration is also worth noticing from a practical standpoint. The patient in this condition is taking in more chloroform than before, and every anaesthetist is aware of the possibility of an overdose being given under these circumstances.

The account of this series would not be complete without the notes of those cases where, by mistake or other cause, the result was not what was expected. Four cases were abnormal in this respect. Case XXXIV (Fig. 7)

Fig. 7.—Case XXXIV. Man, aged 34. (Exploratory laparotomy, Mr. Pepper). Dr. Beaumont. Case requiring more than 3½ per cent.

has been already referred to, and it must be admitted that here the machine was at fault; such cases can only be dealt with by special means.

In Case XII induction was completed by the open method, but here the standard rate of increase was not adopted, and the case should hardly be counted a failure.

In Case XXXVIII death occurred two hours after the patient had been removed from the theatre. The case

Fig. 8.—Case XXXVIII. (Hydrocephalus.) Male, aged 22. Artificial respiration at arrow (38th minute). Death two hours after removal from theatre (2 hr. 43 min.).

was one of suspected cerebellar tumour; on opening the cranium no tumour was found, and the patient's condition

became so unsatisfactory that the anaesthetic was discontinued, and the incision rapidly closed. Eight minutes after this artificial respiration became necessary, and after two hours the heart stopped. *Post mortem* there was great dilatation of the ventricles of the brain, and the existence of basal meningitis prevented the opening of the cranial cavity relieving the pressure.

Case x presented some interesting features. The anaesthetist was using the apparatus for the first time, and

Fig. 9.—Case X. Man aged 36. (Ventral hernia, Mr. Clayton-Greene.) Description in text.

found some difficulty in translating his knowledge of anaesthesia into the percentages given by the machine. Induction was too slow (it was before the standard rate had been adopted), and when the patient was moved to the theatre a mask was placed over his face in transit. This evidently gave a higher percentage than was expected, and the result was that after a latent period of one minute the breathing became embarrassed, and artificial respiration had to be performed, ether being used to keep up anaesthesia. The patient came round in a very satisfactory manner, and then was given 1 per cent., and later 0.5 per cent. This latter amount, as can be seen from the other curves, was much too little for the stage of anaesthesia, and the patient began to recover consciousness; 3 per cent. was then hastily given, then 2 per cent., and finally the machine was abandoned and the mask used to finish the operation. The difficulties met with were evidently the result of the use of an unfamiliar method, but one valuable piece of information was disclosed, namely, that the effect of an overdose is not immediately seen, requiring about a minute to become evident.

CONCLUSIONS.

There are many things observed from time to time in this series that fall under the class of unmeasurable phenomena. It is hoped that future work may remove at least some of these into the category of accurate measurements, when they can be considered with more certainty than is now possible. Particularly would one wish that numerical values could be assigned to the individual variations and to the post-chloroform effects that are now so meagrely dealt with. But, from the facts recorded above, the following points may be noted as reasonably certain.

1. Anaesthesia with known percentages of vapour in man at least as easy and certain as by the ordinary method, even when the latter is carried out with the greatest skill.

2. If it is desired to induce anaesthesia in from eight to ten minutes, the ordinary adult must be given percentages rising to 2 per cent. in two minutes, then to 2½ per cent. in three minutes. This amount usually will suffice. There is no objection to raising the percentage to 3 per cent. in five minutes (not sooner) if it is required, *provided due care is exercised*.

3. When induction is completed, 2 per cent. is usually ample, gradual diminution to 1.5 per cent. and 1 following in about twenty to twenty-five minutes, and the anaesthesia can be maintained in this way much more easily and regularly than by the open method.

4. Children generally require less than the above amounts, 2 per cent. for the induction and 1.5 per cent. for the later stages. Some thin adults will also require less than the average, some fat, muscular, or alcoholic adults more, but the data are not sufficient to furnish more precise rules.

5. From the above it is evident that the general features of anaesthesia are the same in man as in the other mammalia. Minor points of difference are seen in the greater individual variations and in the percentages required, 2½ per cent. in man being approximately equal to

2 per cent. in the cat. When due allowance is made for these differences, it is legitimate to apply the conclusions deduced from experiments on animals to the human subject. When it is remembered how conclusively Waller has shown the much greater safety of a known percentage in animals, the importance of the inference can be seen.

Finally, it is again my pleasant duty to convey my thanks to my colleagues at St. Mary's Hospital, who have in every way given me the kindest assistance. Particularly are my acknowledgements due to Dr. Blumfeld, Dr. Collum, and Dr. Beaumont, to whom the credit of the practical success of the method largely belongs.

ATROPHIC RHINITIS COMPLICATED BY MASTOID ABSCESS AND EXTRA-DURAL ABSCESS.

By FRED. STOKER, M.B., F.R.C.S. EDIN.

So far as I am aware atrophic rhinitis is not a common cause of mastoid suppuration, particularly in the absence of signs of middle-ear suppuration.

Mrs. M. A. S., aged 30 years, came to me on November 5th, 1908, complaining of pain over the mastoid and frontal areas. She had had atrophic rhinitis for twelve years, and had been treated in various ways without any benefit. The right ear had been partially deaf for four years, the deafness coming on gradually. She had had no pain in the ear until lately, and never had otorrhoea according to her own, her mother's, and her husband's testimony. No history or signs of syphilis or tubercle.

On November 5th she complained of intense pain over the right mastoid and frontal areas, tenderness over the same and on pressure on the right tragus. The post-auricular gland was enlarged, but as her head was infested with pediculi great weight was not attached to this, particularly as she said it had been in much the same condition for months. Temperature 103.5°, pulse 120. No rigors or signs of intracranial mischief. Both nostrils were wide and partly covered with stinking crusts. The left inferior turbinal had been removed. The septum was deflected to the right. By posterior rhinoscopy the Eustachian orifices were seen to be dilated and the walls and roof of the naso-pharynx dry, glazed, and covered with adherent crusts. On examining the right ear no perforation could be seen in the membrane, which was opaque, thick, white, and immobile with Siegle's speculum. Rinne's test was negative; the watch could not be heard at all; Weber's test was referred to the right side. There was no redness, swelling, or oedema over the mastoid process nor was the auricle displaced.

Leeches were applied in front of and behind the auricle, followed by large fomentations. Drops of a solution of cocaine and ac. carbolic. (āā gr. v) in glycerine (5j) were instilled into the ear and a purgative given.

The patient felt much relieved, had a fairly good night, and next morning (November 6th) the temperature had fallen to normal, the pulse to 96. She still, however, had a great deal of pain and tenderness. The same night she became much worse, and a swelling became apparent above and behind the auricle, displacing it downwards and outwards. Operation was advised, and early next morning (November 7th) the mastoid antrum was opened, giving exit to over a drachm of thick yellow pus. Considerable bone destruction had gone on posteriorly, therefore the lateral sinus was exposed, and a rough curet was used to remove granulations from its external aspect, it was not thrombosed. The mastoid cells were thoroughly opened up, the mastoid antrum, almost as large as a Barcelona nut, was curetted, the patency of the aditus assured, and the cavity packed with gauze. The temperature, taken immediately before operating, was 100° F.; after the operation it was normal.

From this time until November 13th, she did well generally, except that the pulse was rapid (see chart), but still complained of intermittent frontal pain and tenderness. On this date facial paralysis of the right side was noticed, but it was by no means marked. I considered it might be due to inflammatory thickening near the stylo-mastoid foramen in the death of other symptoms, and could not decide that the head pain was due to intracranial mischief, as she had no other signs of such trouble, such as rigors, vomiting, optic neuritis, spasmus of limbs, vertigo, or the pulse or temperature of brain or meningeal disease, although the two last symptoms are known to be uncertain quantities. Her mental condition was clear and alert, but she was very restless.

On November 14th the facial paralysis was worse, and at night the pain was intense, and had extended over the right side of the head. There was tenderness on pressure over the squamous portion of temporal bone. The temperature was normal, and the pulse 110. There was no vertigo or other signs of involvement of the intracranial portion of the auditory

nerve, therefore it was concluded that the paralysis was due to pressure on the facial nerve in the middle ear, where possibly the bony wall of the aqueduct of Fallopius was deficient. Extradural abscess over the tegmen tympani was considered as a probable solution of the cause of pain, and on November 15th the previous operation was extended and the complete mastoid operation performed. The middle ear was filled with granulations, and no trace of the ossicles could be seen. The cavity in the bone was enlarged by cutting upwards and the middle fossa opened. The dura was covered with granulations but did not bulge. A probe passed under the dura in a forward and inward direction entered an abscess cavity $\frac{1}{2}$ in. from the opening, and about 1½ drachms of thick, yellow, foul pus escaped. Good drainage was secured and the wound gently packed with gauze and drained posteriorly. The mastoid wound was also packed and drained through the auricle, from which a flap was cut. The temperature and pulse before operation were 99° and 100 respectively; after it they fell to 98.2 and 72. The patient became exceedingly restless in a few hours, having to be held down in bed; $\frac{1}{4}$ grain of morphine was given hypodermically and secured sound sleep for eight and a half hours.

November 16th. Much quieter, but still restless; slow cerebration; no pain in head; pupils equal and active; some stiff-

It would undoubtedly have been better in this case to have explored the middle fossa at the time of the first operation, as well as the lateral sinus. This procedure would not have unduly prolonged the operation, and much valuable time would have been saved.

It has since appeared to me that a more effective route for draining the floor of the middle fossa might be obtained where the complete mastoid operation is done, if the infero-lateral opening usually made was continued inwards and forwards by removing the roofs of the external meatus, middle ear, attic, and antrum. The external semicircular canal would not be in danger if a bent probe were kept over it, and the others could be safeguarded by cutting, as before noted, inwards and forwards. (See figure.)

In the above diagram 1 corresponds to area over glenoid cavity; 2, to area over external auditory meatus; 3, to area over mastoid antrum; 4, to area over middle ear; 5, to area over Eustachian tube; 6, to area over internal ear; 7, to position of lateral sinus. The area outlined in coarse is that to be removed.

○, Operation. □, Death.

ness of back of neck; both knee-jerks very active. No other signs. Basal septic meningitis diagnosed and but prognosis given; pulse 84, temperature 97.9; facial paralysis much improved.

November 17th. Pulse 104, temperature 100°. Drowsy, restless, and irritable, reminding one very much of the picture of the first stage of cerebral irritation. Has vomited a little (one mouthful) once without retching. No pupil disturbance or other cranial symptom, except those present yesterday. Facial paralysis scarcely perceptible; taking nourishment fairly well.

November 18th. Cannot be roused. Conjunctiva insensitive. No squint, pupils equal. Pulse 132, respirations 46, no stertor. Later, pulse 144, respirations 48 and of Cheyne-Stokes type at intervals, temperature 100 F. Perfectly quiet, with an occasional gentle movement of the hands and arms, not at all convulsive in character.

November 19th. Died quietly at 8.30 a.m.; no autopsy obtained.

The infective process in this case had evidently passed from the naso-pharynx to the middle ear and destroyed the ossicles, and had also invaded the antrum and gradually rarefied the mastoid bone. No symptoms occurred, however, until the aditus became blocked with granulations or swollen mucous membrane, as until then a free road was available into the naso-pharynx for the products of inflammation. When the block occurred the symptoms appeared—the result of tension.

When the signs and symptoms set down as characteristic of intracranial disease, such as rigors, vomiting, optic neuritis, pupil changes, convulsions, hydrocephalic cry, etc., are absent, one is liable to be lulled into a false sense of security. Until the last two days of life of the patient whose case has been described, restlessness was the most noteworthy symptom. It was characterized chiefly by the continual efforts of the patient to get up on her hands and knees; she would stay in that position for a moment and lie down again. This sequence would sometimes occur five times in as many minutes.

A CASE OF OEDEMA WITH RESOLUTION BY URINARY CRISIS.

BY

H. D. ROLLESTON, and

F. L. GOLLA.

M.D., F.R.C.P.

M.B., M.R.C.P.

SENIOR PHYSICIAN TO ST. GEORGE'S HOSPITAL.

ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL.

This case of what may be called a urinary crisis in a man with chronic parenchymatous nephritis is worth recording, if only on account of the phenomenal loss of 4 st. 3 lb. in four days coincident with the disappearance of oedema.

The patient, a man 27 years of age, got wet through twelve days before admission; nine days before admission he had abdominal pain, diarrhoea, sickness, and malaise; a few days later oedema was noted, and one day before admission phlebitis of the left thigh appeared. Eight years ago he had had an attack of kidney disease with oedema. On admission on July 11th, 1907, he had oedema of the legs and lower part of the abdomen, and thrombo-phlebitis of the left femoral vein. The urine—specific gravity 1028—contained a considerable amount of albumin, and showed diminution of chlorides, but there were no casts or blood. There was no hypertrophy of the heart, and the blood pressure was 100 mm. of mercury.

The phlebitis soon subsided, but the general oedema increased. On July 26th he weighed 11 st. 12½ lb.; on September 9th, 12 st. 1 lb.; on September 14th, 12 st. 10 lb.; on October 10th, 13 st. 11½ lb.; on October 16th, 14 st.; and on October 23rd, 13 st. 7½ lb. The average amount of urine passed was about 30 oz., and the intake of fluid was restricted for most of the time to 60 oz. From the time of his admission various means of reducing the oedema were employed, but without effect. He had successively and in different combinations theocin, caffeine, hot air baths, pil. digitalis co., puncture of the legs. For a period of four weeks, when in the summer Dr. Spriggs looked after the patient, the amount of fluid taken was not restricted. These measures did not have any beneficial effect. On October 5th he developed an attack of cellulitis of the left groin and lower part of the abdomen on the left side, which soon passed off. On October 16th his weight, as already stated, was 14 st.; it then slowly decreased, and a week later (on October 23rd), when it was 13 st. 7½ lb., the amount of urine suddenly increased from 48 oz. in twenty-four hours to 98 oz., and on the succeeding days was 112, 166, 180, 160, 204, 112, 138 oz. The hot-air baths were then stopped (on October 30th), and the amount then fell to 84 and 60 oz. on October 31st and November 1st; by this time the oedema had completely disappeared. On October 31st he weighed 9 st. 4 lb., having lost 4 st. 3 lb. since October 27th, and after losing 2 lb. more, his weight increased to 9 st. 6 lb., when he left the hospital free from oedema on November 12th. After the sudden disappearance of oedema he

OCTOBER.

Chart showing weight of patient, amount of fluid taken, and of urine excreted in the twenty-four hours, and temperature (continuous line) and blood pressure (interrupted line), of a man with chronic nephritis who lost 4 st. 3 lb. in weight and extensive oedema in four days.

had some slight headache and felt weak, but did not suffer from thirst.

The loss of over 4 st. in four days was so remarkable that the weighing machine was carefully tested in order to exclude any fallacy, but it was perfectly accurate. The alteration in the man's appearance produced by the disappearance of the oedema was very remarkable. In 1905 Dr. Atlee and one of us (H. D. R.) recorded a case of a man with chronic nephritis who lost 4½ st. in weight in sixteen days, or at the rate of 4 lb. a day, as the result of disappearance of oedema and diuresis, which was then ascribed to the use of caffeine citrate.¹

To arrive at some understanding of the nature of this process of resolution of oedema by urinary crisis, it is necessary to recapitulate briefly the following points in the history of the above case. The patient had been given hot-air baths daily from October 15th. On October 16th his weight was 14 st. The baths caused only very moderate sweating, and during the next seven days the weight diminished only by 2½ lb. As will be seen by reference to the table, the urine fluctuated during this period between 38 to 50 oz., and similar fluctuations had been the rule during the preceding three weeks. On October 22nd the increased excretion began and continued for eight days, returning to about the normal excretion on the tenth day, whenceforward it remained fairly constant, about a mean of 56 oz. From October 23rd till October 30th the patient lost 56 lb. in weight, and, inasmuch as he still continued to assimilate an ample milk diet, the whole of the loss of weight may safely be attributed to the subsidence of the oedema. During this period the excess of urine excreted over the ingested fluid, calculated at a mean specific gravity of 1008, only accounts for a loss of weight of 39 lb., the remaining 17 lb. must therefore be accounted for.

During the period under consideration the bowels were constipated, and only open on alternate days, the faeces being very hard and firm. Since the faecal evacuations would not account for any appreciable loss of fluid, it is obvious that the loss of weight must be attributed to the increased secretion of sweat,² which during this period was very profuse; the patient lay in a constant bath of perspiration, and his sheets had to be changed frequently. It is true that during the whole of this period the hot-air baths were continued daily, but the loss of weight due to the influence of the baths has been shown to have only averaged 3 lb. in seven days before the onset of the crisis, so that during the crisis the loss of weight by sweating must have averaged 2½ lb. a day.

The blood pressure was recorded at intervals during the whole period of his illness, and was practically stationary at 140 mm. Hg till the day after the onset of the crisis, when it began to fall, reaching 130 mm. Hg on the fourth day, at which point it remained stationary till the patient's discharge. The cause of the subsidence of the oedema cannot therefore be

sought in an increased activity of the heart, nor can the fall of blood pressure, coming as it did after the first day of the crisis, be interpreted as other than that due to relief of the peripheral constriction caused by the subsidence of the oedema. Unfortunately during the crisis it was not possible to carry on observations on the urine other than a perfunctory record of the specific gravity.

The case is of interest on account of the light that it throws on the problem of oedema. The well-known *verdünnungsversuch* of Kovesi and Röth-Schulz² has directed attention to the incapacity of the nephritic patient to deal with increase of the water ingested. These authors consider the inability of the kidney to deal with increased amounts of fluid, as evidenced by the insufficient increase of diuresis and diminution of molecular concentration, to be an almost constant phenomenon in cases of parenchymatous nephritis. Cases occur in which the kidney shows an ability to deal with increased ingestion of water hardly below that of the normal kidney, and v. Noorden³ has shown that in such cases, in spite of their efficiency in this direction, there may be a well-marked oedema. Though oedema must be, of course, an expression of the retention of water, such retention may occur in spite of the ability of the diseased kidney to deal with an increase of water ingestion as efficiently as the normal one. A survey of the charts of this patient during the several weeks preceding the crisis gave no indication of considerable inability to deal with the slight increases of ingested water that had occurred during the course of his dietary, and, in order to set the question at rest, it was decided a month after the occurrence of the crisis to subject him to the *verdünnungsversuch* of Kovesi and Röth-Schulz.

A case of syphilitic nervous disease with normal kidneys and of about the same weight was selected for comparison and investigated by one of us (F. L. G.). The results are summarized in the following table:

	Normal.	Nephritis.
8 to 12 a.m.	70 c.cm. passed; Δ 2.05	115 c.cm.; Δ 1.75
1 to 2.30 p.m.	Given 1,200 c.cm. soda water	200 c.cm.; Δ 0.75
3.15 p.m.	160 c.cm. passed; Δ 0.80	200 c.cm.; Δ 0.75
4.15 p.m.	201 c.cm. passed; Δ 0.64	120 c.cm.; Δ 0.8
5 p.m.	150 c.cm. passed; Δ 0.15	94 c.cm.; Δ 0.12

Δ = freezing point of urine. After about three hours diuresis ceases.

The mean results show that in this case of nephritis there appeared to be no incapacity to deal with a large increase of ingested fluid. In both cases, when the mean nitrogen excretion was taken on days when the total fluid diet was 700 c.cm., and on a day when the fluid was increased to 2,300 c.cm., there was an increase of the total

nitrogen and chlorides during the period of diuresis. In the case of the normal man the nitrogen increase was 5 per cent., and the chlorides 2 per cent., and in the case of nephritis the nitrogen increase was 7 per cent. and the chlorides 3 per cent. It is therefore possible that the absence of an equivalent diminution of the freezing point in Kövesi and Röth-Schulz results was due to the washing out of retained products of excretion in the nephritic cases.

A case like the one recorded here would apparently offer an argument against the attempts to reduce oedema by decrease in the ingested water, and indeed there would appear to be much to be said in favour of Strauss's view that such a decrease may be dangerous. If the retention of water be not due to the inability of the kidney to excrete it—and this seems to be proved in this case by the fact that the increased water excretion was effected to a great extent by the skin—such a retention is probably a response to the increased osmotic tension of the tissues due to retained products of excretion. It is not enough to show, as v. Noorden and his pupils¹ have done, that the excretion of solids is not impaired by restricting the water given, we may still be depriving the organism of the protective mechanism by which the retained solids are prevented from disturbing the normal condition of the tissue cells, and such treatment may precipitate the onset of uraemia.

As to the cause of onset of these urinary crises when both kidneys and skin glands suddenly pour out the retained fluid, we are still in the dark. It is obviously of great importance that in such cases there should be records of the elimination of the nitrogen and salts both before and during the crisis.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

IODINE FOR STERILIZATION OF THE SKIN OF OPERATION AREAS.

THAT the importance of this subject is fully recognized by most operating surgeons is well shown by the numerous methods which are practised, and which need not be enumerated.

They are based on the knowledge that germs of various kinds lurk in the depths of the true skin, as well as superficially, and that they have an unhappy tendency to sweat on to the surface during the operation, and to infect the wound. The amount of labour expended on attempts to sterilize the operation area is very great, and the consumption of material correspondingly large. Occasionally, owing to "over-preparation," eczema results. For military or naval surgeons it is important to secure some method which is certain, rapid, and capable of being effected with a minimum of assistance and materials. For emergency work in private practice the method which I am about to advocate would be very useful. It consists in the use of a 10 per cent. spirituous solution of iodine. The idea is not in any way original, for I first learnt of it from a note of a paper by Dr. A. Grossich, of Fiume, in the *EPITOME OF THE BRITISH MEDICAL JOURNAL*, of November 21st, 1908. Since that date the whole of my operation cases have been prepared as follows:

The evening previous to operation the patient has a hot bath, using plenty of soap, but excessive scrubbing of the operation area is not permitted. It is then shaved, washed, and a piece of dry lint bandaged on. Nothing more is done until the patient is on the table. If eucaine is being used the area is *freely* painted with 10 per cent. spirituous solution of iodine (practically the liniment) and the eucaine injected. Before making the skin incision the area is painted once more. In the case of a general anaesthetic the iodine is painted before the administration is begun, and again when the patient is ready.

Preliminary scrubbing and wetting is not desirable, for Grossich points out that the superficial layer of the epidermis is not an absolutely compact tissue. The cells are loosely packed, and intercellular spaces exist which communicate with the external air by microscopic clefts. These clefts, which contain fat, sweat, and bacteria, are readily penetrated by an alcoholic solution of iodine, which dissolves their contents. On the other hand, in the method of cleansing commonly practised these clefts are likely to be closed by the swelling of the cells which is caused by hot water; or their contents may be retained by water and microscopic fragments of soap. For these reasons it is much more difficult to disinfect the skin by liniment of iodine after it has been cleansed by soap and water than if it had not been so cleansed and is quite dry. At the end of the operation the sutures are painted.

The following operations have been performed under this method: Appendectomy, radical cures of hernia and varicocele, hammer-toe. In every case healing by first intention has resulted. The number of operations—30 in all—is not great, but it enables me to state that I have obtained just as good results from using this very simple method as when I had the skin prepared the day before and again on the table, using turpentine, ether, soap, and mercury biniodide. The labour involved is enormously diminished, and a great saving of material is effected.

The potency of iodine as a sterilizer of such septic material as catgut is now well known, and it is only reasonable to expect just as good results in the sterilization of the skin.

Major, R.A.M.C.

Colchester.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF THE BRITISH EMPIRE.

WESTERN INFIRMARY, GLASGOW.

(Notes of cases under the care of Dr. J. CRAWFORD RENTON.)

1. Gastro-enterostomy and Pylorotomy.

J. M., sailor, aged 62, was sent to me by Dr. Whitehouse, suffering from dilatation of the stomach and an indefinite pyloric tumour. On opening the abdomen the tumour was found to be movable, with no evidence of disease of the liver. A small section of the tumour was cut out for examination. Gastro-enterostomy was performed. Professor Muir's report on the section was adeno-carcinoma. The patient recovered well from the first operation, and in three weeks pylorotomy was performed in the usual way. One or two glands were enlarged and were removed along with the others. The patient progressed favourably, and has gained 8 lb. since the operation two months ago.

2. Gastro-enterostomy for Duodenal Ulcer.

A. D., aged 35, was placed under my care by Professor Stockman. There had been severe haemorrhage in June when I first saw him with Professor Stockman, but his condition then was too serious to advise operation. The haemorrhage recurred in October, and he returned. Posterior gastro-enterostomy was performed (Mayo's method) and the duodenal ulcer blanket-stitched. He did well and has gone home.

3. Gastro-enterostomy for Ulcer of the Stomach.

M. A., female, aged 37, was sent to me by Dr. Monie of Airdrie, with symptoms of ulcer and pyloric contraction. On opening the abdomen a large ulcer was seen to occupy the lesser curvature of the stomach, with so much induration around it that a pseudo-bourglass contraction existed. Gastro-enterostomy was performed posteriorly. The patient made a good recovery and has gone to the country.

4. Cholecystotomy for Gall Stones and Suppuration.

B. R., male, aged 19, was sent to me on account of intense pain over the gall-bladder region. On opening the abdomen the gall bladder was found full of pus. A stone the size of a hazel nut occupied the cystic duct, and, along with several others, was removed. The patient recovered.

It is so unusual to have gall stones in one so young that I think it right to record the case.

5. Cholecystotomy for Gall Stones and Suppuration.

Dr. William MacLennan asked me to see L. C., aged 28, complaining of intense pain in the gall-bladder region, with high temperature, and, in addition, severe pain in the right thigh. There was no evidence of any swelling in the thigh, and the pain appeared to be one of those reflected pains concerning which Dr. MacKenzie of London has written so ably. The abdomen was opened, and the gall bladder was found full of pus; seven stones were removed. On recovering from the anaesthetic the first remark the patient made was, "The pain in my leg is quite away." The gall bladder was drained in the usual way, and she is now quite well.

6. Kraske's Operation for Epithelioma of the Rectum.

P. D., aged 21, came under my care for epithelioma affecting the middle part of the rectum. Kraske's operation was performed, the sphincter being retained. The patient recovered without any fistula.

Two cases operated on three years ago remain quite well. I still think favourably of this operation in suitable cases. Unfortunately patients do not come early enough.

7. Excision of the Knee-joint for Rheumatoid Arthritis.

M. P., female, aged 34, the subject of general rheumatoid arthritis, was placed under my care by Professor Stockman, as the knee-joint had become fixed at a right angle. An x-ray examination showed spikes on the femur and tibia in various directions. Excision of the knee-joint was performed, and the patient is now walking about free from pain.

8. Appendix Cases.

While continuing to be satisfied with the Fowler position, along with saline infusion into the bowel in cases of gangrenous appendix with abscess, as also in general peritonitis, I think we have helped eight bad cases recently by using a double dose of antistreptococcic serum into the rectum, which is repeated if necessary.

9. Laminectomy for Pott's Disease.

Two cases were noted in the BRITISH MEDICAL JOURNAL, one three and a half years ago, the other eighteen months ago. An opportunity was afforded recently of hearing of them, and it is satisfactory to record that they are both quite well. The laminectomy was only performed after all other means had been used.

10. Hysterectomy for Fibroid (Chorion-Epithelioma?).

A. F., aged 44, was sent to my care by Dr. Haldane, of Bridge of Allan. She gave a history of considerable haemorrhage. I advised operation, and hysterectomy was performed in the usual way. The appearance of the tumour led me to request an examination by Professor Muir and Dr. Teacher. Their report is as follows:

The uterus proves to contain the remains of a hydatidiform mole. There is the usual large amount of infiltration by trophoblastic elements, and there are large masses of trophoblastic cells (chorion-epithelial). While this is not absolutely diagnostic of chorion-epithelioma, it suggests very strongly that danger of development into this tumour was present.

THE General Association of French Medical Practitioners, which was founded on August 31st, 1858, will celebrate its jubilee in April, 1909.

An international congress for the amelioration of the condition of the blind will take place at Naples this spring. Questions relating to the training, education, work and rights of the blind will be discussed. Arrangements have been made for a joint meeting with the Congress of Ophthalmology, which is to be held at Naples at the same time.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Friday, January 22nd, 1909.

J. PORTER PARKINSON, M.D., in the Chair.

Rheumatoid Arthritis.

THE CHAIRMAN showed a case of rheumatoid arthritis in a young child.

Dorothy G., aged 2½ years, began to suffer from swollen and painful joints in June 1908; the ankles and wrists were first affected, then the knees, elbows, and other joints. There was much pararticular swelling, with excess of fluid in the joints. The joints were at times acutely painful, and the temperature rose occasionally to 103° or 104°. There was much wasting, and the child had a pallid earthy tint of skin, and appeared to be suffering from a slow toxæmia. There was general enlargement of the lymphatic glands, especially in the axillae and groins. The spleen was much enlarged, extending four finger-breadths below the costal margin. Over parts of the trunk and legs was a diffuse brown pigmentation resembling that seen in adults suffering from the same disease. The lungs and heart were normal. There was extreme wasting of the muscles of the legs and forearms. Intervals of pyrexia alternated with fever, often up to 103° F. or higher, lasting for a week or so, during which the joint pains and swelling, the lymphatic and splenic enlargements, and the cachexia were all much increased.

There had been great improvement during the last six weeks both in the general and local symptoms.

Dr. MILNER BURGESS said he thought the name "rheumatic" should be dropped in connexion with such cases, as it seemed to be the general opinion that there was no relation to rheumatism.

Dr. E. I. SPRIGGS said that occasionally, on seeing a case for the first time, there seemed to be some difficulty in diagnosis between subacute or chronic rheumatism and rheumatoid arthritis, though that difficulty generally vanished when the case was carefully gone into. Recently he showed before the Clinical Section an adult male with true rheumatoid arthritis who had enlarged glands in the groin, axilla, and above the elbow; he also had exophthalmic goitre. In the latter disease there was frequently pigmentation, and in chronic infective arthritis in adults. Exophthalmos had also been described in connexion with Still's disease, though he had never seen it. The spleen was probably enlarged in children because that organ responded more easily to infective conditions in them than in adults. He mentioned a case like that of Dr. Parkinson's in which material had been obtained from the joint, but efforts to cultivate a micro-organism were fruitless.

Dr. PARKES WEBER asked whether von Pirquet's reaction for tubercle had been tried.

Dr. PARKINSON replied that he used the term "rheumatoid," and agreed that such cases should not be called "rheumatic." Dr. Spriggs's case of rheumatoid arthritis in which glands were enlarged was interesting in showing the link between the cases in children and in adults. He did not think the case was tuberculous, but would try the reaction.

Congenital Cystic Disease of Kidneys.

Dr. T. R. WHITFAM showed a specimen from a case of congenital cystic disease of the kidneys, and a skiagram taken during life. Both kidneys were from a male infant, aged 11 months, who was brought up for whooping-cough and found to have an enlarged abdomen with bulging in both flanks and some dilated superficial veins. Two masses could be felt symmetrically situated, and the anterior edges extended from the costal margin to the middle of Poupart's ligament. The tumours were slightly movable, and the percussion note over them was dull. The liver could be felt 1½ in. below the costal margin. The abdomen had been noticed to be large since birth. The specific gravity of the urine varied from 1005 to 1010. The urine contained a varying amount of albumen, from 0.1 to 0.8 per cent. The quantity of urea was from 0.4 to 1.8 per cent., the total being from 1.05 to 3.12 grams per diem. The child, who was not greatly troubled by the cough, became rapidly worse. A transient oedema of the hands

and feet occurred for a few days, and towards the end the liver became enlarged and some purpuric spots appeared on the trunk. Death was ushered in by convulsions. The kidneys weighed 7½ oz each. They were uniformly pale and tough, and showed little difference between the cortex and medulla. They were crowded with innumerable cysts, the largest being the size of a very small pea. The capsules were somewhat adherent. The pelvis were dilated and contained a deposit of uric acid sand, but the ureters were normal and there was no obstruction to the flow of urine.

Dr. PARKES WEBER congratulated Dr. Whiplam on having diagnosed the condition during life. In his opinion, however, congenital cystic disease was not the only disease which might give rise to enlargement of both kidneys and albuminous urine in a child. He had published a case which showed diffuse lymphocytic growth of both kidneys.

Dr. ROBERT HUTTON asked whether congenital cystic kidneys were ever unilateral, as he had made such a diagnosis in an adult case. He could recall two other cases in which the diagnosis was made during life. If a nodulated tumour could be felt in both loins and there was suspicious urine he thought the diagnosis was justified.

Dr. CAUTLEY said he thought the diagnosis could be justified if only one kidney was felt, as there were several cases on record in which one kidney showed signs and the other was found *post mortem* to be also cystic.

Dr. FORSYTH quoted a case in which two enormous cystic kidneys were found *post mortem*, but only one had been felt.

Fibrosis of Lung.

Dr. JEX BLAKE showed a case of fibrosis of the left lung of considerable standing in a child aged 8 years.

There was a history of phthisis on both sides of the family. The patient had whooping-cough at 12 months, and "pneumonia" at 4; no other illnesses. At 5 he was admitted in April, 1906, to St. George's Hospital with fibrosis of the left upper lobe and bronchitis; while in hospital he showed irregular fever, 99° to 101° every evening. In January, 1908, he was admitted to the Victoria Hospital with the complaint of cough and wasting; the signs of fibrosis at the left apex were more marked, and there was slight clubbing of the finger tips. While in hospital he coughed little, and no sputum could be collected; the temperature was irregular, rising occasionally to 99° to 100°.

On January 12th, 1909, he was brought to the hospital again, with a history of cough and general illness for one week.

No sputum had been obtained since he had been in hospital.

The x-ray examination showed general opacity of the upper part of the left lung; the heart was drawn over to the left; the diaphragm was low, and moved poorly on both sides.

The chief point of interest about the case was that on admission it showed Grocco's paravertebral triangle of dullness on the right side behind.

The CHAIRMAN asked the opinion of members on the value of Grocco's triangular dullness. He believed the sign to be present in this case, but some had said that it was present in every child whether healthy or diseased.

Dr. EWART said that in his hands the Grocco sign had been valuable as a sign of fluid, but it was, of course, necessary to exclude the presence of dullness from consolidation. The crucial test was to change the position of the patient, and if the fluid was free the triangular dullness should disappear, and should return on restoring the body to the former position. Empyema, not being commonly free, did not answer to this test. When fluid filled the peritoneal cavity and raised the diaphragm, Grocco's sign could be found as a big equilateral triangle bisected by the spine.

Infant Mortality as Seen in a Children's Hospital.

Dr. DAVID FORSYTH read a paper on Infant Mortality as seen in a Children's Hospital. An exact pathological knowledge of the causes of infants' deaths was of the greatest practical importance from the point of view of prevention. Hitherto our principal guide in this matter had been the official returns of the Registrar-General, which showed the relative importance of various diseases in this connexion. These returns, however, were in some cases difficult to harmonize with the experience in the wards and *post-mortem* room of a children's hospital. Conditions known to be frequent causes of death in hospital practice occupied a relatively insignificant place in the official returns, whilst others which were officially important were in practice unimportant. With the object

of obtaining statistics based on accurate death certification, Dr. Forsyth had examined the death records of the Evelina Hospital for Sick Children from January 1st, 1885, to December 31st, 1906, and had analysed the causes of 1,202 consecutive infant deaths under one year. The numbers in this series were as follows:

Acute lung diseases, 254; diarrhoea, 188; whooping-cough, 135; tubercle, 128; marasmus, 78; congenital defects, 75; syphilis, 55; septic conditions, 44; intussusception, 34; mastoid disease, 32; meningitis (non-tuberculous), 26; rickets, 13; convulsions, 13; all other diseases, 127. Total, 1,202.

The method adopted in tabulating these cases was explained, and reasons were given to show that a comparison with the returns for England and Wales was permissible. For reasons specified, the three items—prematurity, measles, and whooping-cough—were excluded from the comparison. Under the remaining headings, the mortality in the official and in the Evelina Hospital returns stood thus in percentages:

	Evelina Hospital.	England and Wales.
Acute lung diseases	23.8	21.40
Diarrhoea	17.6	23.30
Tubercle	12.0	5.10
Marasmus	7.3	16.30
Congenital defects	7.0	6.50
Syphilis	5.2	1.50
Septic conditions	4.1	—
Intussusception	3.2	—
Mastoid disease	3.0	—
Meningitis (non-tuberculous)	2.4	2.00
Rickets	1.2	0.59
Convulsions	1.2	12.20
Injury at birth	—	0.75
Starvation	—	0.70
Other causes	12.0	10.16
	133.0	100.00

Whilst a fairly close correspondence existed between the two series, many striking differences must be noticed. Acute lung trouble and congenital defects showed no great divergences. With diarrhoea, the somewhat smaller figure that represented the Evelina Hospital mortality was accounted for by two facts. In the summer, when diarrhoea was rampant, the accommodation in children's hospitals was overtaxed, and even moribund cases might be sent away. Secondly, it was probable that some of the deaths in the official returns which had been ascribed to diarrhoea would have been registered under other headings if facilities for *post-mortem* examinations were as great in general practice as in hospitals. With regard to marasmus, a difference of more than 100 per cent. existed between the two series of figures. Since the official returns represented over 15,000 dead infants, its interpretation possessed wide practical importance. Marasmus was a term of vague significance, and was often employed in connexion with diseases of which it was merely a symptom, especially with syphilis, improper feeding, and tubercle. It could not be doubted that deaths from these causes were sometimes registered as due to marasmus, and that a proportion of them should be distributed under other headings. These criticisms applied even more forcibly to deaths from "convulsions," the official returns for which were no less than 1,000 per cent. of the Evelina figures, and represented 11,000 deaths. The term "convulsions" under no circumstances represented more than a symptom, and when employed as a cause of death merely hid under a meaningless designation important fatal conditions, the returns for which were unduly minimized. With regard to syphilis, this disease was held responsible in 1905 for only 1,200 infant deaths in the whole of England and Wales—little more than 3 a day. In the same year, however, 19,000 infants under 2 months were

stated to have died from prematurity. Probably this large figure included the deaths of numbers of syphilitic infants. As a matter of fact, the deaths in 1905 from syphilis of infants under 3 months amounted only to 300 according to the official returns. Other deaths from this cause must be looked for under the heading "marasmus." With regard to rickets, the hospital figures were twice those for England and Wales. Here it must be remembered that cases of rickets were often fatal from bronchopneumonia or diarrhoea, and the primary condition was likely to be overlooked. After referring to acute mastoid disease as a cause of infant mortality, Dr. Forsyth passed to the question of tubercle. The Evelina Hospital figures included only those cases in which tubercle was the actual cause of death, and excluded all in which, though a tuberculous lesion was found *post mortem*, death resulted from some other cause. The difference in the two series was probably to be explained by the tendency of tuberculous disease in infants to simulate other non-tuberculous affections. Probably the hospital figure, 12 per cent., more nearly represented the real mortality than the official figure, 5 per cent. The frequency, however, with which life was destroyed by tuberculous infections incurred during infancy was underestimated even by this larger number, because many such cases did not die until their second year, and their deaths did not come into the infant mortality returns. The full importance of tubercle as a factor in infant life would be better revealed by statistics dealing with deaths up to 15 or even 18 months. At the Evelina Hospital 50 children died of tubercle between these ages. Many, if not most of them, must have been infected during their first year. In conclusion, Dr. Forsyth expressed the hope that these Evelina Hospital statistics would lead to the preparation of corresponding figures from the records of other children's hospitals. An accurate knowledge of the causes of infant mortality could be best obtained from those institutions in which special opportunities existed for ascertaining the exact causes of infant deaths. If, further, the absolute numbers in each series were published, they would be in a position to draw valuable conclusions based on many thousands of cases. At present 20 per cent. of the mortality, representing 25,000 deaths, was attributed to vague symptoms. When the community had set a proper value on infant life, such terms as "convulsions" and "wasting" would no longer be accepted for death registration. If no more satisfactory explanation of the cause of death were forthcoming further steps would be insisted on, as was done to-day with adult deaths. By this means a far-reaching and practical measure would be taken to diminish the present excessive waste of infant life.

The CHAIRMAN said the Section was much indebted to Dr. Forsyth. He commented on the few deaths attributed to rickets being put under the heading of the terminal trouble, whatever it might be.

Dr. DUDFIELD said that Dr. Forsyth had shown a classification of deaths on a strictly scientific principle, which could not be said for the Registrar-General's classification. The Registrar-General's rule that if the duration of the disease was not mentioned on the death certificate the first disease on the list should be taken as the cause of death led to some curious results. For instance, syncope would be mentioned first and diabetes second. In a case of bronchopneumonia or tubercle and whooping-cough, whooping-cough was usually selected for the cause of death. "Marasmus" was a very favourite term with the profession.

Dr. HUTCHISON expressed surprise that mastoid disease was responsible for 3 per cent. of the deaths. He did not think that this would be found to be the case at the Great Ormond Street Hospital. Might it be due to the large amount of whooping-cough treated at the Evelina?

Dr. MEREDITH RICHARDS said that marasmic children admitted to hospital would have proper treatment and many of them would recover; whereas, if they were not admitted to hospital, death was more likely to occur. In tubercle also there was a large amount of selection. Therefore, it was necessary to take precautions when comparing hospital figures with those gleaned from the community in general.

Dr. W. EWART said that a *post-mortem* basis seemed to

be the only reliable scientific one. The difference in statistics from a hospital and those from sources remote from hospitals was an index of the progress of medical science.

Dr. CAUTLEY, after congratulating Dr. Forsyth on his energy in regard to the paper, went on to say that the conditions of hospital practice were so different from those in everyday life that he doubted the applicability of the results. He would have liked to have known the ages or the mean age of the cases.

Dr. FORSYTH, in reply, said that it was from the scientific aspect that he regarded the figures. The methods adopted in tabulating death registration were different from those in a hospital. He understood from Dr. Duffield that if a child died from septic meningitis or mastoid disease twelve months after having suffered from scarlet fever, the death was attributed to scarlet fever. That was misleading. Another point was that his statistics were taken over a period of twenty-three years. Twenty-three years ago the death-rate from mastoid disease was probably much higher than now, and no doubt now it was less than 3 per cent. He had tried to show that a diagnosis on clinical data was not always a true one, *post-mortem* examination giving the most accurate figures.

OBSTETRICAL AND GYNAECOLOGICAL SECTION

Thursday, January 14th, 1909.

HERBERT SPENCER, M.D., President, in the Chair.

Histology of the Smaller Myomata.

Dr. FLORENCE E. WILLEY read a paper on this subject. She said sections of young myomata, from 5 mm. diameter upwards, illustrated the following points:

1. That the proliferating cells in growing tumours were muscle cells.

In sections from patients, aged 30 to 40, with enlarging uteri, the areas of proliferation showed less connective tissue in proportion to the muscle than was found in non-proliferating muscle bundles of the same uterine wall, and the muscle nuclei were oval to rod-shaped; whereas seedling tumours past the menopause consisted largely of fibrous tissue, and the muscle cells had narrow rod-shaped nuclei.

2. The cells which proliferate were not those of the vascular system, but cells common to the whole uterine parenchyma.

3. The shape of early growths was most various, depending on the direction of the muscle bundles concerned rather than on any relation to vessels, large or small. Capsule formation began later, when the growing tumour assumed an oval or spherical shape.

4. Subperitoneal fibromyomata often began by proliferation of the muscle bundles immediately beneath the peritoneum, and capsule formation in these was first seen on the site adjoining the uterine wall.

5. In sections of sixty to seventy uteri of all ages no fibromatous seedling had been found before puberty, and those in women past the menopause consisted largely of fibrous tissue.

The author concluded that fibromyomata arose as irregular patches of proliferation of muscle cells of the uterine parenchyma, which had no special relation to the vascular system. The cause of this proliferation was unknown, but the absence of growing tumours before puberty and after the menopause suggested some relation to the activity of the sexual organs.

The PRESIDENT corroborated Mrs. Willey's statements as to the absence of capsules in many small fibroids, and had been surprised to hear it asserted that they always had capsules.

After remarks by Dr. HEYWOOD SMITH and Dr. MACNAUGHTON-JONES, Mrs. WILLEY replied.

Remote Results of Abdominal Hysterectomy.

Mrs. STANLEY BOYD gave the remote results and *post-mortem* findings four and a half years after operation in a case of abdominal hysterectomy for cancer of the cervix, followed by vesico-vaginal fistula. Vesico-vaginal fistula developed six days after the operation, but was small, and gave the patient comparatively slight inconvenience, so that she persistently declined operation for its closure. The case was watched for four and a half years, during which time there were intermittent attacks of pyuria, which were attributed to suppuration in the neighbourhood of the bladder bursting into it. In August, 1908, the patient was admitted into the Great Northern

Hospital with suppuration about the right kidney, under Mr. Peyton Beale, too ill for anything but incision of abscesses and palliative treatment. She died September 12th, 1908. The *post-mortem* examination showed no recurrence of growth, but complete occlusion of the right ureter at its vesical end, where it was embedded in a mass of cicatricial tissue, right pyonephrosis, perinephric suppuration, subdiaphragmatic abscess, and right empyema.

The PRESIDENT said he had often wondered what happened to patients with ureteral fistulae when the fistulae closed, as Wertheim had shown that they frequently did, and whether the extensive removal of the tissues around the ureters might not lead to cicatricial obstruction of these tubes.

Dr. A. H. LEWERS said that he had had a case of vaginal hysterectomy for carcinoma of the body of the uterus many years ago, in which a ureteral fistula had developed. Nothing of an active kind was done for it, and some months later the fistula healed. The patient was seen several times subsequently, and there was no evidence of anything wrong with the kidney.

Dr. G. F. BLACKER had had three cases of ureteral fistula occurring after total abdominal hysterectomy. In the first case, owing to septic changes, the corresponding kidney had to be removed, and this was followed by complete recovery. The second case developed an attack of acute suppression of urine, lasting twenty-four hours, about five weeks after the operation. The patient recovered and the fistula healed. In the third case the patient developed a high temperature a month after the operation, and the *Bacillus coli* was found in the urine. Eight weeks after the original operation the patient died with symptoms of pyaemia, and at the *post-mortem* examination a small abscess was found at the site of the fistula.

Mrs. STANLEY BOYD replied.

The Role of the Perineal Body in Labour.

Dr. R. H. PARAMORE read a paper on the rôle of the perineal body in labour. He stated that the perineal body played no part in the support of the viscera, nor did its rupture facilitate prolapse. Yet the perineal body exercised a far-reaching influence during childbirth which was neither necessary nor good. In the descent of the fetal head through the outlet of the pelvis, the pelvic floor became transformed into a broad, gutter-like declivity, at the lower end of which the posterior commissure of the pubo-rectalis muscle is found. The dilatation of the anus and the increase in length of the base of the perineal body showed how much the tissues below the pelvic floor stretched. The tension of these thinned-out peritoneal tissues determined the more forward projection of the anterior segment of the head, the head being ovoid in shape. If the vulvar aperture was destroyed by a laceration, the movement forward of the anterior segment of the head did not occur. It was evident that a perineal tear, by allowing birth with the least possible distension of the muscle, might undoubtedly in many cases prevent an injury which predisposed to prolapse. An early peritoneal tear might be a blessing in disguise. Perineal tears, when they did not involve the sphincter, were trifling injuries, and the only reasons for suturing them were to check haemorrhage and prevent infection. The main mass of the pelvic floor musculature passed behind the anal canal and remained intact, in spite of such a tear. The continued extension of the head could be prevented by adopting the method of Toff. When the head appeared at the vulva, two fingers were placed between it and the pubes, and traction exerted backwards. Simultaneously the head might be pressed downwards and forwards from above the anus.

Dr. MACNAUGHTON-JONES said he would be sorry to think that it should go out from this Section that there should be any divergence from the obstetrical rule of at once closing a perineal tear. Rectocele and vesicocele constantly occurred with what Howard Kelly called "relaxed vaginal outlet," where there was no apparent laceration, but in which the perineum was weakened.

Dr. AMAND ROUTH thought that there could be no possibility of doubt that the perineal body serves many useful purposes, and that its integrity was essential to the

preservation of the tone of the vaginal and vulvar outlet.

LARYNGOLOGICAL SECTION.

At a meeting held on January 8th, Dr. DUNDAS GRANT, President, in the chair, a discussion took place on the *Modern treatment of syphilis*, especially with regard to the upper respiratory tract. Dr. LIEVEN (Aix-la-Chapelle), who opened the discussion, referred to the recent advances in syphilology, including the identification of the *Spirochaeta pallida* and the detection of specific antibodies in the serum of people infected with syphilis. No serum-therapeutic treatment had, however, been found effective. The chief remedies were still mercury and iodides. Mercury had been proved by Neisser, by experiments on anthropoid apes, to assist the organism to defend itself against the spirochaete, and also to kill the microbe. Atoxyl was found experimentally to produce the same results, but if given in sufficiently large doses to be effective it was dangerous to the optic nerve. In the administration of mercury Dr. Lieven advocated inunction and subcutaneous or intramuscular injection, and compared the advantages of soluble and insoluble salts for injection. His preference was for calomel as far as effectiveness was concerned, but he reserved it for the malignant forms, the salicylate being more suitable for routine treatment. These salts should be avoided in cases of Bright's disease or diabetes. Inunction was better tolerated if combined with baths of soap and sulphur. The secretions of the sebaceous and sweat glands rendered it capable of being absorbed and of circulating in the body as an albuminate. Stomatitis was best combated by brushing the teeth after each meal with a paste of salol and chlorate of potash, and by rinsing the mouth every hour with a solution of aceto-tartrate of aluminium. Iodides were most useful in tertiary manifestations, but were also effective against secondary vegetating patches at the entrance of the nasal passages and on the floor of the nose. Iodism was often removed by the daily administration of 15 grains of sulphuric acid in 7 oz. of water. Iodipin might be substituted for those who were very sensitive to iodides. Dr. Lieven thought that there was not yet sufficient evidence in favour of treatment by means of the various arsenic preparations. Before treatment was commenced the diagnosis should be certain, and in doubtful cases the spirochaetes should be found, or time should be given for the serum test or the appearance of a roseola. Inunctions or injections should then be given, in most cases no local treatment being necessary. Chancres on the lips or face might be covered with mercurial plaster; those inside the nose or mouth should not be cauterized, simply dusted with nasophen, or, for pain, orthoform. Secondary ulcerative patches might be painted with a concentrated solution of chromic acid, and over this a 10 per cent. solution of silver nitrate to form an adhesive scab. At the end of the first year iodides were given. After the healing of tertiary lesions under the iodide of potassium (the most rapid remedy) iodipin injections together with mercurial inunctions were useful. Colonel LAMBRIN, R.A.M.C., considered inunction to be the ideal remedy, but difficult to carry out in practice. He therefore made use of injections, and he started usually with $\frac{1}{2}$ grain of calomel once a week for four weeks, and then continued with metallic mercury. He favoured local treatment in the upper respiratory passages by means of chromic acid and even curetting. He had treated about 120 cases with arsenic, and had found less soreness of the throat, but since his observations in Uganda, he had given up atoxyl. Sir FELIX SEMON considered the oral administration of mercury no preventive of severe tertiary manifestations. Local applications were needless, and malignant cases should be treated with calomel injections and with sarsaparilla rather than with iodides. Major FRENCH, R.A.M.C., commenced treatment with inunctions, and afterwards injected grey oil. He always stopped smoking during treatment. Dr. BENDORS favoured administration by the mouth. He spoke well of injections and of Zittmann's decoction, in which the mercury was in the form of an albuminate. Mr. BAKWELL used injections of mercuric benzoate and inunctions. Dr. DONELAN advocated inunctions, then mercury and iodides, and then inunctions again. The discussion was continued by Mr. STUART LOW, Dr. STCLAIR THOMSON, Dr. SCANES SPICER, and the PRESIDENT; and Dr. LIEVEN replied.

MEDICAL SOCIETY OF LONDON.

Monday, February 1st, 1909.

CHARLES BARRETT LOCKWOOD, F.R.C.S., President,
in the Chair.*Functional Disorders of the Stomach.*

DR. SIDNEY MARTIN delivered the first of the Lettsomian Lectures for 1909. He divided functional disease of the stomach into three groups: (a) Gastric irritation, in which the symptoms were induced mainly through irritation of the organ from various causes; (b) gastric deficiency, which might result from irritation of the organ, and in which the main condition was that of deficiency of the function of the stomach; (c) indigestion of nervous origin in which symptoms referable to the stomach were associated with a large number of symptoms referable to the nervous system. The term "gastritis" ought to be reserved for inflammation of the stomach, which might occur in various diseases or as a result of an irritant poisoning, and such cases he did not propose to consider. Reference would be made to organic disease—ulcer and carcinoma—of the stomach. The digestive activity of the stomach contents (that was the amount of pepsin secreted) increased or diminished with the amount of hydrochloric acid secreted by the mucous membrane. In the ordinary forms of gastric irritation which were commonly described as acid dyspepsia there was hyperchlorhydria. The percentage of hydrochloric acid secreted two hours after a meal was between 0.25 and 0.4 grams. That was an undoubted fact, which he could verify not only from his own observations but from those which had been made on a large scale in other countries. In functional cases, such as were admitted into the wards of a hospital, in which there were severe symptoms and usually grave defects of nutrition, it was found that the condition was more frequently one of hypochlorhydria than of increased secretion of acid. All the cases recorded were diagnosed as functional, partly from the duration of the illness, partly from the symptoms, but mainly from the fact that recovery occurred more or less completely as a result of treatment. He had records of 25 cases; in one case there was no secretion of acid in two hours' digestion; in 4 cases the total acid secreted was under 0.1 per cent.; in 7 cases the secretion was from 0.11 to 0.14, and in the remaining 14 cases the secretion was either normal or (in 4) was increased. A large proportion of the cases showed a great deficiency of gastric secretory activity. Of the 7 cases of neurosis, 1 showed achlorhydria, 2 a percentage of 0.12, 1 of 0.2, 1 of 0.24, and 2 of 0.29 hydrochloric acid. All those were cases of indigestion of food, with great predominance of nervous symptoms, and the gastric analyses showed the great variations which occurred in the secretion of acid in such cases; 16 of the other cases were definite instances of damage to the stomach by irritation of various kinds. In 2 cases there was marked increase in the amount of acid secreted. In 7 the percentage of acid was between 0.18 and 0.23. In 3 the percentage was about 0.12, and in 4 the percentage varied between 0.02 and 0.03. These cases might, therefore, be divided as regards the secretion into 7 of hypochlorhydria, 7 of normal secretion, and 2 of hyperchlorhydria. In the case of achlorhydria, after three weeks' treatment a fair percentage of acid was found in the stomach contents, and in 2 other cases a similar result was obtained. In another case, however, the percentage of acid was actually less after a month's treatment, although that patient eventually was to all intents and purposes restored to health. The 2 cases remaining were those of gastroparesis, both occurring in women. One showed a diminished percentage of acid, 0.12; the other showed a slight increase (0.23). At the time cases came under treatment there was great variability in the secretion of acid in the stomach, so that it was impossible solely from the symptoms to determine whether the case was one of increased acid secretion, diminished acid secretion or absence of acid secretion. The digestive power was fairly proportional to the amount of acid secreted, but even when some acid was secreted no pepsin might be present in the stomach contents. Organic acid was absent in nearly all those cases that showed an acidity of over 0.2 per cent., below that percentage of acid organic acids were found, chiefly

lactic acid, in small quantities, although in one case it was 0.14 per cent. Two of those cases were of the nervous type, in one the secretion of acid was 0.21 per cent., and in the other, a case of neurotic vomiting in a young girl, it was 0.29 per cent. Dr. Martin then gave details of 18 cases of ulcer of the stomach. Of these 5 showed a deficiency of 0.1 per cent. and under; the remaining 13 cases were either slightly below normal or more than the normal, that was, they showed hyperchlorhydria. He drew attention to one case in which three years after gastro-enterostomy the secretion of acid was 0.14 per cent., and the digestive power was 54 per cent., both below the normal. He would speak later of the condition of the stomach after gastro-enterostomy and ulcer, and draw attention to the fact that not only might there be deficiency in secretion, but also from time to time an increase of secretion. Dealing with a series of 18 cases of carcinoma, he considered that they contrasted strongly with cases of ulcer and cases of functional disease, inasmuch as the greater proportion showed a great diminution of acid secreted as well as a great diminution of digestive power. In conclusion, Dr. Martin said his review of secretory activity in disease showed that the result of analysis of the stomach contents could not be relied upon as absolutely diagnostic.

OPHTHALMOLOGICAL SOCIETY OF THE
UNITED KINGDOM.

Thursday, January 28th, 1909.

R. MARCUS GUNN, F.R.C.S., President, in the Chair.

Hereditary Lamellar Cataract.

MR. BISHOP HARMAN read a paper on four generations of lamellar cataracts. He showed the pedigree of a family for five generations, four of which presented a marked inheritance of congenital cataract. Seventeen childships were traced, comprising 63 persons; 8 died in infancy; of the remaining 55 it was known that 19 had congenital cataract. In no case had there been any in-breeding, or marriage with a person similarly affected. The type of cataract was, for the most part, central opacities of varying size; some were minute, Y or X or star-shaped, others showed definite lamellar formation. In some cases the cataracts were of long standing, and no evidence could be found that they had progressed beyond the stage at which they were earliest seen. Probably the number of cases of cataract found did not represent the true total, for in one childship of seven members amongst whom only one case of cataract was admitted, examination of the seven showed that four had lenticular opacities. The inheritance was strictly from those who had cataract. In no case was cataract found in a child where the parents were free from the defect. When a defect had disappeared from a branch of the family it did not tend to reappear. The teeth usually were good, and no other developmental errors were found.

MR. HARMAN also read notes of a case of unusually rapid development of cataracts in a boy of 9 years. A year previously his vision had been recorded at school as $\frac{1}{20}$; an examination passed three months before showed that he could then write well. When seen he was quite blind; both lenses were completely cataractous; the lens matter was soft and opaque. The lenses were removed by curette evacuation at the Belgrave Hospital, and at the end of six weeks the boy left the hospital able to read $\frac{1}{20}$ with cataract glasses, and later on he saw $\frac{1}{10}$. He showed no trace of general disease, but there was some evidence of defect in his ciliary vessels.

Colours of Benham's Top.

MR. A. S. PERCIVAL (Newcastle-on-Tyne) read a paper entitled "Note on the Colours of Benham's Top," and demonstrated the different colours shown when the top was rotated clockwise as compared with those when the rotation was in the opposite direction. The explanation, which was not yet certain, was highly technical, and he suggested several theories.

Rhythmic Oscillations of Pupil.

MR. PERCIVAL also read a contribution entitled "Note on Some Rhythmic Oscillations of the Pupil." He said that all were familiar with the rhythmic contraction and

dilatation seen in certain diseases, and which were usually looked upon as of grave significance. He compared this with the oscillatory discharge from a Leyden jar which occurred under certain conditions. If it were discharged through a conductor of high resistance the charge simply died away. If it were discharged through a good conductor, such as a coil of wire, the discharge consisted of a number of excessively rapid oscillations or surges. He then compared the nerve cell and axis cylinder with the Leyden jar and conducting wire, stating that owing to disease the discharge of nerve impulse was made in an irregular manner. He regarded the movement tremors of disseminated sclerosis as an almost exact parallel to the oscillatory discharge of a Leyden jar.

Retinal Exudation.

Mr. DAVID J. WOOD (Capetown) sent a communication on a case of retinal exudation with extreme distension of vessels and perhaps arterio-venous anastomosis. He had contributed a similar case to the twelfth and another to the twenty-fifth volume of the society's *Transactions*, and recently he had seen and examined a third instance of this rare condition. He saw the patient first in 1902, and ordered glasses for her; there was then no complaint of the sight being bad. Later, as she had an attack of dimness of vision, he examined her fundi, and found large blood vessels running up to a patch on the upper part of the fundus, which possibly might have resulted from a former haemorrhage. The patient, who was then 50 years of age, returned in 1907, reporting that a few days previously the right eye had suddenly failed. He found that to be due to a diffusive opacity in the vitreous; no fundus details could be made out. Then the vitreous began to clear, and the drawing he showed represented the appearance seen. There was a white area above, and enormously dilated blood vessels could be seen running up to it from the disc. The colour of the vessels, which were very tortuous, was intermediate between that of arteries and veins. From the left trunk a vessel sprang which was arterial in colour, while another vessel, obviously venous, sprang from the opposite main trunk. There were fine choroido-retinal changes, which covered the inner part of the fundus. He thought the growth was probably sarcomatous, and his colleague advised excision, but he was so impressed with its likeness to his other cases that he held his hand. He hoped to report further on the case. He had not been able to hear more of his second case, already mentioned.

Mr. TREACHER COLLINS described a similar case, and remarked on the rarity of the condition; and Mr. G. COATES described the pathological findings in a case he had thoroughly examined.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Friday, January 15th, 1909.

W. G. SMITH, M.D., President, in the Chair.

A Year of Mental Hospital Work.

Dr. DAWSON read a short report of the more interesting points which had arisen in the practice of Farnham House Mental Hospital during the year ending March 31st, 1908. Of the admissions, the essential cause in 29.4 per cent. was diathesis, in 47 per cent. various forms of moral and physical wear and tear, and in 23.5 per cent. toxic influences; there was, however, a neuropathic heredity in 71.4 per cent. The forms of disease in the cases due chiefly to diathesis were mania, melancholia, and dementia, with two cases of alcoholism. In one of the cases belonging to the second class the cause appeared to have been relief of anxiety. Of the toxic cases, one of alcoholic paranoia was quoted as showing that some alcoholic cases exhibited no symptomatic pathognomonic of their origin. A case of true diabetic melancholia was also detailed, in which recovery occurred when the sugar disappeared. Amongst the admissions melancholia had been the prevailing form of disease. Albuminuria had been found in 12 cases, mostly of a depressed cast, glycosuria in 8. Arterial pressure was tested in 7 admissions, being found normal in 2, high in 5. A case was related which seemed to show that large doses of bromide may possibly lower resistance to micro-organisms. Thyroid treatment was tried in 7 cases, with good results in 3. Two, how-

ever, were not improved, and the state of the heart induced by the drug had given some anxiety for a time. Atropin treatment had been used in 2 cases of alcoholism with some immediate success, unsuccessfully in a case of morphinism. Suprarenal had been found useful in keeping excitement in check. Some advantage had been found in the use of formates and lecithin.

The PRESIDENT said that the discussion in that section last year had shown that the influence of alcoholism *per se* in the production of insanity had been overrated. He was anxious to know if there were any definite mental variations correlated in any way with the forms of alcoholism. It was said that the police of France found absinthe drunkards to be homicidal, and had to separate them from the others, and it was possible that the essential oils in absinthe were important in producing pathological results. He would also like to know if there was any particular type of mind, or mental development, that was specially predisposed to alcoholic disturbance.

Dr. KIRKPATRICK had some difficulty in understanding what Dr. Dawson meant by regarding diathesis apart from heredity in some of his figures. Did he recognize a type of individual who was likely to go mad apart from any hereditary taint? He thought there was a difficulty in accepting mental stress and strain as a general cause of insanity, although it might be a predisposing cause in conjunction with some weakness, hereditary or acquired.

Dr. DAWSON, in reply, said the correlation of alcoholism and mental affection did not appear to have been studied. He was strongly of opinion that any one who had a neurotic heredity or who had acquired it should abstain absolutely from alcohol. Melancholic and demented patients were liable to suffer more from glycosuria than others. There were very few cases of insanity in which there were not contributory and exciting causes, and his classification was only intended to embrace what he considered the predominating cause of the particular attack. Diathesis was probably always hereditary, but it was not possible in all cases to trace the heredity. He held diathesis to be a different thing from heredity. He had not had experience of cases due to eye strain.

Intracranial Tumour.

Dr. DRURY read the history of a case of intracranial tumour in a woman aged 30. Her symptoms had lasted for six months before she came under observation. When seen the cardinal symptoms of brain tumour were present, but there was nothing to indicate its position. As she was getting rapidly worse, unconsciousness impending and sight almost gone, an operation for relief of pressure was performed by Dr. Arthur Ball on July 13th, 1908. A large trephine opening was made in the temporal region on the right side under the muscle; the dura opened and a small quantity of fluid escaped; the wound then closed. Improvement followed rapidly; at intervals vomiting and headache returned, and the brain was tapped, fluid being drawn off on each occasion. These intervals became shorter, till eventually tapping had to be done daily. A tube was then inserted and kept in permanently for several weeks. During all that time very large quantities of fluid escaped. The patient improved so much that she could walk about, and could see and recognize people, and had neither headache nor vomiting. The wound was kept aseptic during the whole time. She suddenly became unconscious one morning, and died the next morning, November 8th, nearly five months after operation. The case was brought forward to illustrate the relief afforded by an operation of this kind, where there were no symptoms to indicate the position of the lesion, and, therefore, where no operation with any hope of cure could be attempted. It was found that the lesion was a large cyst in the cerebellar and pontine regions, which could not have been dealt with even had it been localized.

Polio-myelitis of the Conus Medullaris.

Dr. O'CARROLL reported a case. A girl, aged 17, had been sent up from the country suffering from "tumour of the bowel." This turned out to be a very big prolapse of the rectum. Some months previously she had had a febrile attack, following which she had suffered from incontinence of urine and faeces. Later the bowel prolapsed. The sphincter ani was entirely relaxed, and the opening of the urethra rather wide. Sensation was perfect. The patient's general health was good. Under

treatment, principally by the faradic current, complete control was recovered in the rectum, but the patient was unable to retain urine for more than two hours when she left hospital.

Reviews.

RADIOGRAPHY AND DIAGNOSIS.

THE long-anticipated *Manual of Practical X-Ray Work*,¹ of which Drs. ARTHUR and MUIR, of the West London Hospital are the authors, is not only interesting in itself, but also important as marking a further stage in the co-ordination and systematization of radiology. Hitherto we have had descriptions of the methods employed by individual workers; now we have an effort to gather up certain accepted and reliable conclusions from the great mass of experience accumulated during the past few years. This is not to say that the book before us is a complete portrayal of present-day x-ray practice, for in a truly representative volume the therapeutical side would not be limited to one short last chapter out of ten, even though it may be true that in this branch of the subject uncertainty still prevails, and that the value of the treatment in many cases is still unconfirmed. It is inevitable that a large portion of the *Manual* should be devoted to the choice and working of apparatus, because it is here more than anywhere else that the inexperienced are perplexed by divided counsels. The book has been written—if for one class of workers more than another—for army and navy surgeons; and in dealing with apparatus, the convenience of those who require electrical equipment on the field or apart from the ordinary source of supply is consulted. The working of accumulators is treated most fully, and sometimes, as when dealing with the condenser and the phenomenon of self-induction, the authors take liberty with technical correctness in order to ensure ease of comprehension. With regard to the interpretation of radiograms, there will be general sympathy with Dr. Arthur and his colleague when they insist that only men of sound medical training and experience should be allowed to control the x-ray tube and interpret its results. For the non-professional operator to offer medical opinion upon a radiogram is sheer impertinence, and in dealing with radiographic appearances (of bones and joints, for example) the authors wisely make no attempt to indicate or correlate the pathology of many of the conditions considered. That can, of course, be done for himself by the medical man. They adopt a conservative attitude towards instantaneous radiography, and evidently care little for the somewhat sensational methods of making short exposures which are being advocated. Nor do they believe that orthodiagraphy will soon be superseded, judging by the exhaustive chapter on that subject, in connexion with which they describe a modified arrangement of their own for giving the orthodiasepic outline of the heart and the mediastinal contents—a method which appears to have the merit of simplicity if not of absolute accuracy. The excellent section on diagnosis is illustrated by a series of radiograms and, what are better still, by drawings made from radiograms. These sketches illustrating various conditions of the parts are more successful than some of the diagrams illustrating apparatus; the first of the latter, for instance, gives a rather misleading idea of the earliest x-ray tubes. The substitution of drawings made from radiograms for the unsatisfactory reproduction of the radiograms themselves is a hint for future writers on the subject of the x rays. The authors, however, ventured to reproduce one unique radiogram, secured with the aid of a soft tube, showing distinct shadows of the radial and ulnar arteries, made opaque by an excessive calcification of their walls. The unusual appearance certainly to some extent survives the half-tone reproduction. The work as a whole, in spite of the constant developments of a new science, will probably occupy a standard place in British literature for a long time to come.

The extraordinary literary fertility of German radiologists is illustrated again in the massive compilation by

Dr. WETTERER, of Mannheim, whose manual of Roentgen-therapy² is by far the largest work yet issued on a subject which in England has scarcely attained the dignity of a literature. The water-colour drawings by Fraulein Schneider, reproduced by the four-colour printing method, and illustrating the action of tubes and the appearances of irradiated parts, help to give it distinction, and a bibliography containing more than 2,000 references is another valuable feature. Many readers will turn first to the large section devoted to radiumtherapy, in which the differences between the radium and the Roentgen rays as therapeutic agents, together with the indications for the use of the former, are fully canvassed. The author has found that ten-minute contact applications of radium weekly are of value in certain cases of lupus. The hypertrophic and verrucous varieties react better to radium treatment than the flat, disseminated disease, which is more amenable to the Finsen light. He describes his method of securing an elective action of the rays by inserting aluminium filters between the capsule and the skin, thereby obtaining deeper effects with less violent surface reactions. In dealing with the biochemical effects of the radium rays, he relates the particulars of some experiments upon rats. Sixty milligrams of highly-active radium bromide, applied for two hours, gave rise to a widespread process of degeneration in the reproductive organs of the animals. The sections on Roentgenotherapy cover an immense field, and the statement of the biological side of the question alone would form a substantial treatise. The influence of the x rays upon inflammatory processes in the joints is fully treated, and the author cites cases of arthritis deformans within his own practice, in which disappearance of pain and reduction of swelling were brought about by their use. No chapter is more important than that dealing with x-ray injuries. These are divided into two classes—that is, primary injuries resulting from absolute or relative over-exposure, and secondary or subsequent injuries due to the cumulative effect of radiations upon the same part. The x rays ought under no circumstances to be applied without the most careful use of a dosimeter. Here, he says, punctiliousness becomes a virtue. Absolute over-exposure only takes place, as a rule, if the dosimeter is not used or is used wrongly—as, for example, if the measuring field be in the region of weak and the irradiated field in the region of intense emissions. By relative over-exposure he means the application of normal doses to extra-sensitive tissue. Upon new patches of psoriasis, for instance, a dose of 5 to 6 H. may cause a stubborn dermatitis or x-ray ulcer. As author of a work which indicates wider fields for a new therapy, Dr. Wetterer may, perhaps, be accused of forming the over-estimates of enthusiasm, but his work taps so many sources and invokes so many authorities as to disarm criticism, if not to dispel all doubt. The book is more than a manual; it is an excellently arranged encyclopedia.

The second edition of Dr. PAUL VAUDET'S *Technique Précise de Radiothérapie et Radioscopie*³ fully bears out the intention expressed in its title. It is an exposition of exactness in the application of the x rays to medicine, and the point wherein it differs from other textbooks of radio-therapeutics is in the emphasis it places upon scientific as against experimental methods. The first edition was published in 1905, and the new volume, which is about half as large again as its predecessor, includes a further section on radiography and radioscopy (screen examination), methods of diagnosis which during the past three years have taken a more important place. The main portion, relating to radiotherapy, might have been brought even more fully up to date, for the Roentgen Society of London has been working very much along the lines indicated by Dr. Vaudet, and some of the conclusions published in its journal respecting the standardization of radio-activity and x-ray dosage might have been of service to him. Indeed, one is rather impressed by the absence of the names of British

¹ *Handbuch der Röntgentherapie, nebst Anhang die Radiumtherapie* Von Dr. Josef Wetterer. Leipzig: Otto Neumann, 1906. (Royal 8vo, pp. 910; 198 figures in the text, and 15 plates. M 27.)

² *A Manual of Practical X-Ray Work*. By David Arthur, M.D., D.P.H., and John Muir, B.Sc., M.B., Ch.B., and B.Sc. (Pub. Health). London: E. & S. B. Sonnet Limited, 1906. (Demy 8vo, pp. 256, 126 illustrations. 7s. 6d.)

³ *Technique Précise de Radiothérapie et de Radioscopie. (Instrumentation pratique)*. By Dr. P. Vaudet; with a preface by Professo E. Gaucher. Second edition. Paris: Alfred Delcroix, 1906. (Med. 8vo pp. 223, with 20 plates and 25 illustrations in text. Fr. 6.)

workers, both in the chapters themselves and in the ample bibliography which is appended, although, of course, it must be recognized that the pioneers of precise methods in Roentgen work have been Holzknecht, Sabouraud, Kienbock, and Ondin, who belong to the Continent. Dr. Vaudet dates the end of the empiric period and the beginning of the scientific from 1901-2. It was about this time that Holzknecht brought forward his chromo-radiometer, and stated a definite measurement—namely, 5 H. units—as the quantity of x rays that would produce a definite reaction of the skin. Dr. Vaudet elaborates Holzknecht's discoveries, and deals in an interesting way with the conditions necessary to secure equality of irradiation, the laws governing the intensity of x ray action upon the tissues, the degrees of reaction, periods of latency, and methods of localizing the rays and protecting doctor and patient. He looks forward to the day when it will be possible to prescribe a dose of x rays with the same exactness and certainty as a chemical medicament. The newer part of the book introduces a chapter on the working of the screen stereoscope of M. Estanave of Paris. The chapters dealing with the x -ray diagnosis of fractures are valuable, especially in view of the fact that certain conditions, such as incomplete fracture of the acetabulum, are only recognizable by means of the x rays. The detailed information on the radioscopic examination of the pathological thorax will also be of assistance to those who have difficulty in interpreting the shadows. The book may be heartily commended as affording a glimpse of the refinements practised by French workers.

THE CAUSE OF CANCER.

*The Lectures on the Pathology of Cancer*⁴ which Dr. C. P. WHITE has published were delivered in Manchester in connexion with the Pilkington Cancer Research Fund. The purpose of the author has been to give a general outline of the subject and to call attention to certain points which he considers are neglected or imperfectly dealt with by most writers. The book is divided into four parts, dealing respectively with the classification of tumours, the characteristics of cancer, conditions affecting the origin and development of cancer, and advice as to treatment. As Dr. White holds a particularly high reputation for accurate work and sound criticism in cancer research, we are disappointed to find that in this volume he often contents himself with vague generalities where precise explanations would have been more acceptable. An example may be quoted from page 41, where he is comparing cancer cells with unicellular organisms.

Whether or not cancer cells show a still closer resemblance to unicellular organisms by occasionally manifesting a sexual process in the course of reproduction is not certainly known, but various observations on the characters of the mitoses in cancers tend to show that such is the case, although some of the changes seem open to doubt.

Evidently Dr. White is not altogether satisfied with certain recent cytological work, and he may have good reasons; but in scientific criticism vague expressions of opinion, such as that quoted, are unsatisfactory. We want definite statements of the work to which the author refers, definite opinions about it, and scientific reasons for these opinions. Much of what Dr. White says about studying cancer in relation to general biological problems is interesting, but there is too great a tendency to lapse into abstract speculation. Liberal use is made—for example, on pp. 45-48—of metaphorical language about stable and unstable equilibrium.

The immediate essential causal factor of tumour formation is thus an *unstable condition of equilibrium* between the component parts of the body.

Without raising any objection to the use of the term "equilibrium," one would like to know how far its meaning can be expressed in precise language. What are the scientific methods for demonstrating and investigating physiological or pathological "equilibrium" of the tissues? Obviously, in tumour formation, normal intercellular influences are disturbed; but if the conception of "unstable equilibrium" is to be helpful, and not merely a restatement of this obvious fact, it must be shown that the forces which are supposed to be disturbed in their

"balance" lend themselves to examination by qualitative and quantitative methods. Dr. White complains that scientists take too strict a view of cellular pathology, and are accustomed to explain all pathological changes by cellular activities, without considering the organism of which the cells are the constituent parts.

A living organism, however, is not a mere aggregation of cells; it is a distinct entity in itself—an individual—and the cellular activities are everywhere subordinated to the control of the whole organism; . . . the organism does not grow because the cells proliferate, but the cells proliferate because the organism grows.

How does Dr. White propose to study the organism as "a distinct entity in itself"? His point of view seems more appropriate for the field of metaphysical speculation than for experimental science. And his criticism that pathologists limit their attention to "mere aggregations of cells" and neglect "the organism" seems to overlook the enormous amount of valuable work which has been done on immunity and kindred subjects. In fact, the most striking feature of experimental pathology at the present day is the prominence which is given to changes which modify the organism as a whole, or, to put it from Dr. White's point of view, which cause the "organism" to modify its own component parts.

Notwithstanding its ambitious title, we doubt if the pamphlet on the genesis of carcinoma, by Professors APOLANT and EHRLICH,⁵ tells us much which is new or important about the origin of this disease. Professor Apolant, who contributes the histological portion of the article, calls attention to the rarity with which tumour formation occurs in rabbits and guinea-pigs, as compared with rats and mice; he also observes that for each species of animal there is generally one particular organ which is more likely to be the site of tumour formation than the rest of the tissues. In his histological investigations of mouse tumours he finds no corroboration of Ribbert's theory that inflammatory processes in the connective tissue play an important part in the genesis of cancer. According to Professor Apolant,

the development of mouse carcinoma, its further differentiation, its definite outcome, and also the formation of sarcoma, are to be regarded as the product of two factors; the one of these is to be found in the biological properties of the tumour cell, the other in the resistance manifested by the organism in relation to this influence. The working of these two factors, in co-ordination or in opposition, determines all the appearances which have been described.

Professor Ehrlich, attacking the same problem from the biological standpoint, elaborates the theory that the influence of defective nutrition (Athrepsie) plays an important part in tumour formation. This view is based on the results of numerous experiments showing that after a preliminary inoculation with a rapidly-growing tumour the growth of a second piece of malignant tissue inoculated into the same mouse is inhibited. His assumption is that the first and vigorously-growing tumour exhausts the requisite nutritive material, and that in consequence the subsequent inoculum is so poorly nourished that growth is either completely inhibited or greatly retarded. It is to be hoped that Professor Ehrlich will be able to elaborate from this line of research some results possessing a practical therapeutic value.

Dr. AICHEL claims that his hypothesis as to the cause and nature of malignant tumours⁶ is new. For the precise grounds on which he ascribes novelty to his theory we must refer our readers to the text; we find them a little difficult to understand, and we confess that his suggestions seem to us to be closely akin to a cancer hypothesis which is very ancient indeed. Malignant growths, according to Dr. Aichel, can only arise when the somatic cells have absorbed from without a "something" which transforms them into malignant cells. He therefore sets himself the task of ascertaining what this "something" is. After considering various other possible agents and rejecting them in turn, he arrived at the conclusion that the "something" consists of leucocytes. "The normal somatic cell through fusion (Amphimixis)

⁴ *Lectures on the Pathology of Cancer*. By Charles Powell White, M.A., M.D., F.R.C.S. Manchester: University Press, 1908. (Sup. roy. 8vo, pp. 84, with 35 illustrations. 6s. 6d.)

⁵ *Ueber die Genese des Carcinoms*. Von H. Apolant und P. Ehrlich. Jena: Gustav Fischer, 1908. (Sup. roy. 8vo, pp. 94. M. 1.)

⁶ *Eine neue Hypothese über Ursachen und Wesen bösartiger Geschwülste*. Von Dr. Otto Aichel. München: J. F. Lehmann, 1908. (Sup. roy. 8vo, pp. 36. M. 1.50.)

with a leucocyte produces the malignant cell, and from this, through cellular division, a malignant tumour arises." We are not convinced that Dr. Aichel, in the development of this theme, has made any substantial advance on other well-known suggestions that the malignant cell arises from hybrid fertilization by a leucocyte.

GLANDERS.

In this book, *Glanders: A Clinical Treatise*,¹ MR. WILLIAM HUNTING has condensed a great deal of the practical experience of a lifetime. He has kept pace with the discoveries of *Bacillus mallei* and mallein; he has seen the identity of glanders and farcy (the cutaneous form) settled beyond dispute; he has had a large share in influencing and shaping the new regulations for the control of glanders, and now, as chief veterinary inspector of the London County Council, he has a leading share in carrying into actual practice the provisions of the Glanders Order for 1907, so largely inspired by him. The book, then, is the outcome of unique opportunities, and from the clinical and hygienic point of view it is extremely valuable. It does not attempt a complete account of the pathology and bacteriology of glanders, but for the veterinary clinician and for the horse owner it is full of valuable advice the outcome of acute and discriminating observation. The use of mallein is described in detail, and the author points out how, under the old Order of 1894, it was possible for owners to detect disease before it was evidenced by any symptoms; they could then sell the latently-infected horse, and so spread glanders to distant parts of the country. Table IV, illustrating the distribution of glanders, shows that 90 per cent. of the total cases occur in London and the home counties. "I was rash enough a few years ago," the author writes, "to express the opinion that a horse was not infective until clinical symptoms were developed. That was a grave error. . . ." After this renunciation, the author mentions conditions in apparently healthy horses affected with latent glanders which may be dangerous, especially those in which the trachea is ulcerated—a not uncommon lesion. With regard to the method of infection, the author is emphatically in favour of the view that it takes place usually by ingestion; he almost denies the possibility of infection by inhalation, and somewhat unnecessarily attacks the theory of aerial infection in tuberculosis. Speaking of prevention, there are some statements of great interest to private horse owners—namely the dangers (1) of sending horses to livery stables when the owner goes out of town; (2) of turning horses out to grass in the company of other strange horses; (3) of horses being stabled with strange horses at army manoeuvres; and (4) of buying old cast horses from London stables without previous testing with mallein. There is a valuable appendix dealing with cases of glanders in man, and a number of such cases are briefly described. Some of the literature on the subject is mentioned, although in this respect more detail would have been an advantage. The author draws attention to the fact that glanders has been scheduled as an industrial disease, so that employers are liable for compensation; also that by the Glanders Order of 1907 veterinary inspectors have to notify the medical officer of health of cases of glanders. One of the most valuable features of a valuable book is the series of fourteen beautifully executed coloured plates, showing typical lesions of glanders in horses.

THE CRIMINAL: PROPHYLAXIS AND TREATMENT.

In comparatively small compass the author of this valuable little book, *The Principles of Anthropology and Sociology in their Relations to Criminal Procedure*,² discusses on the one hand the development and conclusions of criminal anthropology and criminal sociology, and, on the other hand, criminal law and procedure. The first three chapters are devoted to a succinct account of the principles of the classical school of criminology and the rise of the modern science of positive criminology, as embodied

principally in the teachings of Lombroso, Garofalo, and Ferri; to criminal sociology and to the relation of the criminal to society and the question of penal responsibility. In the two succeeding chapters punishment and the bearing of modern views of the nature of criminality upon criminal law are ably expounded. Thereafter follow descriptions and analyses of the fundamental principles of Anglo-American and Continental criminal law and procedure. After that, in each succeeding chapter, one part of criminal procedure is taken and examined in the light of modern criminological science, suggestions as to alterations and reforms being made at the end of each chapter. The accounts of criminal anthropology and sociology are less happy than those in which comparative criminal law and procedure are treated, the author being somewhat too ready to accept the Lombrosian stigmata as of proved distinctive value. Beyond this, however, we have nothing to utter but praise. The descriptions of comparative criminal procedure are clear and instructive, and the author's criticisms and suggested alterations well worthy of consideration. Perhaps we can best convey the essence of his view of the whole matter by saying that, in his opinion, the sole logical basis of all legal action against the criminal should be the fact and degree of his dangerousness to society, and should not be based on moral or ethical grounds, on the principle of moral liberty or free will. If only this great principle of danger to society be accepted as criterion, most of the reforms in criminal law and procedure—such as the substitution of detention and reform for punishment, the fitting of the degree of repression to the criminality of the delinquent and not to the crime itself, and many other reforms as to prosecution, defence, and simplification of the law must inevitably follow. We hope this book will be widely read.

Another recently-issued book dealing with the same matter, though more restricted in scope and largely statistical in treatment, is a monograph, entitled *Britain's Blot*,³ by DR. J. F. SUTHERLAND, Deputy Commissioner in Lunacy for Scotland. Dr. Sutherland has had twenty-eight years' experience of lunacy, inebriety, and delinquency in Scotland, and is thus well qualified to speak with authority. He is convinced that there are two distinct types of recidivist—namely, the habitual petty delinquent and the habitual criminal, between whom there is nothing in common save their haunts. Further, in each class there is a proportion—in the petty delinquents a large and in the habitual criminals a small proportion—of psycho-pathological cases. An important conclusion arrived at by the author is that there is no established connexion between drink and professional criminality, or, if there be any link, that it is slender and remote. As already stated, a large part of this book is statistical, the figures and maps given relating to the relative incidence of the several crimes and their topographical distribution in Great Britain; but admirable summaries are given also of modern views on criminal anthropology, illustrated by anthropometrical data collected in Scotland, and of the penal systems which obtain in America and on the Continent. Following this, the author discusses prophylaxis, jurisprudence, and penology, and then states his own suggestions for juridical and penal reform. With regard to criminal responsibility, we note that under the heading of "The Criminal Law in Relation to Free Will, Responsibility, and Punishment," Dr. Sutherland says, "a safe and sociological maxim is that the idea of wrong depends upon the moral, intellectual, and physical damage which volition and action bring to society;" and later on, "it might well be that the main purpose of punishment should be the protection of society and of property by the reclamation by improved methods of habitual criminals and offenders who are salvageable, and by the sequestration of those not so under safeguards." In this Dr. Sutherland appears to share the views of the writer reviewed immediately above, but we do not gather that he, like some other modern criminologists, would exclude the question of responsibility altogether, for in discussing the free-will question he avows himself neither a free-willer nor a determinist, but expounds a

² *The Principles of Anthropology and Sociology in their Relations to Criminal Procedure*. By Maurice Parmelee, M.A. The Chilton's Library of Economics, Politics, and Sociology. New York and London: Macmillan, 1908. (Cr. 8vo, pp. 418. 5s.)

³ *Britain's Blot: Recidivism, Criminality, and Habitual Petty Delinquency: A Problem in Sociology, Psycho-Pathology, and Criminology*. By J. F. Sutherland, M.D. Edin. F.R.S.E., F.S.S. Edinburgh: William Green and Sons, 1908. (Med. 8vo, pp. 126. 3s.)

compromising "relativity" which appears to be midway between these two positions, enjoying the advantages of neither. Notwithstanding the passages quoted above, therefore, we doubt whether Dr. Sutherland would follow the bold lead of some who would exclude the moral liberty question altogether, and say that the question in every case is not, Is this man responsible or irresponsible? but Is this man dangerous to society, and, if so, how dangerous? Dr. Sutherland's book contains a great deal of valuable information in small compass.

In the year 1904 a book by Professor ERNST SCHULTZE of Bonn,¹⁰ published that year, entitled, *The Psychoses of Military Prisoners*, formed the subject of an article in the BRITISH MEDICAL JOURNAL of May 28th, 1904, on *Dementia Præcox and Simulation*. In that book Professor Schultze showed how considerable were the numbers of insane military prisoners who had been repeatedly punished for various offences—notably desertion—which subsequent events left no doubt were directly traceable to early but undetected mental disorder. To prevent such occurrences Professor Schultze made several important suggestions, including a compulsory two years' training in mental diseases for all army medical men, a period of mental observation for all persistently refractory soldiers, the employment of mental experts in all doubtful cases, and a regular and systematic inquiry into the mental history and character of all recruits and candidates for the army. Since the date of his earlier work Professor Schultze has had the opportunity of investigating the mental state of fifty-one more military prisoners, before his removal to Greifswald put an end to his opportunity of observing such cases, and the results of his investigations were published in 1907.¹¹ To a considerable extent Professor Schultze's task as reformer has been lightened, for many of the suggestions he made have been put into effect: for instance, recruits now bear with them to the army on joining an account of their school life. Professor Schultze devotes the first five chapters of his new volume to the clinical histories arranged under the categories of manic-depressive insanity, feeble-mindedness, hysteria, epilepsy, and dementia præcox. Lengthy clinical notes, however, are omitted, as sufficient for the purpose were published in the first book. Feeble-mindedness is treated at considerable length, as this forms one of the most important considerations in the question of treating military prisoners. In the next chapter are discussed some cases which do not fall within any of the above categories, and in the last chapter, which takes up more than half the book, Professor Schultze considers the total clinical material with particular reference to the sources of failure to diagnose the condition, the recognition of simulation, the connexion between the mental disorder and the acts for which the individuals were punished, and finally makes further suggestions as to reform. Without entering into details, we may mention that the first work gave an account of the histories, offences, and mental status of 32 insane or mentally defective military prisoners, and the second book of 51 more; making, with 17 cases sent from the Andernach Asylum, 100 cases in all. A large proportion were of either illegitimate or uncertain birth; about one-half were more or less given to alcoholic abuse, and 64, or about two-thirds, had been previously punished, that is, before the commission of the military offence. Naturally, repeated offences were most common in the imbecile class, and in some of these were of great frequency; for example, one had been punished 35 times, another 26 times, and another 16 times. Hysteria and epilepsy came next in frequency, then manic-depressive insanity, and dementia præcox last. Although the histories of cases described in the first work have been continued and brought up to date, so far as possible, in the present book, the matter has been so treated that a knowledge of the former is not presumed. Nevertheless, we should strongly advise those interested in the subject to procure both works. The books will be found to be of the greatest interest and value to criminologists generally.

SQUIRE'S "COMPANION."

SQUIRE'S *Companion to the British Pharmacopœia* is so well known to prescribers of any therapeutic enterprise that it might seem to be sufficient merely to announce the fact that an eighteenth edition has appeared; but this edition has undergone so much revision and expansion that it becomes a duty to give some account of the new volume. Over half a century ago the late Mr. Peter Squire published a comparison of the London, Edinburgh, and Dublin pharmacopœias, and this was succeeded in 1864 by the first edition of the *Companion*, which contained 220 pages. The new edition¹² contains 1,460 pages—610 more than were contained in the seventeenth edition, published nine years ago. The book, in accordance with its title, follows generally the arrangement of the *British Pharmacopœia*, but the official preparations are given under the main heading; thus, under "Hydrargyrum" we find the official plasters, liniment, pill, and ointments, and this is followed by notes upon non-official preparations. After the official title of each drug are given the synonyms, and, in the case of all important drugs, the French, German, Italian, and Spanish equivalents, when they are known. The later headings in each article are solubility, medicinal properties, dose, prescribing notes, incompatibles, official preparations, preparations which are not official, antidotes, foreign pharmacopœias, descriptive notes and tests.

From the first appearance of the *Companion* the subject of solubility has received particular notice, and in the present edition closer attention and a very much larger number of figures have been included. It was suggested in the BRITISH MEDICAL JOURNAL that in those instances in which a substance is extremely soluble in a menstruum the increase in volume caused by its solution should be given. In the more commonly prescribed chemicals this suggestion has been followed in the present edition—thus, ammonium bromide, 1 in 1½ of water measures 2; ammonium phosphate, 1 in 2 of water measures 2½; potassium iodide, 4 in 3 of water measures 4; and quinine hydrochloride, 2 in 1½ of water measures 3. The prescribing notes have been considerably enlarged, and we are informed, and can well believe, that they have involved a very large number of practical experiments. We agree that it is in the best interests both of medicine and pharmacy to give such a note, which is of more value than to suggest a fixed formula, as it leaves the physician a judicious liberty in varying the quantities of the active ingredients in accordance with the requirements of the individual patient. The notes on preparations contained in foreign pharmacopœias will also be useful as an aid to prescribers, beyond their more immediate purpose of indicating, in the case of patients residing abroad, the character and strength of preparations useful in various countries. The notes on medicinal properties, which have been read and revised by Dr. Taylor Grant, are brief, and, as a rule at any rate, very much to the point. The descriptive notes have been read by Mr. E. Morrell Holmes. The paragraphs on tests have been rewritten, and particular attention has been given to the methods for the detection of likely and unlikely impurities.

The doses mentioned are those in which the substance is usually given, but in the cases of potent chemicals, drugs, or preparations, the doses are compared with the maximum single and daily doses of one or other of the more important foreign pharmacopœias, or where such information is not available, with a textbook of recognized foreign standing such as Hager. The tabulated comparison of the chief standardized potent preparations of the British, United States, German, and French pharmacopœias will be found useful for reference. A chapter on thermometric memoranda and special tests has been included. The article, on therapeutic agents of microbial origin, has been revised and partly rewritten by Dr. R. Tanner Hewlett. The concluding portions of the book are occupied by lists of the spas of Europe, enumerating first those of Britain, afterwards the Continental, giving the locality, temperature, season and medicinal properties; a list of spas classified according to their temperature and properties is also given. There are three indices—a therapeutical classification of remedies, a list of remedies for special ailments, and a general index.

We often hear complaints that the art of prescribing is

¹² *Squire's Companion to the British Pharmacopœia.* Eighteenth edition. London: J. and A. Churchill, 1908.

being lost, and that the younger generation is tempted more and more to rely upon the ready-made mixtures, pills, and tablets which enterprising wholesale firms present to notice. A book such as this should afford the best remedy, for it gives in a convenient and reliable form just such information as the prescriber needs when he desires to step a little outside his own beaten track.

DERMATOLOGY.

THE new and enlarged edition of the justly popular manual, *Diseases of the Skin*,¹³ by Sir MALCOLM MORRIS, has been brought up to date by him, with the assistance of Dr. ERNEST DORE. The large amount of work done in the dermatological world since the third edition was published (in 1903) has necessitated increasing the book by forty-eight pages, but at the same time the object of the author to write a manual and not a treatise has been well kept in view, with the result that a very handy volume has been produced. A feature of the work is that the index, which by the way is very full, enables the reader to see at a glance the main lines of treatment available in any given disease. A careful perusal of this well-known manual proves that the authors have done their work of revision thoroughly. They have been discriminate in their selection of material, and there is no doubt the book fully deserves the favour it has met with in the past. The plates are excellent and add to the value of the book.

A book, *Die Praxis der Hautkrankheiten*, embodying and founded on the dermatological teaching of Dr. Unna, has been recently brought out by Dr. IWAN BLOCH.¹⁴ It is a large, closely-printed volume, that will repay perusal on a variety of points which have been investigated in an original and special way by Dr. Unna: and it may be said at once that the author has very thoroughly assimilated the master's teachings, but he has unfortunately produced an unyielding and indigestible morsel, made up of a minced-up mass of details. Notwithstanding this drawback, the work is one that will be used for reference with profit by all specially interested in diseases of the skin; the more so as a good index is provided. The introductory chapters on the anatomo-physiological aspects of the subject and the histological and staining technique are of special importance, for dermatology is much indebted to Dr. Unna for the staining methods he has introduced and perfected. In the sections on pathology and treatment again valuable information is given.

The *Treatise on Diseases of the Skin*,¹⁵ by Professor STELWAGON, of Philadelphia, which has been several times dealt with in these pages, continues to enjoy such popularity that a fifth edition has been called for. In this instance the high praise already bestowed upon this excellent work can merely be repeated. But it should be added that the present issue has been thoroughly revised. The book is in every way excellent—text, illustrations, and form, making it one of the foremost works of reference on a subject of great complexity.

Earlier editions of Dr. NORMAN WALKER'S *Introduction to Dermatology*¹⁶ have been reviewed in these columns, and the popularity of the book can be gauged from the fact that a fourth edition has been called for. With every edition there is distinct improvement. The coloured illustrations are very good, and show a great advance in artistic merit on those of previous editions. This is due to the excellent casts of Dr. Cranston Low. In his preface the author states his belief—one shared by many teachers—that students are none the worse for being taught dogmatically. It must not be forgotten, however, that dogmatic teaching

if pushed too far, may interfere with the free play of the power of observation. Some of the greatest clinical teachers have followed what may be called the Socratic method, which, while it does not eliminate judicious dogmatism, at the same time stimulates the power of reasoning from observation. As an introduction to dermatology, Dr. Walker's book can be highly recommended. The diagrams showing the microscopical characters of the various morbid conditions are most valuable, for a knowledge of these lesions is of the utmost importance in diagnosis and treatment.

THE SENSES OF INSECTS.

THE name of Forel is so well known as that of an accomplished observer of what used to be called, and what might still very well be called, the habits of insects, that the reader will take up the volume entitled *The Senses of Insects*¹⁷ with the expectation of being at once instructed, interested, and even amused. Nor will he be disappointed, for the book teems with striking original observations, with acute reasoning and with scathing criticism. But if the reader hopes to find in it a reasonably brief and consecutive statement of Forel's own conclusions, he will be deceived. The book consists of a series of papers written at different times, and later on collected into a budget, which took a long time to get published; additional notes, comments, and criticisms being added here and there. Mr. MACLEOD YEARSLEY, to whom the work of translation has clearly been a labour of love, has, as he explains in his preface, done something to put the several sections into logical order, but he has not felt justified in omitting or paraphrasing Forel's polemics, which render the book a study in the psychology of man as well as insects.

Having said so much by way of doing our duty, and warning the reader of the kind of book he is asked to buy, we may go on to commend it most heartily to every one who has a love for natural history. The old-fashioned term is used advisedly, for it is by no means necessary to be a specialist in order to enjoy nearly every page. There is so much that is curious, so much that is stimulating to thought, so much indeed, if we are in a mood to be metaphysical, that goes to the very root problems of existence.

After nine chapters on vision, smell and taste, and hearing, we find two on orientation in space which to many readers will prove the most interesting part of the volume. Forel rejects utterly, and with vehemence, the theories of a special mysterious force, or of a static or geotropic sense. Orientation, or the so-called homing sense, he says, the result of experience gained through known senses, especially sight and smell. In aerial flight it is the sense of sight which is most important, and, in the bee as in the pigeon, is probably the only sense concerned.

Mr. Yearsley has added some explanatory footnotes, the longest containing a triumphant criticism of the assertions of Cyon and others with regard to Japanese dancing mice. The assertion is that this animal possesses only a single semicircular canal. Mr. Yearsley quotes Dr. Gray of Glasgow, who has dissected the ear, and can find no difference between the canals of the waiting and those of the ordinary mice. The point is illustrated by the reproduction of a very beautiful preparation by Dr. Gray in which the three canals are very plainly visible.

NOTES ON BOOKS.

THE thirty-fifth volume of *St. Thomas's Hospital Reports* for 1908 is edited by Dr. H. G. TURNER and Mr. W. H. BATTLE.¹⁸ Besides the ordinary medical, surgical, and gynaecological reports by the respective registrars, and those of the various special departments by members of the honorary staff, there is a report for 1906 from the Clinical and Pathological Laboratories by Dr. Leonard Dudgeon and one from the X-ray Department by Dr. Greg. The volume also contains four original papers—

¹³ *Diseases of the Skin: An Outline of the Principles and Practice of Dermatology*. By Sir Malcolm Morris, K.C.V.O., etc., with the assistance of Ernest Dore, M.D., etc. London: Cassell and Co. 1908. (Crown 8vo, pp. 702, 10 coloured and 47 black and white plates, with illustrations in text. 10s. 6d.)

¹⁴ *Die Praxis der Hautkrankheiten* [The Practice of Skin Diseases]. Unna's Lehrbuch. Von Dr. Ivan Bloch. Berlin und Wien: Urban und Schwarzenberg. 1908. (Sup. roy. 8vo, pp. 712: 92 illustrations. M.18.)

¹⁵ *Treatise on Diseases of the Skin, for the Use of Advanced Students and Practitioners*. By Henry W. Stelwagon, M.D., Ph.D. Fifth edition. Philadelphia and London: W. B. Saunders Company. 1907. (Royal 8vo, pp. 1150, 257 illustrations and 34 full-page coloured and half-tone plates. 25s.)

¹⁶ *An Introduction to Dermatology*. By Norman Walker, M.D., F.R.C.P. Fourth Edition. Edinburgh and London: W. Green and Sons. 1908. (Demy 8vo, pp. 350; with 28 coloured plates and 69 illustrations. 9s. 6d.)

¹⁷ *The Senses of Insects*. By A. Forel. Translated by Macleod Yearsley, F.R.C.S. London: Methuen and Co. (Med. 8vo, pp. 340. 10s. 6d.)

¹⁸ *St. Thomas's Hospital Reports*. New Series. Edited by Dr. H. G. Turner and Mr. W. H. Battle. Vol. XXXV. London: J. and A. Churchill. 1908. (Demy 8vo, pp. 512. 8s. 6d.)

one on the reduction *en masse* of strangulated and non-strangulated herniae, by Mr. A. B. Howitt and Mr. Edred Corner, who also contribute one on the treatment of gangrene in strangulated herniae; a third on the etiology of the granular kidney of childhood, by Dr. J. E. H. Sawyer, in which he suggests a similar causation as for the more rapidly progressing cirrhosis of the liver; and a fourth on the bacteriology of the more unusual forms of conjunctivitis, by Mr. P. N. Pantou.

The third volume of the eighteenth series of *International Clinics* for 1908¹⁹ contains an unusually large number of papers—twenty-five in all. Among them is one by Dr. J. Jastrow, entitled, On the Trail of the Sub-conscious, and another on Chronic Milk Infection (Marasmus), by Dr. R. B. Gilbert. But that which for its subject-matter is especially valuable is one by Mr. James Sherren on the diagnosis of injuries of the peripheral nerves from those of the spinal cord, in which he applies the conjoint observations of himself and Dr. Head to practical surgery.

The twentieth volume of the *Transactions of the Southern Surgical and Gynaecological Association* covers the work done at the annual meeting held in New Orleans in December, 1907. It has been edited by Dr. W. D. Haggard, and is notable for the excellent reproduction of engravings and other pictures of an early date, dealing with subjects connected with anatomy, surgery, and gynaecology, with which the address delivered by the President, Dr. Howard A. Kelly, of Baltimore, on art applied to medicine and surgery, is illustrated. Apart from this interesting paper, there are some fifty others dealing with various points in surgery. The majority deal with general surgery rather than the special field of gynaecologists. Included is an excellent and prolonged discussion on the treatment of fractures.

In the autumn of 1907 the dermatologists gathered in force in New York, and as an outcome we have received two portly volumes entitled the *Transactions of the Sixth International Dermatological Congress*, 1907.²⁰ Each of these volumes contains some 500 pages, and both are adorned by numerous plates. The book doubtless constitutes a mine of information with regard to current opinions on dermatological subjects; but though there are lists of specimens exhibited and of cases shown, and of contributors, and something in the way of a general index, there is no general list of papers read. It is to be feared, therefore, that much of the excellent work done at this congress will be utilized by a far smaller number of persons than might otherwise be the case.

¹⁹ *International Clinics*. A Quarterly. Edited by W. T. Longcope, M.D. Eighteenth series, 1908. Philadelphia and London: J. B. Lippincott Co. 1908. (Roy. 8vo, pp. 365.)

²⁰ *Transactions of the Sixth International Dermatological Congress*. Edited by Dr. J. A. Fordyce, Secretary-General. New York: The Knickerbocker Press, 1908.

MEDICINAL AND DIETETIC PREPARATIONS.

ORGANIC ARSENIC COMPOUNDS.

"*Kharasin*" and "*Orsudan*."—Two new organic compounds of arsenium have been recently introduced by Messrs. Burroughs, Wellcome, and Co. (Snow Hill, London, E.C.), under the names "*Kharasin*" and "*Orsudan*." *Kharasin* is described as sodium 3-methyl-4-aminophenyl-arsenate, containing 23.7 per cent. of the element arsenium, and *Orsudan* as its acetyl derivative, containing 25.4 per cent. of arsenium. Both are white crystalline powders, very readily soluble in water; they are also supplied in the form of 1-grain tabloids, for administration by hypodermic injection or by the mouth. Specimens of these which we examined dissolved completely with great readiness.

Arsacetin.—We have received from Messrs. Meister, Lucius, and Brüning, Limited (51, St. Mary Axe, London, E.C.), a specimen of a new organic arsenium compound which they have recently introduced under the name "*Arsacetin*." This is described as sodium para-acetyl-amino-phenylarsinate, or acetyl-atoxyl, and it is stated that the introduction of the acetyl group results in producing a compound of much lower toxicity (just as acetalanilide is less toxic than aniline, or phenacetin than phenetidine), and of greater stability and similar therapeutic effect. *Arsacetin* is a crystalline white powder, readily soluble in water; examination showed it to be free from inorganic arsenious and arsenic compounds, while rich in arsenium.

Preparations of Atoxyl.—Messrs. R. W. Greiff and Co. (20, Eastcheap, London, E.C.) have forwarded samples of various preparations for the administration of atoxyl (sodium para-amino-phenylarsinate). These include tablets containing 0.05 gram ($\frac{3}{4}$ grain) of atoxyl with sugar of milk; tablets containing the same amount together with $\frac{3}{4}$ grain of lactate of iron; capsules containing 5 grains of Bland's pill mass with $\frac{3}{4}$ grain of atoxyl; and ampoules of solution of atoxyl for hypodermic injection. Examination of the specimens showed that the tablets disintegrated well in water; the capsules contained the iron in the ferrous condition, but the envelope did not dissolve at all readily when shaken in warm water.

Hydrogen Peroxide.

Messrs. McKesson and Robbins (New York; London agent, Mr. A. C. Wootton, 14, Trinity Square, E.C.) supply a stable solution of hydrogen peroxide for medical and surgical purposes, under the name "Pyrozone." This is a 3 per cent. solution, and it is claimed that it will keep for at least six months without loss of strength. We have recently examined a specimen which had been in our keeping for over seven months, and found it to contain just 3.0 per cent. of real peroxide, with only 0.05 per cent. of mineral acid.

Compound Liquorice Powder without Sugar.

Messrs. Lorimer and Co. (Britannia Row, Islington, N.) have submitted a sample of their Pulv. Glycyrrh. Co. sine Saccharo, in which sugar is omitted and the powder sweetened with saccharin. The dose is thereby reduced to one-half, and the powder is made more suitable for use by diabetic or gouty patients.

MEDICAL AND SURGICAL APPLIANCES.

The Single-Service Milk Container.

A MONO-SERVICE MILK-PAIL which seemed to offer several advantages in the distribution of milk and its care after reaching the household was noticed in this column on June 15th, 1907. We have recently received from America a pamphlet dealing with the "Single-service Container," and describing a paper vessel which seems to be identical with the mono-service milk-pail with the exception of an alteration in the lid. Along with the pamphlet is enclosed a report on the appliance from Dr. A. H. Stewart of the Bacteriological Laboratory of the Bureau of Health, Philadelphia. This report is entirely favourable, and Dr. Stewart states that the milk contained in the single-service container is cleaner bacteriologically and will keep two days longer sweet than that in the ordinary glass bottle. Amongst other advantages of the container over the glass bottle, he enumerates the low initial cost and the absence of loss from breakage, the saving of labour and money in the re-collection and cleansing, lessened weight, and the impossibility of contamination in transit. With these opinions we see no reason to differ. As the containers can be supplied at a cost of 1d. for 20 quart or 25 pint vessels there should be an ultimate saving in their use over that of glass bottles. We should be pleased to see one of the large dairy companies giving the apparatus a trial.

A Help for Very Bad Sight.

One of the most useful appliances which we have recently seen for the assistance of those unfortunate cases which have but little vision left in the only seeing eye is a spectacle suggested and used for some years in suitable cases by Mr. R. W. Doxey, of London and Oxford. It consists simply of an aplanatic lens of about 14 or 15 D. set in a spectacle frame, and having fixed in front of it a bar which is adjusted so that when it is touching the paper which the patient is about to read things are at the best focus, while it also indicates to the patient the line which he is reading. Every one knows how a patient with perhaps advanced optic atrophy is enabled just to read with a large convex lens which greatly magnifies the print. The great disadvantage of this is that the lens must be held in one hand and moved backwards and forwards, so that it is never steady, nor is it kept at the right focus. This disadvantage is completely done away with in the instrument under notice, while the patient very soon gets to be able to run his eye along the line with ease and precision. Its limits must be recognized. It is utterly unsuitable and useless for any one with binocular vision, or who can in any way use the two eyes; it should only be ordered for patients who have but one eye effective, the sight of which is so bad that only by strong magnification of the print is reading possible. The instrument is made by Messrs. Davidson and Co., Opticians, Great Portland Street, W.

ROYAL COMMISSION ON VIVISECTION.

FOURTH REPORT.

(Continued from page 288.)

WE continue our abstracts from the evidence of which the minutes are contained in the fourth report of the Royal Commission on Vivisection, issued in December, 1907.*

Evidence of Professor Lorrain Smith.

Dr. Lorrain Smith gave evidence on behalf of the University of Manchester and the Pathological Society of Great Britain and Ireland. After describing the experimental work carried on at the university, he said the work of the public health laboratories was highly valued by a large number of local authorities, representing about five millions of people, and officers of public health found their reports of great value as regarded the detection and prevention of the spread of disease. Some of the hospitals also availed themselves of these reports, which were often very helpful in diagnosis. The university had never had reason to find fault with any of the licensees for the manner in which the experiments had been carried out. It considered further restrictive measures unnecessary and undesirable. The experiments necessary in the Public Health Laboratory were practically all inoculations. Over 2,000 animals a year were used for investigations for sanitary authorities. The cases of diagnosis of diphtheria in which it was found necessary to resort to other than cultural or microscopic investigation was a very small proportion. In his own department experiments were made for purposes of investigation chiefly. He had conducted a good deal of research at Belfast; this included researches into conjunctivitis. It was not inoculation in the sense of taking a definite bacillus or streptococcus of a known virulence; it was rather an accidental inoculation which might arise from merely wounding the surface. So far as he could observe there was no great pain in these experiments. The eyeball did not slough; there was only a little conjunctivitis. The aim of the experiments was to avoid severe effects on the part. The animal was kept, he thought, a month or two afterwards. Then the eyes were examined microscopically after death to see if one could discover any trace of inflammation or any degeneration, or even the presence of microbes. But they discovered nothing by that method. The witness then described the aim and methods of pathological investigation. He dwelt on the fact that the point arrived in the investigation of disease when progress was practically stayed unless one had recourse to experimental methods. Arterio-sclerosis was a disease of the walls of arteries of insidious origin, commencing usually at about middle life and gradually progressing until it became directly or indirectly a cause of death. It led to hæmorrhage and softening of the brain, to various forms of heart disease, and to a slowly developing form of Bright's disease. The various forms of the disease had been carefully described, but its cause was not known, and to gain this information they required to have in their possession some agent which would set up the process. Josué made the discovery in 1903 that repeated injections of adrenalin into the circulation of rabbits set up a form of arterio-sclerosis in the walls of the vessels. Adrenalin promised to be of still greater value, since it might enable them to discover the cause of arterio-sclerosis. Then pneumonia was one of the most common of acute diseases, and might be studied in two ways: (1) The bacteria which caused it, and (2) the conditions of the patient which rendered him liable to become infected. The second only concerned him at that time. People carried about in their mouths and elsewhere the bacteria which caused pneumonia. Hence, the question before the pathologist was not merely to explain where the infection came from, but the conditions of the patient which permitted the pneumococcus to spread from its usual haunt in the mouth and throat and find its way to the lungs, where it set up inflammation. In order to work out these conditions one point to which to direct

attention was the lungs themselves. Could an agent be found which in itself might be used to cause pneumonia without the aid of bacteria? Such an agent had recently been discovered by the experimental method. It had been found that to submit an animal to an atmosphere of oxygen would, ere long, bring on pneumonia. The simplest possible way, therefore, of working out these conditions, so far as the lung itself was concerned, was to place the animal in an atmosphere richer in oxygen than the air they normally breathed. Pneumonia had been very fully studied by the methods of morbid anatomy, and the data obtained were of great value in enabling them, to understand the cause of the disease, but they had yet much to learn regarding the activity of the lung and its relation to the onset of inflammation. It was at this stage of the problem that experimental investigation became necessary in order to test the truth of hypotheses suggested by the data obtained. A third illustration he had taken from a study of derangements in metabolism. The commonest and most important of these was fatty degeneration. Such a change was seen, for example, in cases of poisoning by arsenic, but that disturbance might be due to a large variety of causes. It occurred more or less universally in gland cells, and its importance might be gathered from the fact that in the muscular fibres of the heart wall it formed one of the most serious types of heart disease. In regard to this condition a great amount of information had been obtained by means of starvation experiments. It was thought that fat appeared in the cells, say, of the liver in such conditions from dilapidation of the cell substances; but by means of these experiments evidence had been obtained that the presence of fat was in many cases to be explained by the absorption by these cells of fat transported by the blood from the tissues under the skin and elsewhere which normally contained fat. The starvation experiments consisted in depriving the animal of food. The animals were dogs and birds. In order to study the kind of fat found in the process of degeneration, the animal was deprived of food until its body contained little or no fat. They were supplied with water. They were deprived of food for a week or two, or even for a month. At the end of that time the animals were fed up again. They showed no symptoms of pain. They were unhappy; there were no particular symptoms. In fact, there was an experiment on record where the milk of a bitch was studied after a period of starvation in this way. It had had puppies, and was able to suckle them. After the animals were starved of fat they were fed with fat of other animals which was of a different character. Then one could follow the relation of this abnormal fat to other tissue changes. A great deal of light had thus been thrown on the process of fatty degeneration. Another important branch of this investigation was exemplified by nervous disease. It had been for years a well-established fact that one of the earliest changes in nervous disease was a breaking down of the nervous tissue system into fat, which was absorbed by lymphatics and disappeared. These changes were found in the dead body in damaged nerves in the spinal cord and brain, and the investigation of them had been carried out by the methods of morbid anatomy with great energy and success. Since it had been discovered that changes of this nature were found in the spinal cord associated with the occurrence of local inflammation elsewhere, as, for example, the presence of pus in the pleural cavity, this form of tissue disintegration had been taken up experimentally, and it had been shown that slow absorption of the poisons generated by bacteria took place along the nerve sheath, and that these poisons on reaching the spinal cord set up fatty changes in the tissue of the spinal cord at the point where the nerve branched off. In other words, they had obtained a new means of attacking the obscure problem of the causation of such diseases as general paralysis, locomotor ataxia, and recurrent insanity. Asked if he had been successful with animals in stopping cases which he believed he saw, he said it was rather early to say that, because the research was just in process. He considered there was very reasonable prospect of success. Finally, he wished to refer to a disease regarding the causation of which they had as yet no knowledge—rheumatoid arthritis and osteo-arthritis. What in that case was required above all things was the means of experimental

investigation of the disease. Something very similar to the disease was found in animals. So far they had not been able to reproduce it. Asked by Colonel Lockwood if he had any objection to the present restrictions placed by law upon operations on living animals, the witness said, No. He did not know that it had placed Englishmen at a very serious disadvantage as compared with other nations. In reply to further questions, he said he thought he would be expressing the feeling of pathologists that further restrictions would delay research, and so far they would object to them. He had seen a fair number of experiments upon living animals, and had never seen any cruelty connected with them. In all the cutting experiments he had witnessed the animals had always been under anaesthetics. He had witnessed none of the starvation experiments to which he had referred. They were not carried on in England. Asked by Sir William Collins what had been learnt by experiments on animals in addition to Gull's and Sutton's work, Dr. Lorrain Smith said they had learnt that they had got a substance that would cause arterio-sclerosis. They were working out the effect of this substance. It was quite a new investigation. He had not witnessed the experiments in connexion with it. In reply to further questions, he said the submission of the animal to an excess of oxygen caused pneumonia, apart from any organism. That was an example of inflammation without bacteria. In man the usual pneumonia was caused by bacteria. Asked if the result of his investigations was to suggest that oxygen ought not to be employed in the treatment of pneumonia, he said he had debated that point with physicians like to the late Dr. Dreschfeld. It was rather difficult to answer it definitely. He thought Dr. Dreschfeld did not use it when he saw these experiments. He agreed that if oxygen produced pneumonia, the use of oxygen in pneumonia would be rather a homoeopathic remedy. Proceeding, he said he did not wish to disparage the importance of morbid anatomy as a means of research. He merely wished to indicate that the natural development of the study of disease was to commence with morbid anatomy, and that the experimental work was required to test the conclusions. Asked if he accepted the *Bacillus paratyphicus* as the cause of paralysis, he said the experiments he had seen were done by a variety of toxin-producing microbes; the *Bacillus coli* was tried and Gaertner's bacillus, and he thought, a mixture of bacilli. The result of those investigations was that one got definitely degenerative lesions in the spinal cord at the point where the nerve emerged. Asked if the evidence pointed to spinal paralysis being a bacillary disease, he said that in this particular part probably it did not; but there had been a large amount of evidence published lately to connect it with the diphtheroid bacillus. This investigation was rather to show that experiments had found out a mode of introducing the toxin into the nervous system in a form in which it had local effects. Apparently, so far as he had seen the experiments, the toxin might be of various kinds. Asked if he had been able to produce the results that he identified with those of general paralysis without the use of the *Bacillus paratyphicus*, he said, Yes, they had, with ordinary bacilli such as were found in the intestines, been able to produce effects of this order. He had tried the same experiment with poisons derived from other than bacillary sources. In reply to further questions, he said the fasting experiments on dogs were performed by Rosenfeld and Lebedeff. Rosenfeld published them in the *Zeitschrift für klinische Medizin*. As far as he knew no similar investigations had been made in this country. In reply to Sir John McFadyen, he said it would be in his opinion entirely unnecessary, as a means of ensuring compliance with the Act, to legislate so as to give greater publicity to the names of those engaged in vivisection, and to give in fuller details for public information the nature of the experiments. He had no reason to suppose that painful experimentation was carried on in this country. The statements about the cruelty and pain which were inflicted were misrepresentations, so far as he knew. He thought that that misrepresentation of the facts might be an honest misrepresentation, but that it might be continued, and even increased, if the laity were provided with details even of painless experiments. Asked by Sir Mackenzie Chalmers if, when he experimented under Certificate B, he understood that not only the cutting operation

itself, but any subsequent painful part of the operation, such as stimulating a nerve, or sewing up the wound, must be done under anaesthetics, he said, Yes. In reply to further questions, he said he represented the council of the university, which was the executive body. Mr. John W. Graham, who had given evidence, and described himself as Principal of Dalton Hall in the University of Manchester, did not represent any faculty of the university. Mr. Graham was not a member of the council of the university. Dalton Hall was a hall of residence for students. So far as he knew, no inquiry was made by Mr. Graham as to what went on locally in his own university. Asked whether general paralysis of the insane was not commonly supposed to be a sequel of syphilis, he said, Yes. His work had not necessarily tended to negative that in any way. Their work had been rather on the method in which toxins were absorbed so as to localize the lesions in the spinal cord. Various toxins might produce the same degenerative effects. In reply to Mr. Ram, he said he thought the treatment of fatty degeneration of the heart, or medical knowledge with regard to it, had been advanced by the starvation experiments on animals. The witness was then asked by Dr. Gaskell to tell the Commission about the case of Mr. Cecil Shaw which had been referred to by the Hon. Stephen Coleridge. Was it true that Mr. Shaw did experiment without a licence? Dr. Lorrain Smith said, No. The witness did the experiment. An eminent ophthalmologist in Belfast, now deceased, appealed to him to undertake this research. The witness was not specially acquainted with ophthalmology, therefore he associated himself with an ophthalmologist, and it was in these circumstances that the combination came about. Mr. Cecil Shaw practically did the whole research except the vivisection part of it. Asked why his name did not appear in connexion with it, he said it should have done; it would have been less ambiguous. These experiments which he had just recounted with regard to the absorption of toxins along the nerve sheaths was in the line of this investigation; it had engaged his attention more or less continually ever since. He had explained the whole circumstance and the Irish Home Office was satisfied with his explanation. He was attacked another time about doing experiments without a licence himself in a research on bacteria of the intestines of dogs, although he stated in the investigation that the intestine was removed after the animal was dead. He did not consider that the experiments on the eye caused the rabbits a good deal of pain. They did not succeed in causing iritis. It was a very minute quantity of jiquirity, the least speck of dust on the point of a camel-hair brush. No inflammation was caused except conjunctivitis. In reply to further questions, he said that at Manchester he did not demonstrate to students. There were no demonstrations in pathological experiments and experiments involving vivisection. He considered that such experiments might be useful to students. He knew how he was impressed the first time he saw a physiological experiment. One of the things that stood out in his recollection of Professor Rutherford's teaching almost more clearly than anything else was the experiment of blood pressure. He could not say what anaesthetics he used. He had no specific recollection of the point, but he was sure the animal was anaesthetized throughout. Sir William Church said they had had a witness before them lately who seemed to be under the impression that when an animal was kept under chloroform by means of having a tube introduced into the trachea, and then vapour of chloroform supplied to the animal through that tube, the tube was introduced without the use of anaesthetics—in other words, that the wound was made without the use of anaesthetics. The witness said he had never seen it done. He agreed that there was no difficulty whatever in keeping an animal under anaesthesia under those circumstances.

(To be continued.)

AN International Congress on Leprosy is to be held at Bergen in August next. We understand that Sir Jonathan Hutchinson and many prominent dermatologists will take part in the proceedings, and that the etiology of the disease will occupy a large place in the discussions.

RADIUM:

ITS PHYSICAL AND CHEMICAL PROPERTIES.

RADIUM and the kindred radio-active bodies furnish an excellent example of the logic of discovery. In a sense it may be argued that the x rays—and thus eventually radium—were found by a happy accident, being the outcome of a series of experiments on the electric conductivity of gases at low pressures; but the x rays and the phenomena connected with them merely gave an indication of the experiments which led up to the discovery of radium, the most revolutionary discovery of modern science.

THE DISCOVERY OF RADIUM.

It is common knowledge that during a discharge of electricity at high tension, through an attenuated gas, material particles (cathode rays) having a mass equal to the thousandth part of the mass of an atom of hydrogen are driven at enormous velocity from the cathode, and that when these material particles are stopped in their career, they produce fluorescence and give rise to the x rays, believed to be either light waves of exceedingly short wave lengths or an irregular series of pulses set up in the ether. The fact that these rays produce fluorescence when they impinge on barium platino-cyanide and similar substances suggested the search which eventually culminated in the discovery of radium. Becquerel investigated various fluorescent bodies to see whether they gave rise to the x rays, and found that in the case of the fluorescent uranium salts a penetrating radiation could be detected. Further research showed that all salts of uranium—whether previously exposed to the light or not, and whether fluorescent or not—were able to give off rays affecting a photographic plate. A search was made for similar substances and it was soon found that thorium appeared to possess a similar property. The fact that uranium, when pure, was less active than certain native minerals containing it prompted further investigations, and eventually three new substances were discovered, all of which showed radio-activity, polonium, radium, and actinium, radium being enormously the most active of the various bodies.

PHYSICAL PROPERTIES OF RADIUM.

There is no need to detail the methods of preparation of radium from pitchblende. Enormous quantities of pitchblende have to be worked in order to procure a few grams of the mixed chlorides of radium and barium, and advantage is taken of the relative insolubility of radium chloride to effect separation by fractional crystallization. To prepare a gram of the chloride 10,000 kilograms of the mineral must be treated.

When once radium chloride had been obtained pure, except for minute traces of barium, the first question presenting itself was whether radium was or was not an element. This was solved by Demarcay by spectroscopic methods. The atomic weight of radium has since been determined, though not with certainty, as about 225. For the purposes of research, the most important property of radium is the power it possesses of making gases conductors of electricity. This property renders it possible to standardize samples of radium-bearing substances, to determine the relative activity of radium under different conditions, and, in a word, to study it in a quantitative manner. Standardization is effected by noting the speed with which a given electroscope is discharged owing to the ionization of the surrounding air.

In the address delivered by Sir Frederick Treves at the London Hospital, published after revision by him at p. 317, he described the three types of radiation produced—the alpha, beta, and gamma rays—and also the remarkable gas or emanation that is given out by radium. Among other properties the self-luminosity of radium salts was described. It may be noted that the greater the purity of the salt the less the luminosity, for the bulk of the fluorescence is due to the bombardment of barium impurities by the rays emitted from the radium. In connexion with this self-luminosity the curious fact may further be noted that it decreases with the lapse of time, but that it may be recovered by recrystallizing from a solution in water.

Another remarkable physical effect produced by the presence of radium is the power which the rays have of increasing the electric conductivity of liquids and solids as well as gases. The thermal effects of radium are too well known to require any description.

THE EMANATIONS.

Owing to the nature of the case Sir Frederick Treves was unable to discuss any details of the very peculiar properties connected with the so-called emanations or gases given off by radio-active bodies. It is noticeable that all attempts to get an emanation from polonium or uranium have so far resulted in failure. The radium emanation is obtained by dissolving a radium salt in water and bubbling air through the solution. Relatively large quantities are thus continuously produced for a short time, but soon the radium is completely deprived of its emanation and the radio-activity of the preparation vanishes for the time. About a month is required before the radium has fully recovered its original activity.

The properties of the emanation are even more remarkable than those of the parent body, radium. It is radio-active, but it loses its activity in an exceedingly short space of time. Within three and three-quarter days the activity has been diminished by half, and the fact has been determined that in the same time the radium from which the emanation was produced, and which temporarily lost its activity, has regained as much activity as the emanation has lost. In other words, the sum of the activities of radium and of the emanation of radium is constant. This statement remains true whatever length of time is considered.

The phenomenon has been explained by Rutherford and Soddy by their "disintegration theory." These observers believe that the atom of radium decomposes as it emits the alpha rays, and that radium emanation is radium minus the alpha rays or alpha particles. The emanations seem to be chemically inert. By applying Graham's law of the diffusion of gases, their molecular weight appears to be about 100, the atom of hydrogen being taken as unity. The radium emanation has a boiling point of about -150°C ., and the thorium emanation of about -120°C . Sir Frederick Treves has explained how the emanation deposits a substance on the walls of the vessel in which it is contained. If the activity of the deposit is considered, it is found that it decreases in a peculiar manner in three definite stages. The first stage is short, and during this the activity, as measured by the alpha rays, falls with great rapidity. The second stage is marked by a constant discharge of activity showing no signs of decay, while in the third stage the rate of decay is very much slower than in the first. It is believed that the emanation decomposes into three radio-active bodies, known as Radium A, Radium B, and Radium C, these being transformed into one another in alphabetical order. When this change has occurred, however, and when Radium C may be imagined to have decomposed, radio-activity persists. This can be shown to be of a complex character, and it has been necessary to assume the existence of still further bodies called Radium D, E, F, and G. This conclusion is based on the way in which the production of alpha, beta, and gamma rays is found to wax and wane. For example, when one of these bodies is being examined it will be found that the alpha rays are continually increasing in amount, while there may be few, if any, beta or gamma rays. After a short period the alpha rays will be found to have disappeared and the beta and gamma to preponderate, and at a later stage the types of radiation produced may be reversed, and so forth.

ORIGIN OF RADIUM.

It was stated above that uranium gave rise to no emanation. It has been found, however, that it does give rise to a body more radio-active than itself, Uranium X. When this is separated from uranium, the activity of the uranium is found to be diminished, just as the activity of radium is lessened by the removal of its emanations. The importance of this will be seen later.

In view of the fact that radium is continually being subjected to a process of decay, it is clear that it must be continually produced. It is always found closely associated with uranium. The suggestion has been made that actinium

provides the necessary link between uranium and radium. The following experiment was therefore conducted. A solution of actinium chloride, prepared from a quantity of carnotite ore containing 20 per cent. of uranium, was sealed up in a glass bulb and tested intermittently for traces of radium emanation. Two months after the experiment was started, the amount of radium emanation recovered corresponded to 5.7×10^{-9} grains of radium. The bulb was again sealed, and after 193 days emanation corresponding to 14.2×10^{-9} grains was found. In other words, 8.5×10^{-9} grains had been produced in 193 days. In this solution about 200 grams of uranium was present. It has since then been shown by Rutherford that radium is not produced directly from actinium, but from ionium, which is usually associated with actinium. The application of this discovery to geology by Professor Jolly last year at the meeting of the British Association in Dublin was probably the most original contribution made on that occasion.

The following table illustrates the putative kinship of radium:

Substance.	Time to Fall to Half Value.	Nature of Rays.
Uranium	4,500 years	Alpha.
Uranium X	22 days	Beta and gamma.
Ionium	—	—
Radium	1,500 years	Alpha.
Radium emanation	3.75 days	Alpha.
Radium A	3 minutes	Alpha.
Radium B	26 minutes	Slow beta.
Radium C	19 minutes	Alpha, beta, and gamma.
Radium D	40 years	Gamma rays.
Radium E ₁	6 days	No rays.
Radium E ₂	4.8 days	Beta rays.
Radium F (Polonium) (Radio-tellurium)	143 days	Alpha rays.

Now radium F, or polonium, is radio-active, and must certainly change into some other substance. It may be noted that with uranium the following elements usually occur: Lead, thorium, bismuth, and barium, and also the gases hydrogen, argon, and helium. Now the last of these substances is generally regarded as identical with the alpha particle emitted by radium. Ramsay has shown that radium emanation can be got free from helium, and that as it decays within a sealed tube helium makes its appearance. If, however, emanation is allowed to decay in contact with copper sulphate, argon is produced instead of helium, while in the presence of water neon makes its appearance. No mention need be made here, in view of the prominence that has been given them, of the apparent transmutation of copper under the influence of radium emanation to lithium, and possibly sodium, by Sir W. Ramsay. It should be noted, however, that Madame Curie has tried to repeat Ramsay's experiments, using platinum vessels without success.

The hypothesis has long been suggested that lead is the final product of radio-active change. It is noticed that in primary ores of the same geological age the ratio of uranium to lead is constant. In the case of thorium, barium, and bismuth no such relation holds. The most serious objection to this theory is that, while the atomic weights of uranium and lead are 240 and 207, fourteen transformations would have to occur within this very short range. Another difficulty consists in the fact that the atomic weight of radium emanation seems to be about 100.

Many problems are raised by the most elementary study of radio-activity. From a gram of a radium salt a stream of energy is continually flowing; nothing affects this constant discharge. It is immaterial whether the salt is wet or dry, whether it is heated almost to the glowing point or whether it is plunged into the extreme cold of liquid air, it can be made to enter into one form of chemical compound or another, it can be mixed with other salts, and subjected to the action of powerful

electrical or magnetic forces and still the bombardment continues, containing in its minute bulk all the gorgeous radiant majesty of a shower of incandescent meteorites. The hypothesis that radium derives its energy by absorbing energy radiated to it through space breaks down on investigation, and the fact that radium evolves energy from itself is established beyond dispute. The chemical changes which the element undergoes are entirely unaltered by conditions of temperature, and are so enormously greater in amount than any of those with which the chemist is acquainted, that no chemical hypothesis can be advanced.

It is believed, therefore, that the atom of radium is being continually disintegrated, a conception harmonizing remarkably with the hypothesis of atomic structure advanced independently by Sir J. J. Thomson. The theory is a return from a different standpoint to the fundamental ideal set forth by Prout and others since his time as to the unity of all forms of matter. Prout believed that the various elements were all built up of hydrogen, and, in fact, were multiples of that element. Sir J. J. Thomson's hypothesis is that the elements are built up of minute vibrating systems of corpuscles, and these corpuscles are the small bodies known as the beta rays. They, as Sir Frederick Treves pointed out in his lecture, are negatively charged and may be regarded as having inertia of purely electrical origin. The positive alpha rays, on the other hand, have a mass comparable with that of hydrogen, and a difficulty arises from the fact that no similar positive electrified body with only electrical inertia has been demonstrated to exist.

Despite this condition, however, pointing as it does to a difference in kind between negative and positive electricity, Sir J. J. Thomson's view of the atom has much to recommend it. The atom would consist of negatively charged corpuscles rapidly moving in orbits, within a sphere of positive electricity. The corpuscles would arrange themselves in systems and there would be a certain critical value necessary for the atom's stability. From such a system, energy derived from the rotation of the corpuscles would be slowly radiated. The velocity of the corpuscles would be reduced, their stability would be suddenly upset, and during the explosive moment of rearrangement certain portions of the atom would be set free as radiations. A fact strongly in favour of the accuracy of this view is that it was designed to explain the general behaviour of atoms. It is at the least a highly remarkable coincidence that it should be found to fit in closely with the new knowledge derived from the study of so remarkable a substance as radium.

BIBLIOGRAPHY.

The bibliography of radium and radio-active substances is already enormous; probably the best and most recent general account is to be found in the volume entitled *The Radio-active Substances: their Properties and Behaviour*, by Mr. Walter Makower, Assistant Lecturer in Physics in the University of Manchester, reviewed in the *JOURNAL* of October 24th, 1908, p. 1277.¹ The volume on *Radio-activity*, published in 1904 by Professor Soddy,² who has himself contributed much to the investigation of the subject may also be consulted; and his paper on "A method of applying the rays from radium and thorium to the treatment of consumption," published in the *BRITISH MEDICAL JOURNAL* of July 25th, 1903, p. 197, may still be read with interest. Those who wish to follow the development of the subject may consult the files of *Nature* for the last few years. Our Paris correspondent gave an interesting account of the therapeutic use of radium at the St. Louis Hospital in cancer of the skin and mucous membrane in the *JOURNAL* of January 23rd, p. 242.

¹ London: Kegan, Paul, Trench, Trubner, and Co., 1908, 5s.

² London: Electrician Publishing Co., 1904.

THE report presented to the eighth annual meeting of the Peckham Nursing Association stated that the organization, which exists to give nursing attendance free to the poor in their own homes, and to attend cases of sickness and operation among the middle classes for a moderate fee, had received a grant from the Metropolitan Hospital Sunday Fund. Since its foundation over 26,000 visits had been paid to 1,191 poor patients.

CREMATION.

PROGRESS OF CREMATION.

For some years past we have published figures, obtained from official sources, as to the number of cremations carried out in this country and the establishment of new crematories. On each of these occasions we have taken the opportunity of urging upon the medical profession the advantages of this mode of disposing of the bodies of the dead, alike in regard to the respect due to those who pay the inevitable debt of mortality and to the welfare of the living. We have shown that the objection on religious grounds which used to influence the minds of many has lost much of its force. It was met long ago by Lord Shaftesbury's famous question, If the burning of a body interferes with the Resurrection, what becomes of the blessed martyrs? Religious feeling can be satisfied by services when the ashes are placed in the urn just as well as when the body is laid in the grave. The Roman Catholic Church still forbids cremation, but there is reason to believe that this prohibition has a disciplinary and ritual or political rather than a strictly theological basis. In Italy cremation was, when first introduced, regarded, if not intended, as a sign of revolt against clericalism. As the Roman Catholic Church spreads its branches over the world this prohibition, which, if we are rightly informed, in its origin had only a local significance, has been extended over a corresponding area, carrying with it an official disapproval of cremation which has been misinterpreted into a formal condemnation of the practice on theological grounds. It is not surprising, therefore, that in Catholic countries cremation is almost as extraordinary an event as an *auto da fe* would be in these days. It is strange, however, that in what is at present the most anticlerical of countries—France—it makes little progress. In the Jewish community, although cremation is not much practised, there is no official prohibition. In Germany it has lately made rapid headway, notwithstanding opposition on the part of religious bodies. There are crematories at Bremen, Chemnitz, Coburg, Eisenach, Gotha, Hamburg, Heidelberg, Heilbronn, Jena, Karlsruhe, Mayence, Mannheim, Offenbach-on-the-Main, Pörsneck, Stuttgart, and Ulm. The number of cremations carried out in 1908 was, according to *Die Flamme*, 4,050, as against 2,977 in 1907. Quite recently the remains of Prince Edward Saxe-Weimar Eisenach were burnt instead of being deposited in the family mausoleum. This is said to be the first time that the body of a prince of a reigning house in Germany has been cremated. In New South Wales there is a cremation society which held the first general meeting in November, 1908, under the presidency of Dr. Creed, M.L.C., and in Auckland, N.Z., under the presidency of Dr. J. S. Purdy.

In this country, as has been stated in previous articles, many of the clergy are in active sympathy with the movement for the substitution of cremation for burial, and there

are not a few signs that it is becoming more common. It is still, however, almost wholly confined to persons belonging, in an intellectual sense, to the higher classes. This is probably in large measure due to the inertness which makes any departure from long-established custom repugnant to the average, and still more to the ignorant, man. The advocates of cremation should not therefore be discouraged by its slow progress, but should welcome every sign, however trivial, of advance.

It is satisfactory to record that during 1908 there was a decided increase in the number of cremations throughout the country. In this increase the London crematories—Woking, Golders' Green, and Ilford—figure most prominently, the total number being 86, or 20 per cent., more than in the previous year. In the provinces the increase was only 4, or 1.4 per cent. The increase in the frequency of cremation in London is attributable partly to the diffusion of the knowledge of its advantages by the press, partly to the active propaganda carried on by the Cremation Society of England. The table at the foot of this page shows at a glance the progress of cremation in Great Britain during the last twenty-three years.

The following table shows the relative numbers of cremations in London and in the provinces:

London Crematories (Woking, Golders' Green, Ilford).			Provincial Crematories (Manchester, Glasgow, Liverpool, Hull, Darlington, Leicester, Birmingham, Leeds, Bradford, Sheffield).		
1907.	1908.	Increase.	1907.	1908.	Increase.
416	502	86 (20 per cent.)	289	293	4 (1.4 per cent.)

THE SENTIMENTAL ASPECT.

In such a matter as the disposal of the remains of the dead the sentimental aspect cannot be disregarded. Probably what makes the idea of cremation repulsive to many people is the sudden and complete destruction of the tenement in which dwelt the soul of one we knew and perhaps loved. But to any one whose imagination can pierce below the ceremonies and the coffin in which a body is laid to rest, the prevention of corruption by the quick action of fire should surely be more comforting than the thought of any one we knew being doomed in the words of Claudius:

To lie in cold obstruction and to rot.

We have no wish to dwell on the horrors of the charnel house, but we cannot shut our eyes to the fact that burial means decay with its accompanying loathsomeness. To this favour must we all come if we are laid in the earth or, what is far worse, in vaults. The gorge rises at the notion of the process of decomposition. Cremation, on the other hand, has no such disgusting associations.

Table of Cremations Carried out in Great Britain since the Opening of Woking Crematorium in 1885.

	1885.	1886.	1887.	1888.	1889.	1890.	1891.	1892.	1893.	1894.	1895.	1896.	1897.	1898.		Total.

By its means the ashes of the dead may repose inoffensively for an indefinite period amid beautiful surroundings. It justifies the words of Shelley speaking of Keats's grave: "It almost makes one in love with death to think that one would be buried in so sweet a place." The consequences of burial, however, are the reverse of sweet, whereas cremation is an act of kindness to the living as well as to the dead, and enables us to keep their memory undisturbed by ideas of decay.

THE ECONOMIC ASPECT.

It is tolerably certain that cremation will sooner or later be forced upon us as a compulsory measure owing to the want of space for burial. Already municipalities are confronted with the ever-increasing difficulty of enlarging their cemeteries or finding room for new ones. The cost of this will necessarily increase as ground available for the purpose becomes less easy to find, and therefore more expensive. The dangers to health from overcrowded graveyards need not be dwelt upon, as they are recognized by all. Cremation offers the readiest and the best solution. It is not only cleanly and wholesome, but cheap, a circumstance which has to be taken into account by local authorities as well as by private persons.

CRIME AND CREMATION.

The only serious objection to cremation from the point of view of the public safety is the possibility of its destroying evidence of crime. If the provisions of the Cremation Act are complied with, the chances of the body of a person who has died in circumstances warranting any suspicion of foul play being disposed of by cremation are very remote. Indeed, hiding of the evidences of crime is made far more easy by burial as ordinarily carried out than by cremation. For cremation two medical certificates signed by two registered medical practitioners are required; this alone suffices to show how much more stringent the regulations of the Home Office under the Cremation Act are than those for burial. In proof of this it may be stated that according to the latest returns more than 8,000 bodies were buried in 1907 in England and Wales without any medical certificate at all. In an article published in the *JOURNAL* of February 8th, 1903, p. 339, it was stated that since the Home Office regulations under the Cremation Act came into force—that is to say, from May 1st, 1903, to December 31st, 1907—1,739 cases were submitted for cremation to the medical referee. Of these, 7 were referred to the coroner, who held an inquest in 3, and thought such an inquiry unnecessary in 4. In 31 cases certificates were referred back to the certifying doctors for further information or owing to some irregularity in filling up the form. In 20 a *post-mortem* examination was ordered by the medical referee. In 4 cases the medical referee refused to authorize cremation, and in 6, in which the deceased persons were from abroad, it was found impossible to comply with the statutory regulations. Thus, of the total number of cases submitted to the medical referee, in 68, or nearly 4 per cent., further information was required or the necessary authorization was refused.

During 1908, 489 cases were submitted to the medical referee of the Woking and Golders Green Crematories. Thirty-eight of these were referred back, in 4 cases the application was refused or withdrawn, and in 2 from abroad cremation was refused. The reasons of the refusal are to be found in the following rules and orders under the Cremation Act with regard to persons dying abroad or at sea:

The duties of the medical referee shall be as follows:

He shall not (except where an inquest has been held and a certificate given by a coroner in Form E) allow any cremation to take place unless he is satisfied that the death of the deceased has been duly registered by the production of a "certificate of registry of death" on one of the forms provided by the Registrar-General for production in case of burial.

In these cases the registrar never issues a certificate of registry of death, and the coroner very rarely holds an inquest. Therefore, since the medical referee cannot obtain either of these he cannot sanction cremation. For the same reason, a "provisional certificate of registration of death" is of no use for the purpose. The medical referee can only allow cremation on the production of the certificate of registry of death itself. Of the 38 cases referred back by the medical referee during 1908, 4 were reported to the coroner, who held an inquest in each case.

In 27 cases certificates were returned on account of some irregularity in filling up the forms or because further information relative to the cause of death was required. Of these 23 were ultimately passed, and 4 were refused or withdrawn. In 7 cases *post-mortem* examinations were made. These figures, besides showing the care with which permission to dispose of bodies by cremation are issued, suggest that there is considerable laxity as to orders for burial. If the total number of deaths occurring yearly in London is put roughly at 70,000 (15 per 1,000 on 4,700,000 people) and if the figures yielded by the investigation of the number of deaths which come before the medical referee are of any value, it would appear that in London alone in 560 cases of death where burial is now carried out on a registrar's certificate an inquest should have been held, and in 980 a *post-mortem* examination should have been held to establish satisfactorily the cause of death.

Another point which seems to us to make strongly in favour of cremation is the fact that it would place in the hands of the Registrar-General much more trustworthy information than he obtains under the existing system. From the figures we have quoted it is obvious that many of the statistics issued are, in a scientific sense, valueless. Figures collected with the precautions against error required for cremation would be far more likely to supply a more solid foundation for conclusions as to the causes of death and as to the prevalence of certain diseases. In illustration of this it may be mentioned that the Medical Referee for the London Cremation Company has not yet come across a case in which the diagnosis on the certificates was completely substantiated by a *post-mortem* examination. This does not, of course, imply that medical diagnosis is generally at fault; it must be remembered that the cases with which he has to deal are, from the very fact that extra precautions are considered necessary, obscure in their nature, even when they are not open to suspicion in other respects.

CRIMINAL PROSECUTIONS UNDER CREMATION ACT.

During 1908 there was one criminal prosecution under the Cremation Act by the Home Office. The case was tried at Edgware Petty Sessions on May 6th, and a report of it was published in the *JOURNAL* of May 23rd, 1908, p. 1263. An undertaker was charged (1) with unlawfully and knowingly burning the body of a stillborn child; (2) with contravening the regulations made by the Secretary of State by causing and procuring the cremation of a stillborn child otherwise than on the written authority of the medical referee acting on behalf of the London Cremation Company. A report of another case, which was tried since the beginning of the present year, may be found at page 315 of the *BRITISH MEDICAL JOURNAL* of January 30th.

HOW TO ENSURE CREMATION.

There can be no doubt that cremations would be more numerous but for the matter that the wishes of dying persons in regard to this fact are not always fulfilled. The reason is generally that no definite instructions as to the disposal of his body are left by the deceased. It may be well, therefore, that it should be generally known how a person can ensure that his body shall be cremated if he wishes. For this purpose the person desiring it should communicate his wishes to his executors and friends. It is not sufficient merely to insert a direction in a will, because the will is rarely looked at until after the funeral. Moreover, any such direction, having no effect in law, would not bind unwilling executors. It is advisable, therefore, to appoint executors who may be relied on to respect the testator's wishes in respect of cremation. As a further precaution, any gift to them might be made conditional on their doing so. A more certain way is to become a member of the Cremation Society of England (324, Regent Street, W.). Membership, in addition, offers the following advantages:

A Life Member is entitled to be cremated at any Crematorium in Great Britain without fee.

The wish of a person to be cremated after death is more likely to be fulfilled if he is a Life Member. For life membership prepay the cremation fee, and thereby relieves the survivors of a portion of the funeral expenses.

The Certificate of Life Membership, given by the Society, clearly indicates the desire for cremation, and relieves executors and others of the responsibility of deciding. The wishes of many persons are often forgotten, or not acted upon, if no

definite instructions are left. A member, beside being kept in touch with the progress of the movement, by means of publications, etc., has the right to vote at all general meetings of the Society, and therefore to influence its policy.

The following are the rules governing life membership:

Rule 5.

The members of the Society shall be persons of either sex who have been approved by the Council, and who

(a) Pay to the Society a subscription of one guinea per annum.

(b) Qualify for life membership under Rule 6.

Rule 6.

Any person who shall make application to the Society in the form provided for that purpose and pay the sum of five guineas shall thereby qualify as a life member of the Society, and shall as such life member be entitled—subject to the legal forms being complied with—to be cremated at death without further fee at any crematorium in Great Britain that is in working order.

The payment of six annual subscriptions of one guinea shall qualify a person for life membership.

No financial liability beyond the payment of the subscription is attached to membership.

BRITISH MEDICAL BENEVOLENT FUND.

At the January meeting of the Committee twenty cases were considered, and grants amounting to £180 made to nineteen of the applicants. Appended is an abstract of the cases relieved:

1. Widow, aged 70, of M.R.C.S. No income; slight help from children. Relieved sixteen times, £173. Voted £10.
2. Daughter, aged 33, of late M.D. Glas. Used to support herself by nursing, but the last three or four years has had very bad health, and is now quite incapacitated. No income; slight help from a friend and the Distressed Gentlefolks' Aid Association. Relieved four times, £41. Voted £10.
3. Daughter, aged 64, of late M.R.C.S. Had maintained herself as a governess from the age of 16 until a few years ago. Invested her savings in a company which has just gone into liquidation. Voted £12.
4. M.R.C.S., aged 65. Used to have a good practice, but has lost several patients through death and removal. Receipts last year not very much more than his rent, and is not in good health. Voted £12.
5. L.R.C.S. Dub., aged 64. Was a ship's surgeon for many years, but was obliged to resign, having contracted a drug habit, and now finds it impossible to get work, although there is every reason to believe that for five years he has taken neither narcotic nor stimulant. Was given an interim grant of £2 at Christmas, and now voted £5, with leave to apply again in six months, a medical friend undertaking to receive the money and satisfy himself as to the use made of it.
6. Widow, aged 85, of M.R.C.S., L.S.A. Only income £25 a year from the United Kingdom Beneficent Association, and has been bedridden for six years. A friend who formerly helped died recently. Voted £5.
7. L.R.C.P. Edin., aged 78. Used to have an excellent practice, but receipts have greatly fallen off owing to changes in the neighbourhood, and applicant has unavoidably exhausted his savings. Voted £12.
8. Daughter, aged 49, of late L.R.C.P. Edin. No means, and is not in a fit state for undertaking remunerative work of any sort. Voted £10.
9. Medical student, who hopes to get qualified in eighteen months' time, but whose father recently died, leaving applicant and four sisters quite unprovided for. A grant has been made him at his school and help is promised by local friends, but meanwhile money is urgently needed for unavoidable expenses. Voted £20, to be distributed to the family at the discretion of an honorary local secretary.
10. Wife, aged 39, of M.D. Edin., who is confined in an asylum. Income £13 a year. Has taken lodgers, but is at present unable to do so on account of a recent surgical operation. Two children, aged 13 and 12. Relieved four times, £28. Voted £10.
11. Widow, aged 59, of M.R.C.S. No income. Slight help from children. Has permanently injured her right hand. Relieved five times, £58. Voted £12.
12. Daughter, aged 71, of late M.R.C.S., L.S.A. Income £20 a year, and carous a few shillings occasionally by needlework. Relieved nine times, £35. Voted £5.
13. Widow, aged 60, of L.R.C.P., L.R.C.S. No income; health failing; endeavours to earn a little by needlework, but finds it difficult to obtain. Relieved ten times, £105. Voted £12.
14. Widow, aged 38, of M.R.C.S., L.S.A. Quite unprovided for at husband's death. No income; slight help from friends; has maintained herself as a housekeeper until about a year ago, when she developed phthisis. No children. Relieved once, £5. Voted £5.
15. Widow, aged 51, of M.R.C.S., L.S.A. Quite unprovided for at husband's death, and with the assistance of this fund and relations has brought up her four children, whom it is hoped will soon be able to support her. Relieved thirteen times, £150. Voted £12.

16. Daughter, aged 68, of L.R.C.P., L.R.C.S. Edin. After father's death at the age of 92 applicant became a teacher, properly intended for her support having had to be realized. Has now a teacher's pension of £15 a year and a little help from the Indigent Gentlewomen's Fund. Relieved twice, £23. Voted £5.

17. Widow, aged 55, of L.F.P.S. Glas. Nursed her husband for several years before his death, and now endeavours to support herself by letting lodgings. No children. Relieved once, £5. Voted £5.

18. Daughter, aged 57, of late M.R.C.S., L.S.A. Maintained herself for several years as a governess, but now dependent on small earnings from needlework and music pupils. Relieved once, £12. Voted £12.

19. Widow, aged 54, of L.R.C.P., L.R.C.S. Ire. No income; children do not help. Relieved four times, £41. Voted £6.

Contributions may be sent to the Honorary Treasurer, Dr. Samuel West, 15, Wimpole Street, W.

Nota et Vetera.

A MEDICAL ROLL OF HONOUR.

PHYSICIANS AND SURGEONS WHO REMAINED IN LONDON DURING THE GREAT PLAGUE.

WHEN the Great Plague of 1665 occurred in London, there was a general stampede of all who could leave the city. The exodus included those to whom the distressed inhabitants naturally turned for help, namely, the clergy and the doctors; and the panic-stricken and plague-stricken inhabitants were left largely in the hands of irregular practitioners in both professions. The medical refugees included men of high reputation and great wealth; among them one, at least, whose name is a household word in the annals of medicine. All the officers of the College of Physicians, led by their president, fled; to find, on their return, that their college had been broken into and the college coffers emptied.

How many medical men remained at their posts is not accurately known. There were not many. Apparently not more than twenty-five. Not a large number to minister to the medical needs of a population estimated at 240,000 and in a time of pestilence. No list has been preserved of this small band of heroes. A study of contemporary literature, however, and an examination of valuable manuscripts in the Guildhall Library, most kindly transcribed by Mr. Edward M. Borrajo, the City Librarian, has enabled the compilation of the following list, which, however, cannot pretend to be more than an approach to completeness:

I. PHYSICIANS.

In the compilation of the following biographical notes, Monk's valuable "Roll of the Royal College of Physicians" has been largely drawn upon:

Allen, Thomas, is mentioned by Pepys as being in London during April, 1666, when the Plague was still raging severely. Dr. Allen was educated at the University of Cambridge (Trinity and Caius Colleges) where he took the degrees of M.B., 1654, and M.D., 1659. He became a member of the Royal College of Physicians in 1659, a Fellow in 1671, and Censor in 1674-79, and 1682. He was a Fellow of the Royal Society and Physician to Bethlehem Hospital. He died of "dropsy" in 1684.

Baber, Sir John, resided in King Street, Covent Garden. He was the son of Mr. John Baber, Recorder of Wells, Somerset, and was born April 18th, 1625. He studied first at Winchester and then at Christ Church, Oxford. After graduating M.B. (1646) at Oxford, he travelled abroad and took his M.D. (1648) at the University of Angers. On returning to London he joined the Royal College of Physicians, becoming a Fellow in 1657 and Censor in 1660. He was appointed Physician-in-Ordinary to Charles II. and knighted by that monarch, March 19th, 1660. He died in 1703. Sir John Baber's presence in London during the plague year is established by entries in *Pepys's Diary*.

Barwick (or Berwick), Peter, resided in St. Paul's Churchyard, until his house was destroyed by the fire of 1666, when he removed to Westminster. He was the son of Mr. George Barwick, of Witherslack, Westmorland, and was born there in 1619. He was educated at Sedbergh Grammar School, and then at the University of Cambridge (St. John's College), where he took the degrees of B.A. (1642), M.A. (1647), and M.D. (1655). He

joined the Royal College of Physicians in 1655, became a Fellow two years later, and was Censor in 1674-84 and 1687. This good man seems to have been noted for his loyalty, his piety, and his charity. He was with Charles I at the battle of Worcester, remained steadfast to the Royal cause during the Commonwealth, and at the restoration was appointed a Physician-in-Ordinary to Charles II. He is mentioned by Dr. Hodges in *Loimologia* as one of those who remained in London during the plague year. During the whole of that year he never missed attending daily service at St. Paul's Cathedral. His practice was to rise at 6, walk over to the Cathedral for prayers, and then return to his house to see gratuitously all sick poor who came to seek his aid. He seems to have stimulated the Cathedral clergy to their duty, for one of the canons writing to the Dean, states that Dr. Barwick had been inquiring as to the celebration of the Holy Communion, which appears to have fallen into abeyance, possibly from the fear of spreading contagion. In old age he became completely blind and suffered severely from stone. He died in his 84th year and was buried in the crypt of St. Faith beneath St. Paul's Cathedral. He married the widow of an eminent merchant, and left a daughter who became the wife of Sir Ralph Dutton, Bart., of Sherborne.

Brooks, Humphrey, lived in Leadenhall Street. He was a Londoner by birth, and was educated at the Merchant Taylors' School. He subsequently went to Oxford (St. John's College), and took there the degrees of B.A. (1640), M.B. (1646), and M.D. (1649). He was admitted a member of the Royal College of Physicians in 1640, and chosen a Fellow in 1674. He was Censor in 1675-80-81-84 and 1692, and "Consiliarius" in 1693. He died "very rich" at the age of 76, and was buried in the Church of St. Andrew Undershaft. He was the author of a work entitled, *A Conservatory of Health, Comprised in a Plain and Practical Discourse upon the Six Particulars Necessary for Man's Life* (London, 1650, 12mo). His presence in London during the plague is vouched for by his contemporary, Dr. Hodges.

Burnett, Alexander, of Fenchurch Street, was M.D. Camb. 1648, and F.R.C.P. Lond. 1648. Dr. Burnett, while engaged in company with Dr. Glover, Dr. O'Dowd and two other physicians in making an autopsy upon a person who had died of the plague became himself infected and died August 25th, 1665. All present at this fatal *post-mortem* examination caught the virus and died, some the same day, the rest the day following. Dr. Burnett was ordinary medical attendant to Pepys, the celebrated diarist. Pepys says the plague was first brought into the city itself (it had begun in the western suburbs) by the doctor's own manservant. Under date August 10th, 1665, he writes: "To my great trouble hear the plague has come into the city, but where should it begin but in my good friend and neighbour's Dr. Burnett in Fenchurch Street, which in both points troubles me greatly." Dr. Burnett seems to have taken the necessary precautions for protecting his neighbours, for under date August 11th Pepys writes: "I saw poor Burnett's door shut, but he hath, I hear, gained great goodwill among his neighbours, for he discovered it himself, and caused himself to be shut up of his own accord, which was very handsome." Referring to Dr. Burnett's death, Pepys has the following entry: "Aug. 25.—This day I am told that Dr. Burnett, my physician, is this morning dead of the plague, which is strange, his man dying so long ago, and his house this month opened again. Now himself gone! Poor unfortunate man!" Pepys was evidently not aware that Burnett had contracted the disease at a *post-mortem* examination and not from his servant.

Congers, William, was born in 1622. He received his early education at the Merchant Taylors' School, and then proceeded to Oxford (St. John's College), where he graduated M.D. in 1653. He was admitted a member of the Royal College of Physicians in 1656, and settled to practice in London. "He was," says Dr. Monk, "one of the few physicians who remained in London during the Great Plague, devoted himself to the duties of his position and the succour of the sufferers from that disease, to which he himself fell a victim."

Coysh, Elisha.—It is doubtful whether this physician should receive a place in this list. He had a house in the City and another at Highgate. When the plague broke out he left the former and retired to the latter, where he

received such patients as could afford to reach him there. Dr. Coysh was M.D. Oxon. (1657), and F.R.C.P. Lond. (1673). He died in 1685.

Glisson, Francis, resided in New Street, St. Bride's, Fleet Street. He was the son of Mr. William Glisson of Rampisham, Dorset, where he was born in 1597. He entered the University of Cambridge (Cains College) in 1617, and graduated B.A. in 1620, M.A. in 1624, and M.D. in 1634. He became a member of the College of Physicians in 1634 and was elected a Fellow in 1635. He was Gualstonian Lecturer in 1655, Censor in 1656, and President in 1667-8-9. In 1636 he was appointed Regius Professor of Physic in the University of Cambridge. In 1648 he was residing in Colchester, and during the siege of that town was one of those selected to make terms with Lord Fairfax. He returned to Cambridge, but his salary as Regius Professor falling much into arrear (he received no stipend for about five years), he came to London and obtained an Order in Council, dated March 7th, 1654, for payment of the sum due to him. He did not return to Cambridge, but remained in London and joined a small body of scientific men which became the nucleus of the Royal Society. He published at least two important works, one in 1650, on Ricketts, the first description of that disease issued in this country; the other, in 1654, on the Liver, in which "Glisson's capsule" is first described. He died October 14th, 1677, and was buried in St. Bride's Church, Fleet Street. His services during the Plague are gratefully referred to by Dr. Hodges in his work *Loimologia*.

Glover, John, was born in America, and studied at the University of Harvard, where he graduated in arts. He then came to this country, and graduated M.D. (1654) at the University of Aberdeen. He settled in London, and became an Honorary Fellow of the Royal College of Physicians in 1664. He was one of those who met his death (August 25th, 1665) at the *post-mortem* examination in which Dr. Burnett and others took part.

Hodges, Nathaniel, resided in Watling Street. This remarkable man was the son of the Vicar of Kensington, and was born at the old Kensington Vicarage, September 13th, 1629. He was educated first at Westminster School. He entered Trinity College, Cambridge, in 1646, but in 1648 he was transferred by the Parliamentary Visitors to Christ Church, Oxford, where he completed his university career, and where he graduated B.A. in 1651, M.A. in 1654, and M.D. in 1659. Settling in London, he was admitted a "Candidate" of the Royal College of Physicians in 1659 and a Fellow in 1672. He was Censor in 1682, and Harveian Orator in 1683. During his Censorship he presented to the College a fire-engine. During the plague, his daily routine, taken from his autobiography, is thus described in the *National Dictionary of Biography*:

He rose early, and took an antipestilential lectuary as large as a nutmeg. After transacting household affairs, he entered his consulting room. Crowds of patients were always waiting, and for three hours he would examine them and prescribe, finding some who were already ill and others who were only afflicted by fear. When he had seen all he breakfasted, and visited patients at their houses. On entering a house he had a disinfectant burnt on a hot coal, and, if hot or out of breath, rested till at his ease, then put a lozenge into his mouth, and proceeded to examine the patient. After spending some hours in this way he returned home, and drank a glass of sack, dining soon after off roast meat and pickles or other relish, condiments of all sorts being cheap and abundant in the city during the epidemic. He drank more wine at dinner. Afterwards he saw more patients at his own house, and paid more visits, returning home between eight and nine o'clock. He spent the evening at home, never smoking tobacco, of which he was a professed enemy, but drinking old sack till he felt thoroughly cheerful. After this he generally slept well. Twice during the epidemic he felt as if the plague had infected him, but after increased draughts of sack he felt well in a few hours, and escaped without serious sickness.

Dr. Hodges's valuable services to his fellow-citizens do not seem to have met with the recognition they deserved. He was constantly harassed by want of money, and was frequently in debt. From the Corporation he received two gifts of £100 each (Guildhall Library MS. 270). Nevertheless, his poverty increased, and it seems incredible that this faithful public servant was allowed to end his days in a debtor's gaol. Yet such was the case. Dr. Hodges died in the Fleet Prison on January 10th, 1688. He was buried in St. Stephen's, Wallbrook, where a handsome monument has been erected to his memory. Dr. Hodges wrote several works on the plague, the most important of which is

Zoimologia, or an Historical Account of the Plague in London in 1665, published in Latin by the author in 1672, and translated into English by Dr. John Quincy in 1720. Readers of Harrison Ainsworth's novels will recollect that it was Dr. Hodges who attended the grocer's daughter in *Old St. Paul's*.

O Doud, Dr. was one of those who, with Drs. Burnett, Glover, and others, met his death in making a *post-mortem* examination on a person who had died of the plague on August 25th, 1665. He received his M.D. degree from the Archbishop of Canterbury. Further particulars of him have not been obtained.

Paget, Nathan, was the son of the Rev. Thomas Paget, Rector of Stockport, but born (1615) in Manchester. He went first to the University of Edinburgh, where he graduated M.A., then studied medicine at Leyden, where he graduated M.D. in 1639; returning to this country, he settled in practice in London. He became an Extra-Licentiate of the Royal College of Physicians in 1640, a "Candidate" in 1643, a Fellow in 1646, Censor in 1655-7-9-67-8, and Harveian Orator in 1664. He died in 1677. He is mentioned by his contemporary, Hodges, as one of the few physicians in London during the plague. He was an intimate friend of Milton, and married a cousin of the poet's third wife, Elizabeth Minshull.

Peck, Samuel.—Particulars of this physician are wanting. He is not mentioned in Munk's "Roll of the College of Physicians," nor in the lists of graduates of any British university. He probably graduated abroad. He is mentioned, however, more than once in the City archives as "Dr. Sannuel Pecke, Dr. in Phisicke," and the following entry shows that he resided in London, and did meritorious work during the plague year: "Bolton, Mayor, 26 February, 1666.—Upon the humble desire of Doctor Peck, who did especial service in visiting and prescribing physic to the poor infected in the late visitation of the plague within this city and liberties, it is ordered by this Court that Mr. Chamberlain shall pay unto him the sum of fifty pounds in recompense of the said service." (From MS. 295 in the Guildhall Library.) Peck had further sums from the Corporation, amounting in all to £100.

Wharton, Thomas, resided in Aldersgate Street. He was descended from an ancient North of England family, and was the only son of Mr. John Wharton of Winstou, co. Durham, where he was born in 1614. He studied at both the Universities of Oxford (Trinity) and Cambridge (Pembroke). He did not, however, at the time receive a degree from either, but subsequently—namely, in 1647—by virtue of letters patent issued by the Parliamentary General, Sir Thomas Fairfax, he received the degree of M.D. from the University of Oxford. Meanwhile he had been up in London studying physic under Dr. Bathurst, Physician to Oliver Cromwell. Having obtained his degree, he was admitted a Member of the Royal College of Physicians in 1648, and a Fellow in 1650, and held the post of Censor for the years 1658-61-6-7-8-73. When the plague broke out he set himself seriously to determine whether he should remain in London or flee. He decided to remain, being induced to that course, it is said, out of consideration for the large number of poor people who attended his clinic at St. Thomas's Hospital, of which he was then Physician. To St. Thomas's Hospital, also, the Government sent all the Foot Guards as soon as they were seized with the plague. For his services to the troops Wharton was promised the first vacant post as Physician-in-ordinary to the King; but when the vacancy arose he was put off with an augmentation in his coat of arms, for which he had to pay Sir William Dugdale, the Herald, £10.¹ Dr. Wharton died in 1673, and was buried in the Church of St. Michael Bassishaw, where a marble tablet bears an eloquent testimonial to his worth and work. Dr. Wharton was the author of *Adenographia* (in which "Wharton's duct" is first described), published in London in 1646, and again in Amsterdam in 1659.

Witherley, Sir Thomas, was a member of the University of Cambridge, and received his M.D. degree there in 1655. He became a Fellow of the College of Physicians in 1677, Censor in 1683, and President in 1684-5-6-7. He was Physician in Ordinary to King Charles II. He died March 25th, 1693. For his services during the plague he received two sums of £100 each from the City Corporation (Guildhall Library, MS. 270).

II.—SURGEONS.

Most of the books of the Barber-Surgeons Company were destroyed in the Great Fire of 1666. The courteous Clerk of the Company, Mr. F. C. Lingard, however, has kindly furnished what particulars he could collect, and these, with certain details from the Guildhall MSS., has enabled the following brief notes to be prepared of Surgeons known to have been in London during the plague:

Effe, John, cannot be traced in the books of the Barber-Surgeons Company, but he is stated to have received from the City Corporation the sum of £40 for his attention to the sick poor (February 22nd, 1666).

Gray, Thomas, having been apprenticed first to Mr. John Hancock and then to Mr. William Hunt, was admitted "Chirurgion" October 12th, 1652. For his services to the Plague patients he received from the City the sum of £30. He seems to have fallen a victim to his duties, for the Corporation granted to his widow a sum of £70.

Hannan, Edward, having been apprenticed to Mathew Alsopp, was admitted a "Chirurgion" December 2nd, 1652. For his services during the Plague the Corporation voted him the sum of £30, and he dying, apparently from the distemper, his widow received in 1666 also a sum of £30.

Higgs, Edward, having been apprenticed to Mr. Dextery (sic) Saunders, was admitted a "Chirurgion" April 14th, 1629. For his services in "dressing the poore visited of the plague," the City Corporation voted him at various times sums amounting in all to £90.

S. D. CLIPPINGDALE, M.D., F.R.C.S.

SOUTHWOLD LIBEL CASE.

UPON the suggestion of local members of the profession, who desire to give practical expression to their sympathy with Drs. Mullock and Tripp, of Southwold, a fund has been opened to assist them in defraying the heavy expenses which they have incurred as the result of the recent action which they were called upon to defend. Cheques to be made payable to Dr. H. P. Helsham, Beccles, or Dr. W. Tyson, Lowestoft, and crossed "Barclay and Co." The following amounts have been already promised:

	£	s.	d.
Dr. C. J. Acton, Wangford	10	10	0
Dr. Bruce Goff, Gloucester Place, W. ...	5	5	0
Dr. H. P. Helsham, Beccles	5	5	0
Dr. H. M. Evans, Lowestoft	5	5	0
Dr. W. Tyson, Lowestoft	5	5	0
Dr. W. A. Sham	3	3	0
Dr. W. Berry, Lowestoft	3	3	0
Dr. W. L. Bell, Lowestoft	3	3	0
Dr. Alex. Macleod, Notting Hill	2	2	0
Dr. A. C. Baileman, London	2	2	0
Dr. H. Blake, Yarmouth	1	1	0
Dr. S. Barradell-Smith, Lowestoft	1	1	0

A Correction.

We regret that the report of the above case which appeared in our last issue (p. 314) was incorrect in the following particulars. We set out the alleged libel as it was printed in the statement of claim; but as a matter of fact the libel actually relied on by the plaintiff was contained in the following letter addressed by Dr. Mullock to Dr. Wilson Tyson:

"Wymering House, Southwold,

"7th May, 1908.

"Dear Sir,—I shall be obliged for your opinion on a point of medical ethics.

"In January, 1907, there were three practitioners in this town—Dr. Herbert, and Tripp, in partnership, and I. Dr. Herbert left the town, and Dr. Tripp took on the practice by himself, buying Dr. Herbert's share. About March Dr. D. T. MacLeod appeared, took the house which Dr. Herbert had lived in, and put his plate up. He called on Dr. Tripp and me after some delay, and told us he had come here for his health, and really didn't want many patients, but that if he was called, and to attend any of our present patients he would at once let us know. He is now attending some of our patients, but in only one instance in my practice has he informed me of the fact. Dr. Tripp has never heard from him on the subject. Many unpleasant things have happened almost from the time of Dr. MacLeod's advent: such as attempting to get the use of a bed for one of his patients at the hospital, not asking our permission (Dr. Tripp and I comprise the medical staff). We once interviewed him on the subject, when he denied that he was in any way to blame. His wife goes to our patients and tells them of her husband's successes, and insinuates that he, having had so much experience, must know more than younger men. We have had suspicions for some time that Dr. MacLeod has been 'touting,' but we have never had any definite proof until the present instance. On the 2nd of this month he approached a patient of mine, who is the caretaker in the local golf club, and the following conversation ensued: 'You are looking very badly?' 'I have one of my headaches,' she replied.

I must give you something for it,' said he, 'but as I cannot examine you here, come to my house to-morrow, and I will see what I can do for you.' She demurred, but he overpersuaded her. She went to his house, and he kept her there for one and a half hours, and examined her eyes, etc.

'I heard a rumour of this on the 4th instant, and went at once to my patient, when she told me exactly what occurred. She said she had no wish to leave me, and was quite satisfied with the way I had always treated her and her family.'

'Dr. D. T. MacLeod had a practice at Dunvegan, Jews' Walk, Sydneyham, some years ago, which he said he left because his health broke down through overwork.'

'Dr. Tripp is quite in sympathy with me, and will combine with me in any concerted action which may be necessary.'

'I have submitted above facts to the Medical Defence Union, who advised me to communicate with you. I have not approached Dr. MacLeod on the subject.'

'What do you advise?'

'Yours truly,

'R. W. MULLOCK.'

MOTOR CARS FOR MEDICAL MEN.

A HAND-CLEANER FOR MOTORISTS.

THE motorist or cyclist who believes in the efficiency of "the master's eye" in promoting the duration and good working of his engine or machine is likely to attend to many minor repairs for himself. One of the greatest disadvantages in doing so is that any handling of the working parts of a motor or cycle usually leaves the hands blackened and greasy. The "Flash" hand-cleaner supplied by Messrs. Brown Brothers, Limited (Great Eastern Street, London, E.C.), is introduced to provide a more efficient cleansing agent for such cases. It is a paste containing a soapy basis with a considerable proportion of ground pumice; the latter greatly facilitates the removal of dirt and grease, and the preparation is most useful for its purpose. It is described as being antiseptic, but does not appear well suited for surgical cleansing, which is, of course, not the purpose for which it is intended.

THE COST OF MOTORING.

DR. R. MARTIN (Medical Officer Banbridge Dispensary District, co. Down) writes: I have read with much interest the article on "Motor Cars for Medical Men" in the JOURNAL of January 2nd, and also Dr. Cropper's remarks and those of Dr. Relfon in the issue of January 16th. In connexion with this I would like to give my experience. In the middle of October, 1907, I purchased a 10-h.p. two cylinder Chamber's car, and up to the present time I have covered 7,500 miles, and my total out-of-pocket expenses for the year and three months is £43 14s. 5d. This covers petrol, oil, grease, brasso, and other sundries, also tyres, in reference to which I may say I have still in use a serviceable set and two repaired covers, at least good for many miles, for the front wheels. This works out at 1.3d. per mile; and, seeing that I ran the car from the first as a novice, the result is exceedingly satisfactory. In addition, I had a man for cleaning and washing, but only that my work is so heavy I could easily do this myself. His wages are not included, as he does gardening and other work as well. With regard to depreciation, I would consider 25 per cent. ample, as at the end of five years—say, doing 4,000 to 5,000 miles a year—the car should have a very decent second-hand value. My cost is much less than horses, and the comfort and convenience of the car not to be compared with them.

LITERARY NOTES.

Malaria is the title of a new international journal whose scope is indicated by its name. It will be published quarterly by J. Ambrosius Barth, of Leipzig. The editor is Dr. C. Mense, of Carlsbad. He will have the advantage of the co-operation of Professor Ronald Ross in England, Dr. MacCallum, of Baltimore in the United States, Dr. Nocht in Germany, while France will be represented by Dr. Sergent, of Algiers, and Italy by Professor Angelo Celli. The yearly subscription will be 20 marks.

The publication of a work entitled *Essai sur la Société Médicale et Religieuse au XII^e Siècle*; Gilles de Corbeil, *Médecin de Philippe Auguste et Chanoine de Notre Dame, 1140-1224*, by M. C. Viellard, is announced. Professor Ch. V. Langlois contributes a preface. The book is published by Honoré Champion, of Paris.

Reference was made in the JOURNAL of January 23rd to the difficulty sometimes experienced in tracing quotations familiar to every one to their source. As an instance, *Quos Deus vult perdere prius dementat* was cited, with Dr. Birkbeck Hill's suggestion that it is probably a rough translation of a fragment of Euripides. As some of our readers are keen in this kind of literary chase, the following note by Malone may be of interest. We quote it as it is given in the edition of Boswell's *Life of Johnson*

published by J. M. Dent in his series of "Temple Classics":

Mr. Boswell was furnished by Mr. Richard How, of Apsley, in Bedfordshire, as communicated to that gentleman by his friend Mr. John Pitts, late Rector of Great Brickhill, in Buckinghamshire:

'Perhaps no scrap of Latin whatever has been more quoted than this. It occasionally falls even from those who are scrupulous even to pedantry in their Latinity, and will not admit a word into their compositions which has not the sanction of the first age. The word *demento* is of no authority, either as a verb active or neuter. After a long search for the purpose of deciding a bet, some gentlemen of Cambridge found it among the fragments of Euripides, in what edition I do not recollect, where it is given as a translation of a Greek Iambic:

'Ο θεός θελει απολεσαι πρωτ' αποφρονειν.

"The above scrap was found in the handwriting of a suicide of fashion, Sir D. O., some years ago, lying on the table of the room where he had destroyed himself. The suicide was a man of classical acquirements: he left no other paper behind him."

Another of these proverbial sayings,

Incidit in Scyllam, cupiens vitare Charybdim,

I some years ago, in a note on a passage in *The Merchant of Venice*, traced to its source. It occurs (with a slight variation) in the *Alexandris* of Philip Gualtier (a poet of the thirteenth century), which was printed at Lyons in 1558. Darius is the person addressed:

Quo tendis inermem,

Rex periture, fugam? nescis, heu! perditte, nescis

Quem fugias: hostes incurris dum fugis hostem

Incidit in Scyllam, cupiens vitare Charybdim.

The author of this line was first ascertained by Galeottus Martius, who died in 1476; as is observed in Menagiana, vol. iii, p. 130, edit. 1762. For an account of Philip Gualtier, see Vossius, *De Poet. Latin.*, p. 254, fol. 1697.

A line not less frequently quoted than any of the preceding, was suggested for enquiry, several years ago, in a Note on the *Rape of Lucrece*,

Solamen miseris socios habuisse doloris.

But the author of this verse has not, I believe, been discovered.

With reference to the "Greek Iambic" above quoted we cannot say with Holofernes, "Ho! Ho! I smell false Latin": but it seems to us, in the words of Launcelot Gobbo, to have "a kind of smack." We give it as it is printed, but we may point out that it does not scan and cannot be construed. We are informed by a learned clerk of Oxford that there is no such word as *anopheva*. It is suggested that the line is a bad attempt to translate *Quem Deus vult perdere*, etc.

The fact that houses may be infected with diseases, one tenant after another dying of the same malady, was noticed as long ago as in the fifteenth century. Messer Agnolo Pandolfini, a rich merchant prince of Florence, in his treatise "Del Governo della Famiglia," quoted by Mrs. Oliphant in her *Makers of Florence*, thus advises his sons as to the taking of a house, giving them as an example his own experience:

I chose a house in a good neighbourhood and well-known street, where honest citizens lived of whom I could without danger make friends, while my wife found good company among their wives. And I informed myself who had lived in it in times past, and inquired whether they had been healthy and fortunate. There are certain houses in which, it would seem, no one can live happily.

To Guy's *Hospital Gazette* of December 26th, 1908, some interesting reminiscences of Thomas Addison are contributed by Sir Samuel Wilks. He says that when he first entered Guy's in the early Forties of the last century Addison was the most notable man there. It was at once apparent that he was a leader of men. It was a real treat to hear Addison talk, often adorned with a Latin quotation, as his scholarship was good, and with an occasional outbreak of oratory. When Jenner demonstrated the absolute difference between typhus and typhoid fever, Addison was loth to admit it, and it is interesting to learn that Gull took a considerable time to give it his full adhesion. Addison was one of the physicians of his day to adopt Laennec's method of physical examination of the chest. An elder colleague of Addison spoke of the stethoscope as the new playingthing, just as leaders of the profession at a later date called the laryngoscope a physiological toy. Addison's dogmatic manner was contagious, for Sir Samuel Wilks tells us that he remembers hearing at one of the chief medical societies when a young aspirant to fame displayed some conceit in describing a case, a remark to the effect that Guy's men thought themselves the *crème de*

la crème. He thinks this opinion was a general one at the time, and he is of opinion that it may be as beneficial for an institution to have a little conceit of itself as for an individual to think well of himself. Sir Samuel Wilks would evidently join in the prayer of the Scots minister, "God, gie us a guid conceit o' oorsels." Addison had been a colleague of Bateman at the public dispensary, and was a great authority on skin diseases. This doubtless helped to prevent his overlooking the discoloration of the skin which is the principal outward and visible sign of the disease which bears his name. Notwithstanding Addison's power over others he was a man of nervous temperament, subject to fits of despondency. This led him to resign his hospital appointments while still in the vigour of life. It was felt to be such a loss that a deputation headed, Sir Samuel Wilks thinks, by the late Dr. Galton, waited upon him to urge reconsideration of his decision. Addison's answer was, "My work is over; I have left it for others." He left London, and not long afterwards passed beyond that bourne from which no traveller returns. He was born in 1793 and died in 1860.

Dr. Farquharson, the absence of whose genial personality from Parliament, if it has not exactly eclipsed the gaiety of nations, has at any rate added to the dullness of the House of Commons, lately delivered an address in Aberdeen on the humour, phrase-making, caricature, and oratory of that assembly. As illustrations of the humour of the House of Commons he quoted a number of "bulls." Among these were: "Mr. Speaker, will you allow me to recapitulate what I had intended to say?" "The right hon. gentleman shakes his head, but I am very sorry to hear it"; "Mr. Speaker, I think I see a noise"; "Certain officials are hide-bound with red tape"; "The keys of the Irish difficulty were not to be found in the empty pockets of the landlord"; "It is a lie, Sir, and it is high time we nailed this lie to the mast"; "The present state of affairs is enough to make a man commit suicide or perish in the attempt"; "Mr. Speaker, I smell a rat, I see him floating in the air, but mark me, Sir, I will nip him in the bud"; "The apple of discord has been thrown into our midst, and if it is not nipped in the bud it will burst into a conflagration which will deluge the world"; "You may depend upon it that the pale face of the British soldier is the backbone of the Indian Army." Dr. Farquharson had apparently forgotten Lord Cross's memorable statement that he "heard a member smile," and Castlereagh's still more memorable declaration that he was about to "embark on the chief feature on which this question hinges." All who knew Dr. Farquharson, either as physician or as legislator, and in particular many members of the British Medical Association, in which he was at one time a prominent figure, will, we are sure, join us in wishing the genial Laird of Finzean many years of happiness in his mountain home.

One of the most impressive and picturesque sights that Florence offers to a stranger is a procession of the *Misericordia*. But probably few of those who have ever seen the black silent figures carrying their burden through the crowded streets of the city have a clear idea of their origin, which affords one more proof of the wonderful charity which flourished side by side with the most brutal indifference during the middle ages. The confraternity was founded in the thirteenth century by a Florentine porter, Pietro Borsi, with the twofold object of employing the spare time and reforming the vices of his fellow-porters whilst they were waiting for jobs in the Piazza of San Giovanni. Borsi first persuaded them to fine each other for swearing, and then with the proceeds to buy litters for the use of the public, each porter in his turn giving his services in carrying the sick and wounded to the hospital and the dead to the burial. In those troubled times, when street fights were things of daily occurrence, the brothers had plenty of opportunity for their charity, and the confraternity grew and developed. The Brothers now often nurse the sick in addition to their other labours, but the institution remains the same, and is still flourishing in Florence. All classes from the highest to the very lowest belong to it, taking their turns when summoned by their bell. The long black robe worn by the Brothers, which disguises them as completely as a domino, is used to prevent their ever working upon the gratitude of their patients, from whom they may only accept a drink of water in recompense of their services.

Medical News.

A SWISS Neurological Society has been formed, the head quarters of which are at Zürich. The President is Professor von Monakow.

A LAW making compulsory the pasteurization of all milk and milk products, other than those from cows which have passed the tuberculin test, came into force in Chicago on January 1st.

THE discussion on ulcerative colitis at the Medical Section of the Royal Society of Medicine has been adjourned until Wednesday, February 10th, at 5.30 p.m. The discussion will be continued by Sir Patrick Manson.

SIR JAMES CRICHTON-BROWNE, Treasurer of the Royal Institution, announces that the sum of £10,000 had been anonymously and unconditionally placed at the disposal of the managers for the purposes of the institution by a lady.

THE anniversary dinner of the Medical Society of London will be held at the Whitehall Rooms, Hôtel Métropole, on March 10th. Further particulars can be obtained from the Secretary, 11, Chandos Street, London, W.

A COURSE of lectures and demonstrations on the feeding of infants will be given at the Infants' Hospital, Westminster, by Dr. Ralph Vincent, on the afternoons of Tuesday, Thursday, and Friday during next and the following week.

THE annual oration before the Hunterian Society will be delivered by Dr. Rawes on Wednesday, February 10th, at 8.30 p.m., in the theatre of the London Institution, Finsbury Circus. The title is *Psychiatry: a Retrospect*. All members of the medical profession are invited.

ON the recommendation of the Morison Lecturer, the Treasurer of the Royal College of Physicians of Edinburgh has awarded the 1908 Morison medals for meritorious attendance on the insane, along with the usual premiums, to Mrs. Mary Gandie, Royal Asylum, Montrose, and Mr. Donald Munro, Inverness District Asylum.

AT a meeting of the Cold Storage and Ice Association to be held at the Royal Society of Arts, Adelphi, at 7.30 p.m. on Tuesday next, Mr. C. J. Tabor will read a paper on the preservation of food by artificial refrigeration; among the subjects discussed will be bone taint, the effect of refrigeration on the fat cells of fish, on poultry, and on goods stored in a bad condition.

THE Council of the British Medical Association, on the recommendation of the Medico-Political Committee, has appointed a special subcommittee, consisting of Dr. J. A. Macdonald, Mr. H. W. Armit, Dr. E. R. Pothergill, Dr. C. E. Haslip, Dr. E. H. T. Nash, and Mr. T. Jenner Verrall, to report on the proposed establishment of the central church council for the diocese of London, and to consider the whole subject of spiritual healing.

H.R.H. THE PRINCESS OF WALES has kindly consented to receive purses for the National Hospital for the Paralysed and Epileptic some time during the autumn. These purses will be for the Jubilee Fund, for which over 500 collections are being made throughout the country, some by former patients and pensioners of the hospital. The Duchess of Albany is President of the Executive Jubilee Committee, which hopes to raise £50,000. A portion of this sum will be devoted to an extension of premises, the building of which began a few days ago.

THE meeting at which the claims of the British Medical Benevolent Fund to the support not only of the profession but of the public will, we may remind readers, take place at the Royal College of Physicians of London on Tuesday next, at 5 p.m. The chair will be taken by Sir John Tweedy, President of the Fund, and an address will be delivered by the Bishop of Oxford, son of the late Sir James Paget, at one time president of the Fund. Among other speakers will be the President of the Royal College of Physicians of London.

THE election of Professor S. Kitasato, Director of the Infectious Diseases Institute at Tokyo, to the Honorary Fellowship of the Royal Society, was made the occasion of a dinner given in his honour by a number of his pupils and friends. Congratulatory addresses were delivered by Professor Kitajima and Dr. T. Takaki, Director of the Formosan Medical Institute, who said that whatever had been done for the improvement in public health in Formosa should be credited to Professor Kitasato, under whom he had studied bacteriology. It may be mentioned that the document in which the honour bestowed on Professor Kitasato was conveyed to him was in Latin.

British Medical Journal.

SATURDAY, FEBRUARY 6th, 1909.

THE THERAPEUTIC EFFECTS OF RADIUM.

THE question of the hour in medicine is the healing virtue of radium. Whether it will, like so many other things in the domain of therapeutics that come like shadows, so depart, fade away like Hans Breitmann's "barty" into the *Ewigkeit*, remains to be seen. But whatever be its fate it has not, like the gem of purest ray serene of which Gray sings, been left in the dark unfathomed caves of the unknown; it has made its entrance on the stage of medical life in a glare of publicity of which there are few instances on record. Last week an amusing and unedifying example of too "up-to-date" journalism was shown by the London Press. An announcement of the foundation of a radium institute which was wrong in nearly each and singular particular was made, with every appearance of authority, in all the newspapers. We were able to give the correct version of the facts. As far as we know, not one of the papers, which had evidently been victimized by some parties interested in creating a "boom," offered any apology for a piece of carelessness which caused serious annoyance in various quarters, and which might have done something to imperil the success of an enterprise that may possibly have a great future before it, and, at any rate, ought to be allowed a fair field for its development. The error was indeed corrected, but without any of the pomp of journalistic heraldry with which it was announced. Therefore, for the sake of any of our readers who may have been misled by the announcement in the newspapers, and who may have overlooked the statement made in the JOURNAL of last week, we think it well to repeat that the Radium Institute is to be known simply by that name, and that there has been no question of granting it a Royal Charter. It is understood to be founded in accordance with the wish of the King, and the means of carrying the scheme into effect have been supplied by Lord Iveagh and Sir Ernest Cassel. It is to be altogether independent of the Imperial Cancer Research Fund or of any other institution. A site has been secured in the neighbourhood of All Souls' Church, Langham Place. The committee under whose direction it will be conducted consists of Sir Frederick Treves (chairman), Sir Lauder Brunton, Sir Malcolm Morris, Sir William Ramsay, Professor Sir J. J. Thomson of Cambridge, and the Hon. R. J. Strutt. The services of a highly competent man as medical director have already, we believe, been secured. Some time must, of course, elapse before the new institution is in working order. It is intended to charge suitable fees to those who can afford them; for the cost of radium is very great, and owing to causes which need not be discussed here it has lately risen to a degree that makes it difficult to procure a sufficient supply. The justification of the existence of the Radium Institute lies in this fact; for under existing conditions it is practically impossible for individual medical men to obtain enough for use in any but the smallest way. It will be the special

function of the new institute to determine the therapeutic potentialities of radium under strictly scientific conditions and on a scale sufficiently large to afford a solid basis for a final judgement. It is an interesting experiment, and the profession will watch its progress and issue with interest.

The physical and chemical properties of radium are fully described in a special article published at page 347. Here we are concerned only with its therapeutic effects. That radium has an irritant and caustic action on animal tissues was discovered by accident. The idea of applying it in the treatment of growths, malignant and other, was a natural inference. For two or three years past a Radium Institute has been in existence in Paris, and to Dr. Louis Wickham and his collaborator, Dr. Degrais, we are chiefly indebted for what is known about its therapeutic action.¹ They claim for radium the following effects: (1) The modification of diseased tissue, the promotion of cicatrization and cure of morbid conditions, with or without previous ulcerative destruction; (2) analgesia; (3) an apparent bactericidal action. The modifying action on morbid tissues varies greatly. Thus, a warty epithelioma is more resistant than the ulcerative form of the disease, or than lupus tissue. The analgesic properties of radium are most marked in superficial pain, hyperaesthesia, or itching. In deep-seated pain its effect was uncertain. Its bactericidal power has been successfully tested on staphylococci and gonococci. To the Medical Congress held at Rheims in August, 1907, Dr. Wickham presented the results of a study of the therapeutic effects of radium extending over several years, and comprising 1,500 applications made in 1,100 cases. His experience led him to the conclusion that it has a beneficial action in certain kinds of skin disease—dry, chronic, and localized in character, such as certain eczemas, certain forms of neurodermatitis, lichen, psoriasis, vascular and pigmented naevi, tuberculous lesions, and cutaneous epithelioma.

It is in the treatment of cancer that the greatest interest will be felt in regard to the possibilities of radium. Wickham and Degrais confirm the conclusion arrived at by M. Danlos that it affords the best means of dealing with small caucroids. They go beyond this, and claim to have practically cured cancer of the face. "In all cases," they say, "one obtains a surface of repair which is smooth, on the same level as the surrounding healthy tissues; the white discoloration soon takes on a normal tint; to the touch it gives a sensation of appreciable suppleness in cases where the lesions were situated about orifices, and there practically never occurs retractile cicatrization. So perfect is the scar that it is sometimes difficult to find the traces of the former lesion." Wickham holds that radium has a selective action on cancer cells, and that in some cases it can modify or destroy them without producing any visible lesion. A summary of their results and of those of Dr. Dominici was given in the BRITISH MEDICAL JOURNAL of January 23rd, p. 242, where the method of application is described. Reference to the most recent results obtained by Wickham is made in the address by Sir Frederick Treves, which is published in this issue of the JOURNAL. It should be stated that Dr. Wickham, though not perhaps unnaturally optimistic in his estimate of the therapeutic properties of radium, is careful not to offer it to the profession as a cure for

¹ See communications to the International Medical Congress of Dermatology held at New York, September, 1907; to the Congrès de Médecine held at Rheims, October, 1907; and to the Paris Académie de Médecine, January, 1908.

all forms of cancer, or an infallible cure of any. He thinks it a useful addition to the x -ray treatment, to surgical procedure, and to the use of caustics. He cherishes a hope that means may be discovered of making it possible to apply radium emanations to the deeper parts of the body.

At the Congress of the International Surgical Society held at Brussels in September, 1908, Dr. James H. Sequeira gave his experience of the treatment of cancer by radium. He has found that the cases in which radium can be usefully employed are few. "It is," he says, "impossible to apply it to any large area "on account of the small quantity at command." He has used it chiefly in conditions in which it is impossible or undesirable to apply the x rays, for instance, in the treatment of small ulcers of the nose and other cavities, but otherwise he does not find that he can do more with radium than he can with the x rays.

Sir Malcolm Morris and Dr. Ernest Dore state that in the treatment of certain forms of malignant disease radium has undoubtedly a place, and has succeeded where x rays have failed.¹ The reason of this is because it can be applied in small cavities not directly accessible to the x rays, and in situations, such as the neighbourhood of the eye, where the use of rays is inadvisable. In other forms of malignant disease radium, whether applied externally or embedded in the tissues, has not been of much use. Cases of rodent ulcer cured by radium have been recorded by Mackenzie Davidson, Hartigan, Holzknecht, and others.

Enough has been said here, and more will be found in Sir Frederick Treves's address, to make out a *prima facie* case for radium as at least a useful adjunct in the treatment of cancer. But so far there is little to prove that it is more effective than the x rays, and these, we know, often fail after what looks like a brilliant initial success. While some believe radium to have a selective action on cancer cells, others see nothing to justify this inference. It is now well known that in some cases a process occurs in epithelioma which leads to spontaneous cure. This fact must never be lost sight of in estimating the results of treatment of cancer. Again, assuming that radium has all the virtues ascribed to it by those who have used it, the inevitable question rises to the mind, How long will the apparent cure last?

To put the matter briefly, the problem which the Radium Institute has before it is this: Is radium a new healing force or merely a very powerful and penetrating caustic?

THE REGISTRAR-GENERAL'S REPORT.

The annual report of the Registrar-General for England and Wales is usually one of the most interesting Blue Books of the year, for it throws much light not only on the prevalence of various diseases, but also on many social questions: it is true that the trustworthiness of some of the data has been called in question, but as to the accuracy of the broad facts there can be little or no doubt. A short statement of the principal points in the seventieth annual report—that for 1907—is published in the SUPPLEMENT, but we may here call attention to one or two matters of general interest.

In the first place, it appears that the decline in the

mean annual rate of increase of population which has been observed during the last thirty years has continued, the rate being 11.27 in 1907, as compared with 11.69 in the previous year, and with 12.10 in the quinquennium 1901-05. The increase or decrease of population is governed by two factors—the balance between births and deaths, and the balance between emigration and immigration. So far back as trustworthy statistics extend there has always been an excess of births over deaths, and an excess of emigrants over immigrants. The natural increase is the excess of births over deaths, and the diminished rate of increase of the population is due to the birth-rate having declined more rapidly than the death-rate. The birth-rate reached its highest known point in 1876, when it equalled 36.3 per 1,000 of population; since then it has, with slight fluctuations, steadily fallen, and in 1907 reached the lowest point on record, 26.3, which is 0.8 below that recorded in 1906, and 2.1 below the average for the ten years 1897-1906. As will be seen from the statistics published last week (page 310), the rate in 1908 was 0.2 per cent. higher than in 1907.

The proportion of marriages among marriageable persons in the population has decreased since 1876 in the proportion of 103 to 93. The proportion of spinsters in the marriageable population has always been smaller than the proportion of bachelors, but appears to be tending to increase. Age of marriage has undoubtedly an influence on the birth-rate, but, as is pointed out in the report, the ages of men at marriage are, so far as concerns the growth of the population, of much less importance than the ages of women at marriage. The fact that child-bearing is practically limited to the period between the ages of 15 and 45 years, and that the fertility of married women is highest at the earlier age groups, makes it evident that any great alteration in the ages of women at marriage must necessarily have important effects on the birth-rate. Men and women intermarry at all ages; but, taking the records for the ten years 1893-1907 as an example, over 40 per cent. of the bridegrooms, and nearly 60 per cent. of the brides, were at their first marriage under 25 years of age, while the mean age at marriage in those ten years averaged 26.9 years for all bachelors and 25.3 years for all spinsters.

The number of deaths attributed to cancer has, as is well known, shown for many years a very marked and steady increase. As it is a disease of maturity and age, the best way of measuring its increase is to compare the mean death-rate per million living at ages 35 years and upwards. In the *Decennial Supplement* Dr. Tatham showed that this rate had risen from 1,834 in the decennium 1881-1890 to 2,316 in 1891-1900; he now adds that the corrected rate was 2,645 in the quinquennium 1902-1906 and 2,734 in 1907. A comparison with earlier statistics involves many fallacies, one of the chief being, no doubt, that diagnosis is more careful than formerly—a view borne out by the fact that the statistical increase is shown to be largely due to the more frequent detection of internal cancer at an operation or on *post-mortem* examination. That this is not the whole explanation seems fairly clear for several reasons. Among these is the fact that the increase has gone on apparently at much the same rate during the last few years, although there has not, so far as we can judge, been any corresponding increase in the readiness of surgeons to operate in suspected cases of internal cancer. The statistics have for years past indicated that the deaths from cancer at ages over

35 years are increasing more rapidly among males than among females. In the ten years 1881-1890 there were 60 deaths among men to 100 deaths among women; in the ten years 1891-1900 the proportion had risen to 69; in the five years 1902-1906 to 77, and in 1907 it was 79. In the seven years which ended in 1907 there died from cancer, in round numbers, 85,000 men and 123,000 women; the greater number of deaths among women was accounted for entirely by the fact that the generative and mammary organs of women are much more frequently the seat of disease than are those of men. In the period of seven years ending with 1907 the recorded deaths of males from malignant disease, affecting other than the generative and mammary organs, were equal to a rate of 730 per million, whilst the deaths of females with the same reservation did not exceed 594 per million. During this same period of seven years of every 10,000 males dying of cancer, 2,157 suffered from cancer of the stomach, while of the same number of women dying of cancer 2,241 suffered from cancer of the uterus. Further analysis of the statistics shows the very large part which cancer of the gastro-intestinal system plays in producing the mortality from the disease in both sexes. Among males the organ most frequently invaded was the stomach, which was the seat of disease in nearly 22 per cent.; the liver and gall bladder were invaded in nearly 15 per cent. of the whole, the rectum in 10 per cent., and the intestines in 8 per cent. Taken together, the parts here specified were attacked in more than half the cases. Among females, while the generative and mammary organs were affected in more than two-fifths of the total cases, a further two-fifths was contributed by affections of the stomach, liver, intestines, and rectum taken together.

When commenting in the *Decennial Supplement* on the fact that the total death-rate from all forms of tuberculosis had within the previous forty years fallen by nearly 38 per cent., Dr. Tatham drew attention to the fact that according to the statistics available, considerable changes had taken place in the fatality of its several forms. Whilst, on the one hand, tuberculosis of the lung, the brain, and the peritoneum is now less destructive than formerly, on the other hand, there has been a considerable increase in the fatality of the other manifestations of tuberculosis, including general tuberculosis and scrofula, as well as tuberculous affections of the bones, joints, and other organs not mentioned above. In the ten years 1891-1900, out of every hundred deaths from tuberculosis 69 were ascribed to phthisis, 11 each to tuberculous meningitis and tuberculous peritonitis (formerly called "tabes mesenterica," and 9 to other forms of tuberculosis. During the same period the death-rate from tuberculosis was 2,010 per million of the population, and 11 per cent. of the deaths from all causes were due to this disease. In 1907 the death-rate was 1,605 per million, and represented 10.7 per cent. of the mortality from all causes. It appears that of the total number of deaths from tuberculosis at all ages 18 per cent. were those of children under the age of 5 years, the rate for boys being 277 and for girls 230 per million living. The mortality-rates from phthisis show a decline at practically every period of life as compared with the previous quinquennium, although it has been rather greater in the country than in the town.

The number of deaths attributed to alcoholism and delirium tremens was 2,201 (1,328 males and 873 females), but Dr. Tatham again calls attention to the

fact that the deaths actually assigned to these causes form an imperfect measure of the mortality caused by alcoholic intemperance, the best available indication being probably furnished by the combined mortality from alcoholism and cirrhosis of the liver. This mortality, which has been increasing for many years, reached its highest point in 1900, when the rate was 623 per million men living above 25 years of age, and 449 among women above that age. In the seven succeeding years there was a steady decline, equal in the case of men to 24 per cent., and in that of women to 19 per cent.

Puerperal sepsis accounted for the deaths of 1,465 women in 1907, and 2,055 deaths were attributed to other diseases or accidents of pregnancy or childbirth. Of this total, 102 deaths were assigned to abortion or miscarriage, 70 to puerperal mania, 449 to puerperal convulsions, 608 to placenta prævia or flooding, and 826 to other accidents of pregnancy or childbirth. In 224 out of the 826 deaths last mentioned the cause was precisely stated—this was, ectopic gestation in 74 instances, ruptured uterus in 26, inversion of that organ in 7, deformed pelvis in 27, adherent placenta in 27, conditions necessitating Caesarean section in 16, and malpresentation in 6. Of the 2,055 cases in this category, 352 were further complicated, the complicating cause being embolism in 178 instances, diseases of the heart or blood vessels in 48, kidney disease in 43, bronchitis or pleurisy in 27, and pneumonia in 6. These 2,055 deaths, added to those from the puerperal septic diseases, numbered 3,520, and were equal to a rate of 3.83 per 1,000 births. In the ten years immediately preceding, the average proportion had been 4.39 per 1,000.

ALCOHOL AND CHILDREN.

THE effect of alcohol on the mind of the child has recently been very fully discussed by Dr. Leopold Lang, of Vienna,¹ who has arrayed a considerable body of evidence, proving, first, that drunkenness in the parents tends to produce grave mental defect in the offspring, whether one or both parents are intoxicated only at the time of conception or are habitual drunkards; and, secondly, that the drinking by juveniles of alcoholic liquors, even in moderate doses, seriously affects their mental capacity and development. These two questions belong to different departments of inquiry and differ in complexity, the first being a biological question beset with great difficulties and impossible of solution by statistical methods alone, whilst the second does very largely admit of statistical proof if supplemented by psychological observation and experiment. This difference in the orders to which these two questions belong is reflected in the opposing views held regarding the first question, whereas on the second there is, we believe, general agreement amongst medical men.

In support of the ancient belief that children conceived in drunkenness are, as Burton said, "never 'likely to have good brains,'" Dr. Lang adduces the evidence of Lippich, who found that out of 97 such children only 14 were normal; of Bourneville, who out of 1,372 idiot children in whom the circumstances were known, found that 321, or 23.4 per cent., were so conceived; and of Bezzola in Switzerland, who found that of 68 idiot or profoundly imbecile children, the conception times fell, in one-half the cases, in New Year, Carnival, or Vintage—all of them periods of alcoholic excess—

¹ *Die kindliche Psyche und der Genuss geistiger Getränke*. By Dr. Leopold Lang. Vienna: Josef Salfar. 1907. (Roy. 8vo, pp. 41. M. 1.40.)

whilst the conception times of the other half were evenly distributed over the remaining thirty-eight weeks of the year. These figures referred only to one canton, that of Grisons. To broaden the basis of his inquiries, therefore, Dr. Bezzola plotted a conception curve for the whole 8,196 weak-minded children in Switzerland who in the year 1897 were unable to attend school on account of their mental condition, and contrasted this with a general conception curve obtained from almost a million birthdays of the ordinary population. The result, Dr. Lang says, proved highly significant. In February the curve of the weak-minded reached far above the general curve, sank slightly in March and then rose again in April, to reach a first maximum which lasted up to June. Thereafter the curve sank and remained low during the summer months—periods of hard work with no time for excessive indulgence—and then rose steeply in October, to fall again below the general curve in the last two months of the year. February, therefore, in which falls Carnival; April to June, the chosen months for weddings and feasts; and October, Vintage time, showed notable elevations of the weak-minded over the normal curve, and satisfied Dr. Lang of the truth contained in the observation of an Austrian elementary school master, who said that when in the first class they found many feeble-minded scholars, they knew that six years before there had been a good wine year. Fluctuations exactly similar to those recorded by Bezzola were observed by Hartmann in plotting the conception curve of 214 criminals in Zurich. Mainly on the above-mentioned grounds Dr. Lang bases his belief in the special poisoning of germ cells—what Forel has termed blastophthoria—by alcohol at the time of conception, a belief which was perhaps embodied in the Spartan nuptial laws of Lycurgus.

On the wider question of the habitual and excessive consumption of alcohol producing a defective progeny, Dr. Lang does not bring forward any new evidence, but quotes the well-known statistics of Bourneville, who showed that of 2,891 juvenile first admissions (idiocy, epilepsy, weak-mindedness, and hysteria) to the Bicêtre and Vallée, 43.2 per cent. had drunken fathers; 3.6 per cent. drunken mothers; in 1.9 per cent. both parents were drunken, and in 51.3 per cent. the parents were abstainers. According to the statistics of Bleuler of Zurich, 70 per cent. of the epileptics of Burghölzli Asylum had an alcoholic heredity; Lunier asserted that 50 per cent. of the idiot and imbecile children of France had drunken parents, and much evidence supporting the opinion as to the baneful action of alcohol has been published by Schmid-Monnard, Fletcher Beach, and Hitzig. Dr. Lang recalls the fact, frequently commented upon by other writers, that in Norway, where in 1816 the distillation of spirits was declared free, drunkenness subsequently greatly increased, followed in the years 1825 to 1835 by an increase in the number of idiots amounting to 150 per cent.; whereas after the restrictions placed upon the consumption of spirits in that country the number of idiots fell in ten years by more than 16 per cent., notwithstanding an increase in the population of 14 per cent.

In discussing the effect of moderate drinking by juveniles, Dr. Lang gives the results of considerable numbers of experiments upon students and others as to the mental output of work with alcohol and without. Most of these experiments, conducted by Drs. Führer, Smith, Demme, Rudin, Kürz, and others, are already widely known and do not require further

mention, as they only corroborate what is already well known from investigations in this and many another country—namely, that alcohol, even in moderate doses, acts as an immobilizer of nervous functions, beginning with the highest and latest acquired, enfeebling the power of voluntary attention, retarding the power of calculation, and reducing ideal associations from logical and complex to less complex associational levels. Dr. Lang, however, gives one or two particulars worthy of notice. The experiments with students showed that on the day following the drinking of small quantities of alcohol, even though they appeared to themselves to have slept better than usual, the output of work was less than the normal. Another interesting point concerned the relative number of marks earned by school children, arranged according to whether they never drank alcohol, only exceptionally, or every day. The tables furnished by Dr. Lang, taken from the results of Dr. Bayer of Vienna and those of the Association of Abstinent Teachers in Holland, give parallel results. They show that in the "very good" and "good" classes the abstainers head the list by considerable proportions; in those giving "moderate" or "sufficient" results the proportions are about equal, and in those giving "inadequate" or "bad" results the proportion of those who drink is more than twice as great as of the abstainers. A surprising fact related by Dr. Lang is the considerable proportion of school children in Holland, Austria, and Germany who drink beer, wine, and even spirits. To take only one example: Inquiries in Vienna disclosed the fact that in that town more than 53,000, or over 32 per cent., of the whole number of school children, regularly drank beer; nearly 20,000, or over 11 per cent., wine; and nearly 6,000, or 3.5, spirits. To what extent juvenile drinking obtains in our country we do not know. Accurate information on this point would be valuable, particularly if at the same time the educational results could be obtained and compared from this point of view. We imagine, however, that in this country juvenile drinking is of infrequent occurrence, and that in this matter, at least, we can say, "Let the galled jade wince, our withers are unwrung."

THE ACCURACY OF THE MEDICAL REGISTER.

WE draw the particular attention of all registered medical practitioners to the letter from the Registrar of the General Medical Council, which is published at p. 369. It is very much to the interest of the medical profession that the *Medical Register* should be accurate, and Section XIV of the Medical Act, 1858, empowers the Registrar to write a letter to any registered person, addressing him at his address on the *Register*, to inquire whether he has ceased to practise or has changed his residence. If no answer be returned to this letter within a period of six months, the name may be erased from the *Register*. When a special effort was made some years ago to comply with this section, we remember that we afterwards received a number of complaints from medical practitioners who found that their names had been erased. On Monday last circulars from the Registrar were addressed to every person whose name appeared on the *Medical Register*, except those belonging to the Royal Navy, Army, and Indian Medical Services whose names appear on the official lists of those services. It is important that every practitioner who has received the circular should

reply, and that any registered practitioner who may not have received the circular and who is not a member of one of the services mentioned should communicate at once with the Registrar of the General Medical Council, 299, Oxford Street, London, W. Notices have been sent to all the principal papers in London, in the provinces, in Scotland, in Ireland, and in the Colonies, drawing attention to the issue of the circular. The expense of issuing the circular is estimated at about £300, but it is believed that the money will be well expended, inasmuch as the result ought to be to make the *Medical Register* of 1910 absolutely accurate. It is, as we have said, in the interest of all medical men to respond promptly to the inquiry. The intention we understand, is to remove the name in every case in which an answer is not received within the stated period. It must be recognized that the General Medical Council is in this dilemma: either it must leave on the *Register* the names of persons of whom no trace can be found, and who, very possibly, may be dead, or it must remove these names although the person is alive. Of the two, the latter seems to be the less harmful procedure, for whereas it is always possible to restore a name which has been taken off, provided the identity is safeguarded, to leave on the *Register* the name of a man who is dead gives an opportunity for personation.

THE EMMANUEL MOVEMENT.

IN THE BRITISH MEDICAL JOURNAL of January 16th, p. 171, we showed that the statement made by the leaders of the so-called Emmanuel movement in Boston that it had the sanction of the leading neurologists in New England was incorrect. Since then we have received a letter from Professor Coombe Knapp, of Harvard, who had evidently not yet seen the article just referred to, in which he says that when the new movement was begun one or two neurologists of Boston were consulted and that they, thinking that the work was to be under medical control, gave a partial approval to it. Other neurologists of Boston were not consulted at all and most of them at the outset regarded the movement with scepticism. When its true character was known, even those who had given a partial approval protested, but their protest was disregarded and they were constantly quoted as advising and approving of it. Now, he says, every neurologist of standing in Boston has recorded his condemnation of the movement. This shows that the clerical healers lost no time in shaking themselves free from any medical direction. Already we have the interviewer and the snapshotter showing them at work. An illustration of their methods is given from personal observation by Mr. Ray Stannard Baker, who had an opportunity of watching the practice of the Rev. Lyman P. Powell, of St. John's Church, Northampton, Massachusetts. His method is simply suggestion with or without hypnotism. Speaking of those who seek counsel of the priestly healers, Mr. Powell says: "Our idea, of course, is to influence their subconscious 'lives': to replace their hopelessness and moral weakness with suggestions of power and virtue and strength. We do not need to produce a hypnotic sleep, except in rare cases, to reach this end. All that is required is a relaxation of mind and body, a repose, in which the deeper nature is open to suggestion. We don't know why it is, but if good thoughts and strong purposes are thus impressed upon the mind of a patient in times of repose, these good thoughts act upon and stimulate his life afterward. He is cured, sometimes instantly, of his sickness or his sin, but usually the treatments must continue for

"some time." It might have been foreseen that the vaulting ambition of spiritual healers would not allow itself to be confined within the vague domain of "functional" diseases. Mr. Baker says he visited "one of Mr. Powell's patients who was afflicted with a malignant internal growth and often suffered the most excruciating pain. She had been more or less bedridden for years and had taken all sorts of medicine for relief. Mr. Powell has been treating her now for many months, not promising a cure but merely freedom from suffering. The pain instantly disappears under his treatment, so that the patient rests in perfect comfort or is even able to get up and walk. In four or five days, however, the pain returns, and Mr. Powell gives another treatment. This summer a remarkable thing happened. Mr. Powell was away on his vacation for several weeks, and during a part of the time the woman suffered acutely; but on the day she heard that Mr. Powell was returning, so great was her faith in his power to bring relief that the pain stopt before he arrived. He is thus able to make the life of a suffering woman comfortable and even happy where it was formerly wholly miserable." Assuming all this to be true, one may wonder where religion comes in here: it is a plain case of simple faith in a man working its effect in a favourable medium. We are told that the religious element is to be found in "the quieting and hope-inspiring meetings of the church, where every one is looking on the bright side of life." Then there is "the important matter of confession. Before a patient can be successfully treated he must unburden his soul and let the minister who is treating him understand to the depths all the sources of his trouble. Without this it is impossible to begin anew"—and so forth. It may be pointed out that this doctrine lay at the bottom of a rule of the mediaeval Church that a doctor in charge of a patient suffering from an illness which threatened to become serious should give up attendance within three days unless the patient went to confession and received communion. That devotional exercises may be of help in some cases is unquestionably true; religion is hope, and hope is a powerful medicine. In this way anointing and laying on of hands may be serviceable by ministering to a mind diseased which is beyond the reach of medicine. But if "spiritual healing" is to do good, cases must be carefully selected for its application. Such cases are limited in number, and they all bear the same character of neurosis. One who, in Hamlet's phrase, knows the stops of an unstable nervous system can play upon it and sound it from its lowest note to the top of its compass. It is a dangerous power which should be exercised only with the utmost caution and under skilled supervision. We therefore solemnly warn those well-meaning clergymen and others that they are employing an instrument which, if misused, may have the most harmful effects on sufferers. History is full of the evils wrought by such means, and abundant evidence could be brought forward to show that spiritual healing is apt to degenerate into superstition, and from that into unspiritual imposture.

"ARTIFICIAL LANGUAGES."

WE have received a further communication from Dr. Sydney Whitaker complaining that we did not publish his letter in defence of Esperanto in full. We dealt with all the points in it that seemed to us of any importance. He repeats that we were guilty of a breach of the laws of grammar, and quotes the sentence which he thinks faulty. It is recorded that the father of Frederick the Great, once seeing a crowd of people reading a placard on a wall in Berlin, had the curiosity

to go near, and saw that it was a pasquinade on himself. He at once ordered it to be fixed lower on the wall so that it might be read more easily. In this spirit we quote the sentence which falls under the lash of the Esperantist Zeilus: "It [videlicet, language] is a "natural growth subject to modifications, as the people "whose means of expressing themselves it is, adapt "themselves to changes of environment, mode of life, "intellectual outlook, and moral conventions." We cannot see where Priscian's, or rather Lindley Murray's, head is scratched in this. Our blindness is like that of Teufelsdröckh, whose famous epiphon on a noble sportsman remained, he says, unengraved "for an "alleged defect of Latinity, a defect never yet fully "visible to myself." We have also received a letter from Dr. Major Greenwood, to whom our criticism seems superficial, and who finds our arguments unconvincing. We take leave to think that the superficiality is on the other side; and in regard to convincing, we can only say that the prosperity of an argument, like that of a jest, lies in the ear of him that hears it. Dr. Greenwood quarrels with our interpretation of Chaucer's lines about the prioress's talking French "after the scole of Stratford-atté-Bowe." He says the poet was ridiculing her pronunciation. No doubt he was, but the fact remains that Anglo-Norman French was at the date of the famous pilgrimage spoken at Court, and there was a well-known nunnery at Stratford-le-Bow where Chaucer meant us to understand that the lady had been educated. The point seems to us to help our argument rather than that of Dr. Greenwood. All we wished to show was that language inevitably changes, and that unless Esperanto is held by its devotees to be immutable and indefectible it must in time become altered. The vocabulary and pronunciation of English have altered to a marked degree within the last century, and to a considerable extent within the last thirty or forty years. A language which sprang from the mind of Dr. Zamenhof, as Minerva sprang full armed from the head of Jove, cannot escape the lot of ordinary human speech. The subject has been very fully discussed in the JOURNAL from both sides, and we would say to any other disputants who may feel moved to enter the arena:

Claudite jam rivos pueri: sat prata biberunt.

VAGINITIS FROM WATER.

AN acute vulvo-vaginal discharge in an adult is a very compromising malady, but it is recognized that dirty linen and dirty habits may cause the infection of the subject quite independently of sexual relations, and it has long been known that the vulvo-vaginitis of children, a disease usually far more acute than simple leucorrhoea in the adult, is thus propagated. Recent researches appear to show that staphylococcus infection is sometimes conveyed by the water used for washing and for vaginal injections. Van de Velde made cultures from 9 cases of acute cervical metritis associated with colpitis and vulvitis, and on subsequently examining the well-water the patients had used for their ablutions detected the same species of blastomycetes as he had discovered in the pus. Dr. Boshower of Haarlem,¹ has recently published a similar case of much importance, as the patient might have been deeply compromised by her malady. He was consulted by a young lady, aged 19, for a very acute discharge with all the objective and subjective features of gonorrhoea. As far as could be made out there was no reason to suspect gonorrhoeal infection. Boshower submitted specimens of pus from this case to Dr. Havelaar, Director of the

Municipal Laboratory of Haarlem. Great pains were taken to avoid all sources of error. The gonococcus could not be found. The pus contained in abundance the *Staphylococcus pyogenes albus*, which had the haemolytic properties of that species. Water taken with suitable precautions from the well used by the patient for washing yielded pure cultures of the same microbe. It was found that two younger sisters of the patient, both little children, had previously suffered from vulvo-vaginitis; and Mendes de Leon in 1907 reported instances of that malady in which there could be no doubt that this staphylococcus was the infecting germ. Boshower remarks that ten years ago Hofmeier taught that genital infection not due to gonorrhoea was not rarely observed in nulliparae, and adds that with the knowledge to which we have attained since 1898 we can indicate with great certainty the line of travel of these infections and not rarely make clear their cause.

OLD AGE PENSIONS IN GERMANY.

THE HON. W. P. REEVES, formerly State Commissioner for New Zealand, who last year resigned that office to become Director of the London School of Economics and Political Science, delivered last Tuesday at the school a lecture on State-aided pensions for the poor. Germany, France, and Belgium, he said, afforded examples of contributory pensions, and Denmark, Australia, New Zealand, and the United Kingdom of limited free pensions. He expressed the opinion that all pension schemes in the future would belong to one or other class, since a system of free State universal pensions was not likely ever to be applied. The Belgian system of superannuation for the poor, provided by voluntary contributions with an added State donation, had encouraged thrift, but as it had yielded only an average pension of £3 a year the State had found it necessary to institute a system of free old age pensions for the utterly destitute. The greater part of the lecture was devoted to the system of compulsory insurance which has been in force in Germany for twenty-six years, and is applicable to men and single women earning less than £100 a year. Mr. Reeves pointed out that, as the funds were provided by equal contributions from employers and employed, the principle of the system was that of deferred wages, and it was a question whether thrift was encouraged by withholding 2 per cent. of wages. Professor Ashley had shown that of the 10,700,000 men insurable 8,857,000 were insured, and of the 5,800,000 women who were qualified to provide for pensions 4,524,000 were paying their contributions. The system provided for old age, sickness and accidents, and in 1907 nearly £30,000,000 was expended; of this £8,400,000 was expended in pensions to the aged and infirm. The State bore the cost of management, and added to every pension a bonus of £2 10s. a year. For the working of the system the wage-earners were divided into five grades: (1) Those who earned up to £17 10s. a year; (2) those who earned any sum between £17 10s. and £27 10s.; (3) those who earned between £27 10s. and £42 10s.; (4) those who earned between £42 10s. and £57; and (5) those who earned between £57 and £100. The lowest wage-earners paid seven-eighths of a penny a week for their old-age pension, and the highest wage-earners about 2½d. No special consideration was shown for a married man. The five grades of pensions were: (1) £5 10s. a year; (2) £7; (3) £8 10s.; (4) £10; and (5) £11 10s. If the labourer died after subscribing for 200 weeks his wife and children were entitled to receive what he had subscribed, but nothing more. The lot of the widows and orphans was one of the black features of the

¹ Infection Staphylococcique des Organes Génitaux. Rev. de Gyn. et de Chir. Abdom., vol. xii, September-October, 1908, p. 775.

system. A married woman could not qualify for an old-age pension. The amount of the weekly contribution was fixed for ten years. If the insurers, after having subscribed for not less than four years, broke down and were unable to earn wages, they were entitled to more generous treatment. If curable they were treated in State sanatoriums, and received temporary sickness pensions. If incurable they received a pension regulated by the number of years they had subscribed, and varying from a minimum of £5 16s. in the lowest grade for four years' subscriptions to £22 10s. in the highest grade for 50 years' subscriptions. The insurer began to pay his contributions at the age of 17, and for an old-age pension he had to subscribe 50 weeks a year for 24 years—1,200 weeks in all.

DEATH UNDER STOVAINE.

THE unfortunate incident of the death of an elderly patient under stovaine, injected subdurally to produce spinal anaesthesia for a necessary operation—the inquest on which is referred to on page 376—must apparently be added to the relatively very small number of fatal cases attributable to this valuable anaesthetic. The patient was 72 and a house painter, who, in addition to an enlarged prostate and its complications, had a degenerate heart and diseased lungs. The use of both chloroform and ether as general anaesthetics being contraindicated, and the safest of the known local analgesics was properly chosen, and sympathy is to be extended to Dr. MacCormac in the matter. No therapeutic agent capable of absolutely abolishing pain can it is to be presumed, ever be absolutely safe. In regard to spinal analgesia, over 5,000 cases collected by one investigator show only five deaths. Mr. Barker has recorded a series of 300 cases, and Messrs. Spencer and Houghton, Mr. McGavin, and Dr. Mill Renton a series of 50 each without a single fatal result and with hardly an untoward symptom. Experience shows that patients who take general anaesthetics badly, including the aged and alcoholic, usually bear stovaine well, and the absence of shock after even serious operation has been remarkable. In regard to a possible fright factor it is of interest to recall that in the first case selected for the administration of chloroform in the Edinburgh Royal Infirmary the patient died on the table, immediately after the first incision. It is fortunate for the future of chloroform that, owing to the unavoidable absence of Simpson, the anaesthetic was not administered. It is the rule in operating under local anaesthesia that the field of operation should be screened from the patient, and the custom to distract meanwhile the patient's mind by engaging him in conversation. It is doubtless one of the drawbacks of the method, especially in the presence of heart weakness, that the head must be kept raised in order to protect the medulla and its nerves from the influence of the drug. In view of the infrequency of ill effects after stovaine the present regrettable result may fairly be taken as an exception that proves the rule.

THE ARMY MEDICAL COLLEGE.

SIR ALFRED KEOGH, Director-General of the Royal Army Medical Corps, and the members of the Royal Army Medical College on Tuesday evening entertained at dinner Viscount Middleton, who, when as Mr. St. John Brodrick he was Secretary of State for War, founded the College. The chairman in proposing the toast of the guests, said that Lord Middleton had studied the subject of a medical service with an army in the field as it had not been studied since the days of Sidney Herbert. The College was established with the view of improving the early education of the army medical officer and of giving him the advanced and

special education which he required at various stages of his career. The College was also designed to undertake research into the origin and spread of military diseases. Already the admissions to military hospitals had been diminished, the death-rate in the army lowered, invaliding lessened, and recruiting improved. Lord Middleton, in expressing his acknowledgement, said that the fierce light which now beats upon a campaign affected the medical service even more than the combatant services, for the patriotic restraint which held men back from criticizing soldiers for losing lives impelled them with double force to make free with doctors for not saving them; it was never realized that it was only in very recent campaigns that the medical department had been allowed a say at all on anything but the actual care of sick and wounded. "Prevention is better than cure," and for every wounded man the medical officer could heal he could save a dozen lives by attending to the sanitation of the hospital, by proper selection of the sites for camps, and by the control of drinking water. The seven years which had elapsed since the South African war had been most important in the medical history of the British army: the number of medical officers had increased by 40 per cent., while the qualified candidates had since 1902 been double the number of commissions vacant. The College gave about six months of the most modern professional training to officers after seven years' service, and the Royal Army Medical Corps was no longer cut off from the companionship of the civil profession. In conclusion, Lord Middleton said that one of the causes which had spoiled every modern effort to reorganize the army was the want of continuity in the views of successive administrators. He urged the medical service of the army to avoid this pitfall.

A CIRCULATING LIBRARY OF HYGIENE.

DURING the last four years the members of women's clubs of Massachusetts have had in circulation a library of books on matters relating to health and hygiene. The result has been that a great public interest in personal and public health, and especially in the suppression of tuberculosis, has been aroused. It is believed, says the *Medical Record*, that no other one agent has had a more happy influence upon the public mind, resulting in legislative appropriations for the care of the tuberculous, the establishment of local antituberculosis and visiting nursing associations, and the foundation of day camps. It is proposed now to extend the library scheme to the country at large, and the General Federation of Women's Clubs will recommend that such a library be bought and circulated by the clubs.

PLAGUE IN THE AZORES.

THE last issue of the *Oporto Hospital Gazette* contains a lengthy account of plague conditions in the Azores, by Professor Sousa, head of the Bacteriological Laboratory in Oporto, who was recently sent out in charge of the medical mission to combat the outbreak. His letter is dated December 31st. The first task has been to divide the island of Terceira (to which apparently the plague is limited) into six districts, each under the charge of a separate staff and assistants. Disinfection brigades were also organized, special attention being directed to the parish of Sta. Barbara, the focus of the formidable outbreak of the pneumonic form of the disease. Rat brigades have been started, 40 reis (about 2d.) being paid for each rat, the animals being dropped into petroleum after being killed in order to avoid flea infection. The disease seems to have begun in June

and to have been especially marked in the Angra and Prai da Victoria districts. In the former, of 85 cases there were 50 deaths, and in the latter, of 107 cases 52 deaths. In Angra there were 40 cases of the pneumonic or septicaemic type, all of which proved fatal. The rats were found affected in all the parishes whence specimens had been received, and cats had also been found with abundant bacilli, in some cases, indeed, so abundant as to be spoken of as "indescrivable," which the phototype given in illustration fully bears out. Professor Sousa, however, does not seem to believe in the affection of the poultry, and describes the experiments that he made to infect them, but they were too restricted to be of much value. The Hong Kong experiments carried out by Dr. Simpson in 1902, apart from other evidence, conclusively shows that fowls can not only be affected artificially, but became naturally affected by the disease during an epidemic.

WOUNDS OF THE URETER IN CHILDBIRTH.

THE researches and experiences of Mr. Henry Morris, Dr. Howard Kelly, Dr. Fenger, and other contemporary writers have greatly advanced the surgery of the ureter, but an injury to that duct, not rare in the course of an abdomino-pelvic operation, is always a very serious complication. In childbirth it is much less frequent; still it is not unknown, and the after-consequences are distressing and ultimately dangerous, for urinary fistula with incontinence of urine is nearly always followed in these cases by destructive suppuration of the kidney. An interesting discussion by leading French authorities recently followed the reading by M. Pozzi of a report of an instance of the complication in question.¹ A woman, aged 35, consulted him because urine had come away through the vagina for nine months, beginning after a lingering labour. The cervix had been rigid, the membranes ruptured prematurely, and complete uterine inertia set in. On the fifth day the patient's doctor introduced the forceps after using Tarnier's dilator, but the cervix retracted as the blades of the forceps were being applied and manual dilatation proved a failure. Then some incisions were made in the cervix. Within a few days urine was observed escaping from the vagina, and the complication was ascribed to vesico-vaginal fistula resulting from an extension, during the extraction of the fetus, of one of the incisions made in the cervix. The patient was kept under observation, and it was noted that occasionally the urine ceased to escape from the vagina and that then she complained of sharp pains running from the right hypochondrium to the iliac fossa, accompanied occasionally by fever. M. Pozzi found wide laceration of both commissures of the cervix, especially on the right where the tear extended into a cicatrix occupying the corresponding vaginal fornix. No fistula, however, could be detected in the vagina, and nothing escaped from the uterus when fluids were injected into the bladder, yet the vagina was constantly moistened by urine. The right kidney was tender on palpation. Luys introduced the cystoscope and detected partial, not complete, obstruction of the right ureter a centimetre above its vesical orifice. As the left kidney and its duct were proved to be quite sound, Pozzi removed the right kidney. That organ was found to be the seat of hydro-pyonephrosis and its secreting tissue was almost destroyed. Four months later the patient reported herself as in excellent health and free from all urinary complications. Obstetricians, remarked Pozzi, believed that ureteral fistulae after childbirth were usually the result of

gangrene of the ureter by compression, especially in lingering labours, rarely to damage by instruments. The attendant at this labour, on the other hand, believed that a laceration beginning from one of the incisions which he had made, had really extended into the ureter. Pinard, in discussing the case, expressed doubt as to whether a laceration of the kind reported could involve the ureter; it would more probably extend upwards into the uterus. He considered forced dilatation and incisions unjustifiable. Under the circumstances, in this case the uterus should have been opened from above. Champetier de Ribes related an instance of uretero-vaginal fistula after basiotripsy. On the seventh day, probably after the separation of a slough, urine began to escape from the vagina; the fistula was closed by operation. Hartmann agreed with Pozzi that the kidney should be removed, as transplantation of the ureter above the stricture did not always bring about restoration of the functions of the kidney. Routier admitted that, in two cases in which he had transplanted the ureter, he found afterwards that that duct closed again, and the kidney underwent atrophy. In two cases of uretero-vaginal fistula spontaneous cure occurred, but in both the catheter proved that the ureter on the side on which the fistula had developed was strictured. Schwartz, who had removed a suppurating kidney two years after a uretero-vaginal fistula had developed as the result of damage during the extirpation of a big fibroid, said that the patient was doing very well seven years after the nephrectomy. Doléris, concluding the discussion, agreed with Pozzi that lateral incisions made in the cervix with scissors or scalpels might involve damage to the ureter. The duct was safe only when Dührssen's systematic incisions were made, as then it retreated before the knife.

PROFESSOR RAMON Y CAJAL, of Madrid, the famous anatomist and one of the winners of the Nobel Prize, has been created a Senator of Spain.

MR. SINCLAIR WHITE, Surgeon to the Royal Infirmary Sheffield, has been elected a corresponding member of the Surgical Society of Paris.

THE Hunterian oration before the Royal College of Surgeons of England will be delivered by the President, Mr. Henry Morris, on Monday, February 15th, at 4 p.m. Fellows and Members desiring to be present must apply to the Secretary for cards.

THE International Opium Commission was opened at Shanghai on February 1st by the Viceroy, who had a special Imperial mandate for the purpose. Subsequently the Commission unanimously elected Bishop Brent President, and Mr. Carey, Commissioner of Customs, and M. Gieter, interpreter to the French Consulate, secretaries. It was resolved that the official language should be English, the secretaries undertaking to make summaries of speeches delivered in other languages.

At a meeting of the Clinical Section of the Royal Society of Medicine on Friday next Mr. Butlin will, at 8.30 p.m., exhibit his collection of drawings of early carcinomas of the tongue and of conditions which may be mistaken for it, and will speak of the results of operations which have been practised in the cases exhibited. Microscopic sections of the cases will be on view. Messrs. Arthur Barker, W. C. Spencer, and G. L. Cheate will take part in the discussion of the subject.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

LIVERPOOL.

THE ROYAL INFIRMARY.

At the annual meeting of the Royal Infirmary allusion was made to several changes in the staff which have taken place during the past year. These were the death of Mr. E. R. Bickersteth, senior consulting surgeon, the resignation of Mr. George G. Hamilton and the appointment of Mr. W. Thelwall Thomas as surgeon in his place, and the election of Mr. F. A. G. Jeans as assistant surgeon. Dr. R. J. M. Buchanan, having been seven years assistant physician, has, according to the laws of the institution, become entitled to be styled "physician to out-patients." The financial state of the institution gives ground to some anxiety. The yearly expenses continue to increase, but the income does not increase in the same proportion. The cost of the x-ray department alone had been £500 during the year. When the present building was opened eighteen years ago a maintenance fund of £28,000 was liberally subscribed, and was expected to last for ten years. As a matter of fact, by judicious management and economy it is not yet all expended, and there is still one year's contribution remaining to be transferred to the general account. An urgent appeal is made for a fresh guarantee fund of £25,000 to enable the work to go on in the future with the same success as in the past. Apart from ordinary routine the most important step the committee has taken during the year has been the definite adoption of plans for a new out-patient department. Towards the cost of this, £10,000 has been given by the family of the late Mr. E. R. Bickersteth in memory of the deceased eminent surgeon, and this sum has been supplemented by another substantial and several smaller sums. It is intended to make an appeal to the citizens to assist in its maintenance. It is expected that the foundation stone will be laid in the course of the next few months, and that the work will be prosecuted without any unnecessary delay.

THE MEDICAL INSTITUTION.

At the annual meeting of the Medical Institution, on the recommendation of the council, an addition to the laws was passed by which practitioners of homeopathy who are ineligible as members of the institution shall also be ineligible as visitors. The membership of the society has largely increased of recent years, and the extension and decoration of the buildings has been greatly appreciated. Through the liberality of the president, Mr. T. H. Bickersteth, a convenient room has been comfortably fitted up for private study and research in the library.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

Sir Alfred Jones, chairman of the Liverpool School of Tropical Medicine, recently entertained a number of pupils of the school and friends of the movement at dinner. He delivered an address in which he recalled the fact that the Liverpool school came into being in 1898, and was formally opened on April 21st, 1899, by that greatest of scientists, their much-loved friend and counselor, Lord Lister. The university lent its indispensable aid, as did the Royal Southern Hospital. In the short space of ten years the school had spent no less than some £75,000 on the study of tropical medicine. With this term the school had started on a new system of instruction; three weeks had been added to the ten weeks' period of study, and the university had decided to give its diploma in tropical medicine only to students who had undergone this course of thirteen weeks. Owing to the lengthened term it would not be possible to give more than two such courses every year, and the courses had therefore been fixed to begin on January 6th and September 15th. The corresponding examinations for the diploma would be held about April 5th and December 13th respectively. In addition to these two full courses there would be a short course lasting only one month, for practical instruction in tropical pathology and medical entomology, to be given from June 1st to 29th each year. It was hoped that this would be of

the greatest utility to medical men returning on short leave to England, as it would enable them to acquire the practical technique of microscopic and similar work, which had been much desired by many of them. After the four weeks' short course, a class examination would be held, and a certificate would be issued for the first four weeks of the full Lent and autumn courses. The career of the school had been a brilliant one; it had numbered amongst its investigators no less than thirty intensely keen young medical men, drawn from the British Isles, the Colonies, and foreign countries. Most of these investigators had taken part in twenty-one expeditions to tropical countries—some had lost their lives in the enterprise, but all had added materially to their knowledge of tropical diseases, and had been the means of bringing about a revolution in the health conditions in the tropics. They had, in addition, trained 255 medical men and others to fit them to carry out effectively their work in our tropical possessions. Not only had the study of tropical diseases conferred an immense benefit upon the science of medicine, but it had given new and undreamt-of advantages to commerce, civilization, and to administration in tropical countries. They could point to Ismailia in Egypt, Klang, Port Swettenham, Hong Kong, Marathon, and many other places where malaria, if not eradicated, was fast disappearing. Only recently Dr. Johnston, who had thirty years' experience in Jamaica, visited the Liverpool school to bear testimony to the value of their teaching in the prevention of malaria. In Dr. Johnston's own experience it had reduced the mortality amongst the native soldiers of the West Indian regiments serving on the West Coast of Africa some 75 per cent. The preventive measures were not only of use to white trading officials and officers, but also of immense advantage to the natives themselves. Similar eloquent testimony had been recently furnished by Sir Henry Blake and by many other administrators, medical men, and travellers returning from the tropics. Similarly Rio, Santos, New Orleans, Havana, and the Philippines had been rendered as safe and as secure as any modern well-governed province or city in Europe. The construction of the Panama Canal was no longer a health problem; the previously insurmountable barrier of disease had been removed. The work had increased by leaps and bounds, and unless more financial support was forthcoming their work would have to be very seriously curtailed.

MANCHESTER AND DISTRICT.

WOMEN DOCTORS AND THE ROYAL INFIRMARY.

A CONSIDERABLE amount of excitement has been caused among women doctors and medical students in Manchester by a letter from Judge Parry in the *Manchester Guardian* on the subject of the appointment of women resident medical officers at the new infirmary. No one can ever charge Judge Parry with wrapping up his convictions on any subject, and he leaves us in no doubt as to his opinions on this point. He admits that something might be said for appointing a woman doctor for the women's and children's wards, but considers the suggestion to appoint a woman as a general resident medical officer to be "indefensible." He continues:

In my view we have no right to impose on the sick poor a class of medical treatment that we should consider unsuitable or undesirable for ourselves. The tradition of the infirmary has always been to give sick poor the very best medical attention and comfort that can be obtained, and the best measure of that is to be found in what rich people, who are free to choose for themselves, do actually choose. For the infirmary to appoint a general resident woman doctor would be to exploit the infirmary as a charity in the interest of a particular class of medical education. I feel sure that many subscribers would resent that course.

The Chairman of the Infirmary Board has also thought it necessary to correct a wrong interpretation which the press and the women's deputation put on his previous remarks. It had been assumed that the board had really decided in favour of the appointment of women, and that the only obstacle that prevented immediate action was the want of accommodation. He thought he had stated with sufficient clearness that the appointment of women as resident medical officers had not been fully considered by the board, and that no conclusion had been come to on

account of the difficulty of providing accommodation. He adds that to assume that the accommodation required would only be one small bedroom and one sitting-room is to take a very superficial view of the matter. In reality the change might involve additional buildings and necessitate rearrangement of and additions to the domestic staff and the reorganization of the work of the infirmary. The board could not at present undertake to deal with such a far-reaching question. Further, he says that though the educational facilities which the hospital affords are of great importance, the primary object of the charity is the welfare of the patients, and anything likely to interrupt the general work of the hospital is to be avoided.

THE PUBLIC HEALTH LABORATORY.

The public health laboratory associated with the Manchester University is at present conducted in York Place, some distance away from the university. Its work is concerned not only with the training of medical students under Professor Delépine, but also is associated with the wider interests of the public. As director of the laboratory, Professor Delépine has during the past year been engaged on an exhaustive report on the prevention of tuberculosis from tuberculous milk. As far back as 1892 he drew attention to the dangers of an infected milk supply, and the report, which is being compiled at the request of the Local Government Board, will contain something like a quarter of a million data that have been examined and correlated. Investigations, too, have been made at the instance of the Manchester corporation as to the effect on health of air impregnated with sewer gas. The value of the various types of mechanical filters for the treatment of drinking water has also been investigated. A special inquiry is being made by Drs. Lea and Sidebotham as to the reliability of bacteriological diagnosis in the detection of sources of puerperal fever.

Of late years there has been a constant and increasing demand for special and routine investigations which can only be undertaken at a properly equipped laboratory, and this, together with the regular teaching requirements, have made the present accommodation far too small. There are now fifty-five students using the laboratory, and the success of the teaching is shown by the positions which past students have obtained, there being now a considerable number of medical officers of health in various parts of the country who have received their training in this laboratory. At present the building is in debt to the extent of over £4,000, and the constant demand for further connected researches can hardly be met without a substantial endowment. At present the fees obtained for the work of the staff are the chief sources of income, and are not sufficient to support it adequately.

WEST YORKSHIRE.

OPEN-AIR SCHOOL TREATMENT IN BRADFORD.

The open-air school established experimentally last year at Thackley by the Bradford Education Committee is the subject of an interesting report by Dr. Crowley, the Medical Superintendent. Physically, all the forty children were unsatisfactory in one way or another. The curriculum included ordinary school work, with outdoor lessons; nature study and intervals for play and rest; three meals a day were given. The rest consisted of an hour's sleep in deck chairs, and both shower and slipper baths were provided. Physical exercises formed an important part of the curriculum. The results of the school were shown in an improvement in the general appearance and carriage of the children, increased weight and chest measurement, and improved condition of the blood, as shown by the amount of haemoglobin present. The cost of maintaining a school of this description is, of course, greater than under ordinary conditions, but Dr. Crowley looks on this class of school as part of the great movement in preventive medicine, and must necessarily lead to the greater efficiency of the individual, thus returning the capital used in an indirect manner. The report is convincing as to the advantages to these poor little weaklings; but it appears that something further will soon have to be done in this direction. Why are these weaklings

here at all? If the municipality is compelled to perpetuate an undesirable factor which it has not the power at present to prevent, is it not necessary that some action should be taken in the future in this direction? A report on the physical condition of the parents of these children would be of assistance, and perhaps Dr. Crowley will be able to undertake such an investigation. Where it becomes the duty of the municipality to see that delicate infants are reared in the most hygienic manner possible, should it not also have some say in the antenatal or anteconception condition of its future protégés?

BIRMINGHAM.

EPIDEMIC OF MEASLES.

The report of the medical officer of health (Dr. Robertson) for last week indicates that a somewhat serious epidemic of measles has broken out in various parts of the city. Measles has assumed just now a greater degree of prevalence than for some years past. Last week there were 20 deaths from measles, as compared with 15 in the preceding week, and 8 during the week ending January 9th. Twenty deaths is an exceptionally large number, and there have not been so many for two years. Most of the deaths were due to the fact that the parents do not take sufficient care of their children when they are afflicted with this disease.

WALES.

WEST WALES SANATORIUM.

At the annual meeting at Carmarthen of the governors of the West Wales Sanatorium, opened last summer at Alltymynydd, the Chairman deplored the absence, through indisposition, of Mrs. Davies-Evans, wife of the Lord-Lieutenant of Cardiganshire, who had not only taken the leading part in the sanatorium movement from its inception, but had been the prime mover of the presentations which they would shortly make to gentlemen who had held office in connexion with the executive. He particularly referred to Dr. Douglas Reid of Tenby, the first honorary secretary, Mr. P. J. Wheldon (Carmarthen), the treasurer, and Dr. Bowen Jones, another honorary secretary. To Dr. Reid, who was the pioneer of the movement, he handed a replica of the Cromwellian cup; a silver salver was presented to Mr. Wheldon, and a silver inkstand to Dr. Bowen Jones. Dr. Reid, in reply, recalled the seven years' work which culminated in the erection of the sanatorium. He commented on the practical solicitude of the late Lady Drummond, who had given a large sum of money, without which the sanatorium could not have been built. As to the clerical work, he said he had 3,500 letters in his possession; all of them had been answered, some of them twice and thrice. Altogether about 10,000 letters had passed through his hands. Mr. Wheldon showed how ignorance and prejudice in regard to the suppression of tuberculosis had been overcome, and Dr. Bowen Jones paid a high compliment to Mr. Wheldon, who, he said, had done a great deal of secretarial work for him. Mr. Parry Edwards was also presented with a silver inkstand, in acknowledgement of aid rendered to Mr. Wheldon in the financial department. "Profound gratitude and satisfaction" was expressed by the governors to Princess Christian for her gracious message intimating her desire to become the patroness of the West Wales Sanatorium, and with acclamation her name was so enrolled. Earl Cawdor, was elected president, and Mr. D. Davies, M.P., Llandinam, Sir James Drummond and Colonel Davies-Evans were appointed vice-presidents. Mr. Wheldon was re-elected treasurer, and Captain Harries, of Bryntowy, consented to become the honorary secretary, the consideration of the appointment of a paid secretary being postponed. The treasurer, in his annual report, which was adopted, stated that the receipts for the building fund came to £8,367 5s. 2d.; £1,000, lent by Sir James Drummond, had been repaid; and about £415 was due to the contractor and building side of the account. An adverse balance on the building side of the account. The furnishing account, including £500 from Mr. David Davies, M.P., came to between £800 and £900, and there

was a deficit of £27. The maintenance account, which had been in existence for four or five years, contained a separate account made by H.R.H. Princess Christian. On this there was a balance of £32 12s. 9d. The auditor had declared that £1,672 3s. 5d. had been collected for the maintenance fund for 1908-9. Colonel Davies-Evans observed that there was £331 0s. 3d. in hand on account of the memorial account. The honorary secretary (Dr. Bowen Jones), in his annual report, expressed warm thanks to Mr. D. Davies, M.P., for his generous contribution of £500 to the furnishing of the institution, and to Llanelly subscribers for a contribution of £294 9s. to the same fund, in addition to the gift of the turret clock.

The Medical Superintendent (Dr. Basil Adams) submitted the first annual report, and stated that since the formal opening of the sanatorium, by Princess Christian on July 20th, 1908, additions had been made to the staff, bringing the total to ten. On August 25th the first patients—four men and one woman—entered the sanatorium, and by October 3rd all the male beds (12) and half the female beds (5) were occupied. On December 31st 20 patients were undergoing treatment. Up to date 30 had been admitted (12 from Carmarthenshire, 11 from Pembroke-shire, and 7 from Cardiganshire) and 10 discharged. Of the discharged, 2 were fit for work, to which they returned and were now working; 2 were fit, and were looking for suitable work; 4 were continuing treatment (one in another sanatorium); and 2 proved to be unsuitable cases. With one or two exceptions, the cases admitted were not of the type that had been expected, as they did not come within the category of early cases. The most suitable had to be picked out of a large number of applicants, over 30 unsuitable cases having been examined and refused. It was hoped that all interested in the sanatorium's welfare would not advise cases of several years' standing to apply for admission, or that class which sought treatment as "a last resort" or "their only hope." That would only lead to much trouble for the authorities and disappointment for the would-be patients. Apart from the 2 unsuitable cases, all the patients had made satisfactory progress. The Chairman spoke in commendatory terms of the splendid work of the medical superintendent, Mr. Wheldon hoped that some generous benefactor would provide a pony and trap and a microscope.

Ireland.

[FROM OUR SPECIAL CORRESPONDENT.]

ALCOHOLISM AND THE POOR LAW.

DR. FULTON, one of the visiting medical officers to the Belfast Poor-law Infirmary, recently made a report as to the number of alcoholic cases admitted to the infirmary, the expense necessitated, and the encouragement thus given to the manufacture of that class of pauper; many of the cases were said to be well able to pay. The statistics have been sharply criticized, and at a meeting of the board on January 26th Dr. Fulton made an explanatory report which considerably modified the impression given by his former one. There were 78 cases of delirium tremens out of the 490 alcoholic cases mentioned during 1908; the sum £3 12s. formerly mentioned as the cost per week was not the actual cost, but given as a guide to guardians as to what they should charge if they had power to exceed the 6s. 5d. Many of the cases required hospital treatment, which they could not get elsewhere, and their lives had been saved by admission to the infirmary.

THE VICE-CHANCELLORSHIP OF THE NATIONAL UNIVERSITY.

At a meeting of the Senate held this week, the election of a vice-chancellor was considered. It is announced that two candidates were proposed—Sir Christopher Nixon, Bart., and Dr. Sigerson. The former is Vice-Chancellor of the Royal University, and is very well known. Dr. Sigerson is devoted to the cultivation of Celtic literature. He is Professor of Biology in the Catholic University

Medical School, and Fellow in the Royal University. The Senate was unable to come to a decision, and the election was postponed to a future day.

IRISH IN THE NATIONAL UNIVERSITY.

The Gaelic Leaguers, who are intent upon having Irish made compulsory in the new National University, have not received the bishops' views with any cordiality. The so-called West Briton character of some of the prelates is openly discussed and not in flattering words. The leaguers point out that the bishops admit that the matter is one for fair discussion, and they make liberal interpretation of the words. The Dublin Corporation on Monday last had the following motion under consideration:

That the present being a grave epoch in the native language movement, fraught with momentous consequences to national education, in its primary, secondary, and university stages, and to the University of Ireland, in the position it should occupy, as a reviving centre of national thought, in the coming restoration of the Irish language, the Corporation of Dublin therefore resolves: (1) That the time has arrived for the expression of the will of the Irish people upon this supreme racial question by a demonstration of national magnitude in the City of Dublin. (2) That in order that such demonstration should have national dignity all creeds and classes should participate. (3) That to accomplish these objects, a conference, representative of all phases of opinion throughout the country, and of public bodies, should, in the opinion of this corporation, be immediately convened by the Gaelic League.

Dr. McWalter (Alderman) proposed as an amendment:

That the corporation has absolute confidence that the (Catholic) Archbishop of Dublin, as Chancellor of the National University, will take all necessary steps for the safeguarding of the Irish language in that university.

But the temper of the members is indicated by the rejection of the amendment, which only received 4 votes against 38 for the motion.

What is called the Students' United Association sent a deputation to a meeting of the United Trades Council on Monday night on the same subject. It was stated that they wanted to put some of the spirit of the students of other countries into those of Ireland. The council was asked to co-operate in a torchlight procession after a meeting in the Mansion House on Monday night next. And the request was agreed to.

The movement, noisy but not large, spreads through the country, and the Senate of the university is rather to be pitted in the face of this crusade. It is known that the members are much divided in their views, but the day must come when they will have to answer the question, "Under which king?" A sedate university finds itself suddenly in the midst of a great political storm, and it will need considerable astuteness to steer it through its troubles. But the feeling grows that the attacking forces are losing strength, and that in the end the bishops will be victorious.

RESEARCH DEFENCE SOCIETY.

A branch of the Research Defence Society has, as was stated in the JOURNAL of January 30th, been founded in Dublin. The inaugural meeting was held in the Lecture Theatre of the Royal Dublin Society on January 27th. Sir John G. Nutting, Bart., D.L., who took the chair in the unavoidable absence of the president of the society, the Earl of Cromer, said the fact that before the branch was actually formed over two hundred persons of every class and profession in Dublin, in addition to a large number of medical men, had intimated their intention of joining, showed what a widespread feeling existed in Ireland in reference to scientific research. People were anti-vivisectionists because they were either uninformed or misinformed. The Very Rev. the Dean of St. Patrick's proposed the first resolution as follows:

That a Dublin branch of the Research Defence Society be, and is hereby, established.

He said it was humiliating that the advocates of science should be so hampered in their efforts, and so slandered as to their motives, that a society of that sort should be needed among those who benefited every day by their labours in the cause of humanity. He regarded the society exactly as he regarded the Society for the Prevention of

Cruelty to Children. The society had nothing at all to conceal, and it had every motive to court and provide the fullest inquiry. After giving instances of the great value to humanity of results obtained by experiments on animals, he said there were a few who would say that it was altogether wrong to experiment on animals, however painless the experiment might be. What lay behind that position was this: That the life and the happiness of the lower animals were to be weighed exactly in the same scales as the life and the happiness of mankind; that they had rights to equal treatment. Those who used that argument did not understand what human life meant, and were led away by false sentimentalism which prevented them from realizing the vast amount of suffering beyond their immediate ken. Count Plunkett, in seconding the motion, said that all they asked was that men of science might be allowed to strike at the roots of much human suffering, and, for this noble end, to experiment on the lower creation. No matter how they theorized, they could not put man on a level with the lower creation. The motion was passed, with two dissentients. Mr. Stephen Paget read a letter from Lord Cromer in which, after expressing his regret at being unable to attend the meeting, he went on to say that all interested in scientific research must attach the greatest importance to the action now being taken in Dublin, for which they were greatly indebted to the very able and energetic assistance afforded by Sir Henry Swanzy. Mr. Paget then spoke of the advances which the society had already made in England, and mentioned that, in addition, that example was being actively followed in America. Of the Antivivisection Society, he said, sensible people were sick unto death. They had flooded the country far and wide with literature which for badness was without a parallel. Its disseminators seemed to stand alone and unrivalled in the knowledge of how to be cruel. Dr. Horne, President of the Royal College of Physicians, moved:

That the sincere thanks of the Dublin Branch of the Research Defence Society are hereby given to the Right Hon. the Earl of Cromer, President of the Society, for his kind message conveyed through Mr. Stephen Paget.

After congratulating Mr. Paget on having secured Lord Cromer as the first president of the society, and referring to the work done in the laboratories of Ireland, he said it seemed a very curious fact that the State imposed the greatest difficulties possible upon men of high culture before permitting them to perform a single experiment. The precautions taken in this matter were wise enough in one sense, but when they looked around the country and saw what was going on in the rural parts, they found swineherds and cowherds and stud grooms performing the most serious operations on animals without any check or any inspection whatsoever. Mr. T. W. Russell, M.P., seconded the resolution. He said every one in public life was simply deluged at present with the literature of the antivivisectionists. Mr. Paget was quite right when he declared that they wholly misrepresented the position in the eyes of the public. The real issue was whether curative science was to be an observational science purely or an experimental science as well. The resolution was carried, there being only one dissentient. The Rev. Father Finlay, S.J., moved:

That the following do form the Executive Committee of the Dublin Branch of the Research Defence Society for the ensuing year, with power to appoint one or more honorary secretaries, who shall be or shall become members of the Committee: Dr. Coleman, C.M.G., Mrs. Francis Dixon, Dr. Frank Dunne, Dr. J. Magee Finny (President of the Royal Academy of Medicine), Mr. Jacob Geoghegan, Dr. Andrew Horne (President of the Royal College of Physicians), Mr. John Lentaigue (President of the Royal College of Surgeons), Dr. Lumsden, Professor Mettam, Miss Isabella Mulvany, LL.D., Professor Edmund J. McWeeney, Count Plunkett, Mr. George Prescott, Dr. Scharff, Mr. L. Edward Steele, Sir Henry R. Swanzy, and Professor W. H. Thompson.

He remarked that the type of mind which made its possessor shrink to think of the supposed fearsome cruelties to which he received his antitoxin, and knew him blissfully indifferent as to all that happened where his beef tea came from, furnished a pretty nut to crack for psychologists. Mr. Blood, K.C., seconded the resolution, which was carried without dissent.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

SCOTTISH POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

THE annual meeting of this association held in Glasgow on January 29th was well attended, and the occasion was taken to present to Dr. Matthew Martin, the treasurer, a very fine gold watch with a suitable inscription as some recognition of the valuable services he has rendered to the association since its formation. The annual report, which was adopted, stated that during the past year contra-advertising had not been so frequently required as in previous years. The secretary, Dr. W. L. Muir, 1, Seton Terrace, Glasgow, had been able to give full particulars to applicants for appointments in connexion with a number of parishes, and had given advice in many matters of difficulty, one of a somewhat novel kind being an incident in which the parish council professed to be unable to pay the medical officer's salary on account of want of money. Attention was called to the opposition of the Government to an amendment proposed by Mr. Wason and Mr. Cross in the House of Commons to add to the bill to amend the Local Government (Scotland) Act a clause to the effect that medical officers should not be dismissed from their appointment unless by or with the consent of the Local Government Board. Mr. Wason, however, had promised to reintroduce the Parochial Medical Officers (Scotland) Bill, which did not reach a second reading during last session. The financial report showed a satisfactory balance in hand.

THE LATE DR. ARGYLL ROBERTSON.

An Indian paper reports that by special request the body of the late Dr. Argyll Robertson was cremated on the banks of the river Gondli, the funeral service being read by the Rev. G. S. Stevenson. The ceremony was deeply impressive. According to ancient custom no Hindu Rajah can take part in a funeral procession, nor wear a black or white turban as a sign of mourning, nor do the ladies of a princely family go to the burning ghat, but all these ancient customs were broken by the Thakur Sahib and his family out of friendship for the distinguished surgeon. Not only so, but at the end of the funeral service the Thakur Sahib himself kindled the funeral pyre of his guru (teacher) and friend. Hindus and Mussulmans united in closing their shops as a mark of respect to the deceased, and in sending messages of condolence to Mrs. Robertson.

PROFESSOR CHIENE.

Owing to indisposition, Professor Chiene has been allowed three months' leave of absence by the University Court. His work in the chair of systematic surgery is being done by Mr. David Wallace, while his work in the Royal Infirmary wards has been undertaken by Mr. Alexis Thomson.

PROFESSOR CAIRD.

The Cap and Gown Club—the youngest of the social clubs of Edinburgh—had as its guest on Saturday evening, January 30th, Professor F. M. Caird, on his promotion to the Chair of Clinical Surgery in the University of Edinburgh. There was a large attendance.

COLINTON MAINS HOSPITAL, EDINBURGH.

The meeting of the Public Health Committee of Edinburgh Town Council on February 2nd had before it an extract from a report by Dr. Dittmar, the Medical Inspector of the Local Government Board in Scotland, who had visited the hospital on January 18th and 19th. The extract is in these terms:

So far as I could judge the administration is excellent. I would sum up my general impression of the hospital in all its parts as being by far the finest and best adapted for its purpose that I have ever seen. I do not think that Colinton Mains Hospital could be materially improved on in structure or general arrangement.

South Africa.

PERSONAL HYGIENE AND PUBLIC HEALTH.

DR. WILFRED WATKINS-PITCHFORD's presidential address to the Public Health Section of the South African Medical Congress was conceived in a thoroughly progressive spirit. He emphasized the point that municipal hygiene should not have only a negative side. It should aim not only at the prevention of disease, but at the provision of conditions in which good health can be attained and maintained by the whole community. "It should be as much a duty," he said, "to provide gardens and playgrounds as to insist on the proper ventilation of dwellings and the absence of overcrowding; the water should be not only free from dangerous contamination, but should be provided in quantities sufficient for the amplest cleanliness; food should not only be unadulterated, but should be intrinsically good; not only should vice and crime be suppressed, but a wholesome morality should be actively fostered." Perhaps it is owing to the spread of this same spirit that we now hear less of the term "preventive medicine" as a synonym for "public health administration."

In considering more particularly the problems of hygiene as applied to modern South Africa, Dr. Watkins-Pitchford enumerated as special features in the South African environment:

The mixed character of the population, the generally low standard of education, the comparatively undeveloped condition of agriculture and forestry, the high altitude of some of the more important parts of the country, the absence of large bodies of water, the heat of summer, the heaviness of the rain storms during certain seasons, and the dryness of the atmosphere and prevalence of hot winds and dust storms at other seasons.

Perhaps the most serious of these conditions is the absence of large bodies of water, combined with the character of the rainfall, which of course makes it particularly difficult to conserve. This involves an inadequate water supply in a climate where a particularly abundant one is almost an essential of health, and renders water carriage of sewage difficult or impossible. Dr. Watkins-Pitchford estimated that the minimum daily supply should be 150 gallons a head in South African communities, and for the provision of this he advocates the formation of lakes in the upland districts as the highest statesmanship. After dealing briefly with a number of matters in which public health administration in all countries is usually carried on in the same way, he made some very interesting comments on the personal habits of the people themselves, and especially the want of adaptability of the European colonists in such matters as dress and dwellings. It seems strange that in South Africa British conservatism should defeat common sense and the costumes suitable for the climate of London or Capetown, or that houses in a subtropical climate should be constructed of inferior materials and roofed with galvanized iron. Dr. Watkins-Pitchford suggests that the latter material should be heavily taxed, not only with a view to encouraging the home manufacture of roofing tiles, but also to ensure a healthier type of dwelling. He further advocates the construction of houses with basement stories, that is, with several rooms partly below the level of the ground, and with flat roofs. He points out that many houses on the shores of the Persian Gulf are so built; the basement rooms provide a cool refuge during dust-storms and hot winds, while at other times the family can enjoy an outdoor existence on the flat roof. Altogether Dr. Watkins-Pitchford is to be congratulated on an exceptionally interesting and suggestive address.

THE Local Government Board in England has issued a circular to local authorities calling attention to the Local Authorities (Admission of the Press to Meetings) Act, 1908, which gives to duly accredited representatives of newspapers and news agencies the right to attend the meeting of any local body which has the power to make a rate. The Act reserves to a majority of the authority at any meeting the power of temporarily excluding representatives if such exclusion be deemed desirable in the public interest.

Special Correspondence.

PARIS.

Académie de Médecine: Prophylaxis of Phlebitis and Embolism.—Election to Chairs in the Faculty of Medicine.—The Recent Disturbances in the Latin Quarter.—Society for the Study of Radiations.

AT a recent meeting of the Académie de Médecine Professor Chantemesse communicated the results of a research on the prevention of thrombosis and embolism by the modification of the patient's blood. It has long been known that under pathological conditions the coagulability of blood may be increased or diminished. Coagulation is due to a diastase—the fibrin ferment—whose action is helped by calcium salts and prevented by citrates, oxalates, and fluorides. Wright first proposed the application of these chemical methods in the human subject. The clinician found that other factors played an important part in intravascular coagulation, that is, the general and more particularly the local slowing down of the circulation, and the presence in the wall of the vein of microbes provoking coagulation. Professor Chantemesse laid stress on a third cause, holding that all conditions accompanied by a great destruction of blood slowly created in the organism a disposition to spontaneous defence, which to check the loss of blood increased its intravenous coagulability. Thus in typhoid fever or menorrhagia coagulability of the blood was spontaneously increased; and when contributory circumstances, such as slowing the circulation or surgical ligation, ensued, thrombus was formed or phlebitis occurred, and occasionally embolism—an accident particularly frequent in patients after operation for fibroma. Examination of the coagulability of the blood in typhoid fever showed that on the eve of hæmorrhages the coagulability fell greatly, and that it rose above normal when a phlebitis occurred. In a special form of spontaneous phlebitis which occurred in typhoid fever the patient had a violent rigor which recurred in a few hours or days, suggesting purulent infection, but there was no poly-nucleosis; a culture only showed the presence of the typhoid bacillus, and the condition was simply a parietal phlebitis, the rises of temperature being due to the migration of minute particles detached from the clot. If complete obliterating phlebitis with oedema ensued, the symptom usually ceased; a small dose of citric acid prevented the phlebitis spreading, but if the dose was too large, the clot dissolved too rapidly, and small particles carried into the general circulation gave rise to intermittent febrile attacks as in primitive parietal phlebitis. Professor Chantemesse had seen in a typhoid patient with repeated intestinal hæmorrhage the prolonged use of calcium chloride bring about phlebitis; citric acid caused the rapid recovery from the phlebitis, but the coagulability of the blood diminished so rapidly that hæmorrhages recurred. From these observations Professor Chantemesse concluded that the blood in women who were operated on for fibroma because they suffered from repeated hæmorrhage was more coagulable than normal, and that as the ligature favoured local stasis, voluminous thrombi were formed, and becoming detached caused sudden death. This theory was substantiated by the study of the coagulability of the blood in such cases, before and after operation, and before and after the administration of citric acid. In all cases of fibroma the coagulability of the blood was greater than normal before operation; after two or three days' treatment with citric acid the coagulability was again normal, and the patients recovered without any accident or embolus. The coagulability of the blood could be measured at the bedside. To prevent coagulation of normal blood *in vitro* an equal volume of solution of potassium oxalate of 1 in 800 was necessary. Several samples of blood were mixed with solutions of different strengths (300, 200, 100, 50, 25, 12.5, 6.25, 3.125, 1.5625), the mixture being kept in fine pipettes, as described by Wright. In a few hours it was easy to see if the coagulability was normal or above or below it. The chemical agents, when ingested, did not act until after two or three days, and must not be given for a longer period. The dose of calcium chloride must not exceed 4 to 6 grams daily, and of citric acid 12 to 18 or even 24 grams daily; they must

be given diluted in a large volume of water. Their use should be followed and regulated by repeated examinations of the coagulability of the patient's blood. Dr. Netter said that since the publication of Wright's results he had often used sodium citrate in phlegmasia.

The following nominations to chairs in the Faculty of Medicine have been confirmed by official decree:—M. Gilbert Ballet, Professor of History of Medicine and Surgery, has been appointed to the Clinical Chair of Mental Pathology and Diseases of the Brain, replacing Professor Joffroy, deceased; M. Pierre Delbet, Professor-Agrégé, has been appointed Professor of Clinical Surgery, replacing Professor le Dentu, resigned; M. Hartmann, Professor-Agrégé, has been appointed Professor of Operations and Instruments, replacing Professor Berger, deceased.

Following the rioting in the neighbourhood of the Faculty of Medicine, delegations of practitioners and students were received by the President of the Republic and by the Premier, M. Clemenceau. The incidents were discussed at a Cabinet Council, and as a result the examination which was held for the diploma of admissibility to the aggregation has been annulled. Moreover, the first and second year students have been permitted to continue their practical anatomy and lectures, and will be allowed to take their two registrations of January and March at the same time, but only on condition that no fresh disturbances occur before the month of March.

A new medical society has been founded, with the title "Société de biologie médicale de Paris," for the study of all radiations known in physics and their application to biological and medical science. The society will meet at 9 p.m. on the second Tuesday of each month at 12, Rue de Seine, in the rooms of the Surgical Society. The president of the society is Dr. Bécclère; vice-president, Dr. Guilleminot; general secretary, Dr. Harst; treasurer, Dr. Aubourg.

BERLIN.

Paying Patients in Municipal Hospitals.—Municipal Bacteriological Laboratories.—Decline in the Birth-rate.

THE Berlin municipal authorities are engaged in deliberations on a proposal to reserve special wards in the municipal hospitals for such patients as are able and prepared to pay full price for their accommodation and treatment. During the discussions the question has been raised whether Berlin citizens, other than the needy and indigent, are entitled to the benefits of hospital treatment on payment of the fixed sum. Curiously enough, no authoritative answer can be given. Some of the magistrates hold that the municipal hospitals were erected and destined solely for the care of the "legal poor," although at a later period the municipality made an arrangement with sick clubs and similar organizations to admit their members on payment of 2 m. 50 pf. (2s. 6d.) a day; all other Berlin citizens, they hold, should be rigidly excluded, save under circumstances in which non-admittance might endanger life, and they therefore conclude that it is illegal to take in well-to-do citizens as paying in-patients. Others hold the opposite view. Among the hospital rules and regulations there appears to be none that enjoins the exclusion of any class of citizen, and the large number of artisans, business men, teachers, and officials who form the staple of the paying in-patients would be indignant if they were accused of having entered the hospitals (to the expenses of which they, as ratepayers, contribute) illegally. At the same time, it is recognized that 2s. 6d. a day is far too low a charge for well-to-do patients, and it is suggested that it should be raised to a sum which would mean, at least, no loss to the hospital.

Three institutes for bacteriological examinations in cases of infectious disease, on lines very similar to the State institutes, have been started this year by the Berlin municipality. Their object is twofold: First, to undertake bacteriological examinations on the appearance of epidemic or infectious diseases at the request of the medical officials or of the police authorities; and, secondly, to carry out bacteriological examinations gratuitously (at the request of physicians or general practitioners) in cases in which infectious disease is suspected but cannot be confidently diagnosed without careful bacteriological

examination. The three institutes will be chiefly concerned with diphtheria, meningitis, typhoid fever, dysentery, and with the toxic effects of trichinosis, anthrax, glanders, and meat, fish, and sausage poisoning. Tuberculosis will still be left to the State institutes. To facilitate the sending of samples special vessels have been prepared, and are to be kept in stock at every chemist's.

The surplus of births over deaths in Germany—that is, the actual increase in population—which had amounted to 910,275 persons in 1906, fell to 882,625 persons in 1907, this decline being due almost in all districts to a decrease in the births. Nevertheless, in respect of the surplus of births Germany compares favourably with the other great States of Europe both as to the crude figures and as to their proportion to the population.

Correspondence.

THE ACCURACY OF THE MEDICAL REGISTER.

SIR,—A very searching inquiry is now being made as to the accuracy of all names and addresses on the *Medical Register* under the following Section (XIV) of the Medical Act, 1858:

XIV. It shall be the duty of the Registrars to keep their respective Registers correct in accordance with the provisions of this Act, and the Orders and Regulations of the General Council, and to erase the Names of all registered Persons who shall have died, and shall from Time to Time make the necessary Alterations in the Addresses or Qualifications of the Persons registered under this Act; and to enable the respective Registrars duly to fulfil the Duties imposed upon them it shall be lawful for the Registrar to write a Letter to any registered Person, addressed to him according to his address on the Register, to inquire whether he has ceased to practise, or has changed his Residence, and if no Answer shall be returned to such Letter within the Period of Six Months from the sending of the Letter it shall be lawful to erase the Name of such Person from the Register, provided always that the same may be restored by Direction of the General Council should they think fit to make an Order to that Effect.

On February 1st a circular of inquiry was posted to every registered practitioner, *excepting only* officers of the Navy, Army, and Indian Medical Services whose names appear in the Navy and Army Lists.

It is of vital importance to all registered practitioners who have not received an inquiry in course of post that they should immediately communicate with this office, as in the event of no communication being received from them it will be lawful to erase their names from the Register, according to the Act, and then very serious disabilities will be incurred.—I am, etc.,

H. V. ALLEN,
Registrar.

General Council of Medical Education and Registration
of the United Kingdom, 229, Oxford Street,
London, W., Feb. 2nd.

THE TREATMENT OF SCHOOL CHILDREN.

SIR,—In the excellent report of the Medico-Political Committee with regard to the above subject the children are divided into three classes:

1. Children whose parents can provide the requisite treatment at their own expense.
2. At the other extreme, children whose parents are in such circumstances that treatment under the existing Poor Law is carried out.

3. Children falling into neither of the foregoing groups. There is no doubt whatever that Class 3 will gradually absorb Classes 1 and 2. Class 2 will be diminished by the natural inclination to keep out of the hands of the Poor Law; and Class 1 will gradually diminish, because, if a man can get his children just as well looked after without payment as by paying, it is not in his nature to go on paying.

Apart from these considerations, look at the tendency of the age. It is one of gradual Socialistic progress, and that progress alone will soon result in there being no three classes, but only one class. This will mean that

all children between the school ages will be inspected and treated free of all charge to the parents.

Now, we as a body of general practitioners must look ahead and adapt ourselves to these changing times. The system of treatment of these children should be such a system that could be made to meet any demand upon it in the future and yet not injure the livelihood of the general practitioner. I suggest that until the time comes when the State will pay for the treatment of all children attending school we adopt the measures handed in by Dr. A. H. Williams at the Annual Representative Meeting in 1908:

The medical inspector reports a child as defective. The parent is to be notified that the defect is to be attended to before the child may return to school. Should the parents be unable to pay for treatment then the Education Department is to give a voucher for the payment of the fee on a fixed scale. The parent may then take his child to any practitioner whom he may select, and the practitioner will receive his fee from the Education Department.

There are, however, many practitioners who would want to refer special cases to specialists. If existing conditions are left as they are, these cases would go to the hospitals—the very thing we want to avoid. In the working of this important measure there should be no consideration of any charity whatever. I therefore further suggest that specialists should be appointed (include all of them if possible), who would deal with these cases; but no case should go to any specialist except by a note from a general practitioner, together with the voucher. These specialists could see these patients either at their own consulting rooms, or they could have a building erected for their own convenience, and they would be paid according to a fixed scale. Such, stated briefly, is my proposal. This measure will assuredly pass quickly to the stage of treatment I have mentioned, and I think we ought to begin our method of treatment as we intend to go on.

By adopting this plan we should do away with a good deal of hospital abuse; it would mean a more comfortable existence for many a practitioner; no abuse could come into the system; no practitioner would lose his own patients, and, moreover, it would work very simply.—I am, etc.,

Liverpool, Jan. 25th.

A. STANLEY PARKINSON.

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

SIR.—Dr. Morgan Finucane's criticisms in the *JOURNAL* of January 30th of my suggestions which were published under the above heading in the *JOURNAL* of January 9th call for some reply.

If Dr. Finucane's deductions had not been drawn from false premises, they would carry considerable weight, but he attributes to me suggestions I have never made, and then proceeds with strong adjective and sweeping condemnation to storm a position I have never occupied. I agree with nearly all Dr. Finucane says with regard to the existing Poor Law, but I have not advocated the treatment of the defective school children under the auspices of the Poor Law as it exists at the present moment. I have merely called attention to the fact that legislation is pending which will reform the Poor Law on the lines laid down by the Royal Commission, and it is this reorganized and reformed Poor Law, a Poor Law purged of all the evils to which Lord Lytton and Mrs. Barnett, and many others, have called attention, and which Dr. Finucane quotes with so much zest. I assure Dr. Finucane that I have no wish, and have never suggested, that the defective scholars under discussion should be sent to join the "rows and rows of fat, clean, well-shod, bored, and distless children" sitting in a barrack school.

Dr. Finucane cites the worst side of the Poor Law—an aspect of it already falling out of date; but surely, as a late guardian, Dr. Finucane should know that the modern tendency is against barrack schools and towards the scattered homes plan. I even instanced in my letter the scattered homes for ophthalmia under the Metropolitan Asylums Board. Dr. Finucane, however, ignores this, and, although he urges us to think Imperially, his own mind on this subject seems filled by thoughts of the "rows of sleek children" already mentioned. But all this is sentiment—and much of it false sentiment, in my opinion—for if a man is dependent upon public charity his position in the State is morally the same, no matter by

what name he be called or by what charitable organization he exists.

To come to the one practical point in Dr. Finucane's letter: He states that if the proposed work for the children were undertaken under the auspices of the Poor Law, "the necessity of greatly increasing the staff and equipment of the various infirmaries would entail such enormous expenditure as to make the scheme impracticable," and more costly than that of school clinics. Surely a certain staff and equipment will be required in any case, whatever system be adopted, and I fail to see that it would be more costly to add to and improve an existing service than to start a new one. Dr. Finucane does not tell us why he thinks the work would cost more under the Local Government Board than under the Board of Education.

All I urge is that the education authority should hold their hand until the Poor Law Commission's Report is published, and then strengthen the plea of those who see the necessity for a reform of the existing Poor Law—Dr. Finucane and myself among them—by deciding to confine themselves to education, and leaving the public health authority—the Local Government Board under the Poor Law—to treat the children with regard to matters medical.—I am, etc.,

London, S.W., Feb. 1st.

HARVEY HILLIARD.

ATOXYL AND SOAMIN AND THE TREATMENT OF SLEEPING SICKNESS AND SYPHILIS.

SIR.—In the *JOURNAL* of January 30th, 1909, p. 285, attention is drawn to the last quarterly report of the Progress of Segregation Camps and Medical Treatment of Sleeping Sickness in Uganda, by Captain A. C. H. Gray, R.A.M.C.

One of the most important of the somewhat diverse reports collected from the medical officers in charge of the different segregation camps is that by Dr. Van Someren, Medical Superintendent of the Chagwe Camp. As you state:

Dr. Van Someren reports adversely on the combined treatment by atoxyl and mercury, but gives a more favourable account of a new drug, "soamin" (sodium-amino-phenyl-arsinate; Burroughs, Wellcome, and Co.).

Now, this is very strange, because "soamin" and "atoxyl" are the same thing, both being sodium-amino-phenyl-arsinate. Soamin is the trade name for Messrs. Burroughs and Wellcome's product, and atoxyl that for the product first put on the market by the German firm (Lanolinfabrik, Martinikenfelde, Berlin). Any superior results obtained by Dr. Van Someren, therefore, were not due to his using a different drug, but to his using, in all probability, a pure commercial preparation of that drug. I have had personal experience in my own work of this preparation of Messrs. Burroughs and Wellcome, and can testify to the purity of the preparation and its efficiency in animals affected by trypanosomes.

This error has involved a large amount of labour and of unnecessary printing on the part of the Sleeping Sickness Bureau, and it seems to me well that public attention should be drawn to it, so that this spirited competition between atoxyl and soamin may come to an end.

The same mistake has been made by observers using soamin in syphilis and other diseases, but it is curious that it should have been allowed to pass by all the experts both at the camps in Uganda and on the Sleeping Sickness Bureau in London, and a cablegram to Uganda that soamin is a pure form of atoxyl is distinctly indicated.

The substance in question is the sodium salt of para-amino-phenyl-arsenic acid, and was first discovered by a French chemist, Béchamp, over fifty years ago, and a few years ago was introduced as a drug by a German firm under the trade name of "atoxyl." It had a brief reputation as a drug in certain skin affections which was rapidly destroyed by the strong toxic effects of certain impurities, which led to blindness in some cases of its continued use.

The use of the drug was revived by the discovery of Thomas and Breil that it had a marked destructive action upon trypanosomes, and they suggested that it should be used as a drug in sleeping sickness.

It had been so used in many cases long before Koch used it in Africa, and by several observers, the cases being those

of infected Europeans. Koch's share in the work consisted in applying it on a large scale in an expedition of which he then fortunately happened to be in command in Africa; but from extensive experiments on animals and a certain number of cases in man, the action of atoxyl was well characterized and known before any of Koch's work appeared.

It was known to the workers in Liverpool that in all cases life was enormously prolonged by the administration of atoxyl, and that in all cases the parasites could be driven out of the blood by its use, and very often that many successive attacks could be cut short. We also knew perfectly well that in a large percentage of cases recurrences took place, and that ultimately a fatal issue could not be avoided. Why otherwise should we have sought for better methods, or introduced the atoxyl-mercury treatment?

Nor is it any news to us that the combined treatment with atoxyl and mercury often fails. Our own published results show that we have failed in curing large animals with the combined treatment.¹ But our experiments also indicate that it is a better treatment than that by atoxyl alone, and these results have been confirmed by several independent observers, not only in experimental work, but in treatment of sleeping sickness in man. Further, they are confirmed, in my opinion, by the results of this same Sleeping Sickness Bureau's report, which virtually recommends the abandonment of the combined treatment. Any one who reads the report can see that in all the different camps the percentage of improvements is greater and the percentage of deaths much less in the case of the combined treatment than with the arsenical preparation alone.

It may be pointed out that we are not here dealing with counsels of perfection (we rarely are in medicine, especially in the department of treatment), but with what is the best treatment for a disease which is invariably fatal when untreated. Quinine is a specific for malaria, yet there are cases which do not get better and ultimately die in spite of it; mercury is a specific for syphilis, yet, unfortunately, recurrences take place even after mercury. Similarly, amido-phenyl-arsenic acid is a strong specific for trypanosomiasis, and the best we know at the present time, especially in combination with a mercurial treatment. An ever-growing volume of evidence shows that a similar treatment is most efficacious in syphilis, another protozoan disease.

Surely it is too soon to pronounce dogmatic opinions derived from a few months' work in these segregation camps. If the workers have been disappointed as a result of the high anticipations raised by Koch's statements, it only shows that they are not among those who discount such statements at their true value, and are not carried away by lurid reports in the lay press.

In conclusion, I would like to be allowed to do justice to the work of another French chemist, Fourné, who pointed out that atoxyl was identical with Béchamp's substance, as credit is often ascribed to Ehrlich for this discovery. Ehrlich and Berthelm's work consisted in showing the true constitution of the body, in that the arsenic atom is directly on the benzene ring. A similar result was obtained and published practically simultaneously by Moore, Nierenstein, and Todd.—I am, etc.,

Liverpool, Jan. 30th.

BENJAMIN MOORE.

TREATMENT OF RHEUMATIC AND RHEUMATOID ARTHRITIS BY RADIANT HEAT AND CATAPHORESIS.

SIR,—Referring to the interesting article on the treatment of rheumatic and rheumatoid arthritis by radiant heat and cataphoresis, I agree that much benefit is derived by the heat from the radiant lamp, but am not able completely to verify the conclusions. Dr. Bailey attributes the extra benefit obtained from the large American lamp to the ultra-violet rays. Is it not a fact that the glass of the lamp prevents the passage of the ultra-violet rays? Experimentally I have found that a thin smearing of vaseline is sufficient to resist them, and the skin itself is a barrier to their passage, except under special conditions. Any ultra-violet rays which may pass will be used up in the superficial layers of the skin, and therefore their

therapeutical value is very small indeed. There is no doubt that this lamp has greater beneficial influence than the incandescent lamps as used in the ordinary way.

With regard to the adoption of local ionization in the treatment of rheumatic conditions, I have had many successes, but the condition of several after a prolonged course of treatment has been most disheartening.

At the present time it is difficult to give a definite prognosis in any special case; though the symptoms in many instances are similar, the reaction obtained is often disappointing. It would be interesting to have the opinion and results of other workers in this branch on similar cases to those Dr. Bailey has recorded.—I am, etc.,

West Hartlepool, Jan. 14th.

H. E. GAMLEN.

SODIUM BICARBONATE IN THE TREATMENT OF ACUTE RHEUMATISM.

SIR,—In his remarks on the use of alkalis in practical medicine, published in the JOURNAL of January 30th, my friend Dr. Eustace Smith writes:

When the salicylate is prescribed in large doses for the treatment of chorea, the addition of double the quantity of the bicarbonate of soda has been recommended by Dr. D. B. Lees for the purpose of counteracting any depressing effect of the salt, especially the dyspnoea which sometimes follows excessive doses of the drug. The chief objection to this practice is, of course, the profound anaemia which such medication is liable to induce.

I hope that Dr. Eustace Smith will forgive me for saying that his "of course" is simply another illustration of the fact that symptoms caused by the disease which we call "acute rheumatism" are too frequently ascribed to the remedies employed in its treatment.

In his second Harveian Lecture Dr. Cheadle writes:

The effect of rheumatism in producing anaemia in adults is sufficiently well known, but in children this is still more remarkable; the extreme pallor and the haemic murmurs are often most notable. . . . Where the rheumatic state is actively developed, anaemia proceeds apace in children. The presence of the rheumatic poison appears to be inimical to the red corpuscles or their haemoglobin; it either promotes their disintegration or interferes with their production.

And he quotes Trousseau's statement that there is, perhaps, no acute disease which produces anaemia so rapidly as rheumatism. With regard to chorea, Dr. Cheadle says, in the same lecture:

I am convinced that rheumatism is the by far most common and potent factor.

In the report on the Pathology of Acute Rheumatism and Allied Conditions, by Dr. Ainley Walker and Mr. Ryffel, published in the JOURNAL for 1903 (ii, 659), this sentence occurs:

The micrococci have a haemolytic action upon red blood corpuscles greater and more rapid than that of any other streptococcus which we have yet examined—a fact of interest in relation to the very rapid and considerable anaemia of rheumatic fever.

In severe untreated cases of rheumatic fever with pericarditis the pallor is often intense, but I have never seen any marked increase in the anaemia in cases treated by large doses of bicarbonate and salicylate; in fact, the more effectively the rheumatism is treated, the less is the degree of anaemia, as of other rheumatic symptoms.—I am, etc.,

London, W., Feb. 1st.

DAVID B. LEES.

THE IMPORTANCE OF RESEARCH IN MENTAL DISEASE.

SIR,—In the issue of the BRITISH MEDICAL JOURNAL of January 23rd I have read with interest the discussion in the Westminster Division on the subject of Dr. Maudsley's generous offer to the London County Council of the endowment of a hospital for the treatment of acute mental illness. Now, Sir, I fear greatly that the realized importance of the treatment of mental disease will obscure the infinitely greater importance to the nation of research regarding mental diseases. This would be a national calamity. The most up-to-date treatment of acute mental illness can easily be arranged for in suitable hospitals attached to our asylums if these are properly staffed and equipped and arranged with small wards and extensive verandahs. No town hospital can ever compete with a country one in treatment in a case where the "verandah

¹ Moore, Nierenstein, and Todd: *Annals of Tropical Medicine*, vol. i, 1908, p. 265.

hospital" is the ideal, and graduated garden work the best means of establishing convalescence. Research work, on the other hand, must be the basis of all advance in specific treatment, and research work can best be carried on in town, as isolation is a terrible barrier to the research worker. It seems to me that a strong effort should be made so to place the new mental hospital that it will be in very close touch with a fully equipped teaching school. Even if elaborately fitted up research laboratories are established at the new mental hospital, no one director can possibly be a leader and adviser in the many different directions that research may take.

The ideal is incorporation with a university whose laboratories would be available for research students in every line; and though in this way a suitable site might cost much more, a great saving in cost would result from the consequent efficiency and saving in laboratory equipment.

No small hospital can hope to retain the services of leading men in bacteriology, histology, physiology, psychological physics, organic chemistry, etc., while close association with a university and its laboratories would secure these advantages and tend to gather a group of young and keen research workers around the new school.

I earnestly hope that this aspect of the case will be given full consideration. Could a new pavilion for acute mental diseases not be built for one of the large hospitals which already have medical schools attached to them and properly equipped laboratories? I would again insist that treatment of an efficient kind can comparatively easily be arranged for on up-to-date lines; but if this chance of securing an efficient mental disease research school is lost it may be a generation before another chance comes to this country.—I am, etc.,

W. A. PARKER.

Gartloch Hospital for Mental Diseases, Gartloch, N.B.,
Jan. 26th.

APPLICATION OF MENDELIAN RULES TO HUMAN INHERITANCE.

SIR,—I am sorry if I still misunderstand Dr. Drinkwater; but when he takes upon himself the responsibility of developing an entirely new theory of Mendelism he must not be surprised if his readers cannot at once appreciate a position the consequences of which are so extraordinarily sweeping. In Dr. Drinkwater's paper which I criticized he wrote of Nettleship's pedigree: "The disease-bearing branches contain 255 members, of whom 53 per cent. were night blind; so that here again is another example of Mendelism in the human subject." There was no hint that a new method of counting had been adopted, which had never occurred to any Mendelian before; we were merely informed that "here was another example of Mendelism in the human subject." Counted in the ordinary and accepted Mendelian fashion, there were 237 normals, 133 abnormals, in addition to 10 normals and 1 abnormal of doubtful determination as to sex, and not improbably doubtful as to night-blindness also; 133 is not 50 per cent. of 370, but differs so widely from it that the odds against night-blindness following the Mendelian rule are gigantic. In order to get the necessary 50 per cent., about 100 normals have to be removed, and thus Dr. Drinkwater achieves by removing all the offspring of night-blind individuals who have had only normal offspring. Presumably he also removes—for so he informed me he had done—the offspring of first or second marriages of abnormals, when there were no abnormal offspring of such marriages.

I ask first: How can such a theory possibly help the medical man? Our discussion is on the application of Mendelian rules to man. On Dr. Drinkwater's theory the medical man cannot predict, until all the offspring are born to an affected individual, whether he will, on the average, have 50 or 0 per cent. of affected offspring; and, further, it depends on the relative prepotency of the parents, for it may be, to quote Dr. Drinkwater, that "in the human subject one normal may be recessive, whilst another normal is dominant to the abnormal. If this does happen, it may be that these 'last abnormals' were recessive to the normals whom they married" (January 2nd, 1909). Let us suppose that the "last abnormal" is (BN); then mated with (NN), we shall have 50 per cent. of (BN) or of recessive

night-blind persons, who would somewhere have appeared again in the descent—owing to intermarriage—as night blind, and broken the continuity of the long normal lines. It would be of interest if Dr. Drinkwater would give the gametic formula which he supposes would cover the cases of his "last abnormals," whose lines give only normals.

But there are still more serious criticisms to be made of Dr. Drinkwater's new Mendelism. What becomes of the 50 per cent. reached by the old Mendelism, if we are to follow his method of counting? The observations which gave 50 per cent. before must now be discarded, or are we to say that the Drinkwater rule is only to be applied when we fail to reach the correct percentage. Further, every Mendelian anticipates some cases, in which a (DR) × (RR) will give no abnormal offspring, just as he anticipates some cases which give all abnormal offspring. If one offspring only be born, it will be normal in half the cases and abnormal in the other half. If two offspring only are born there ought to be 25 per cent. of cases in which both are abnormal and 25 per cent. of cases in which both are normal; if three offspring are born there will be equal (12.5) percentages of cases with all the offspring normal and with all abnormal.

Dr. Drinkwater completely destroys the whole point of the Mendelian theory by cutting out every case in which (DR) × (RR) gave one, two, three, etc., runs of (RR). It is absolutely the same as if a man tossing a penny in arbitrary series of 1 up to 12 removed those series in which there was a run of heads when he set about demonstrating that tossing gave 50 per cent. of heads and 50 per cent. of tails. No logical mind would accept such a demonstration of the equality of heads and tails. Actually Nettleship's data give 14 cases in which one offspring only was born to an abnormal, and in 6 of these that offspring was abnormal. Dr. Drinkwater cuts out the 8 remaining cases in which one normal offspring was born to an abnormal. There are 5 cases in which two offspring, both abnormal, were born to an abnormal, and 10 in which two offspring, both normal, were born to an abnormal; the latter go out, according to Dr. Drinkwater's rule. There are 4 cases in which three offspring, all abnormal, were born to an abnormal, and 6 cases in which three normals only were born to an abnormal, the latter again disappearing from Dr. Drinkwater's results. He, however, included many cases in which one, two or three or more normal offspring were born to an abnormal before the first abnormal offspring came. Must the abnormal, who died before he got beyond the second or third normal child, be supposed to have a different gametic constitution from those who survived and had at last an abnormal offspring?

There is, in fact—not to mince matters—hopeless confusion in such a method of treating Mendelism. The author of it can hardly have realized that to obtain his Mendelian ratio he has introduced the absurdity that no true (DR) can die until he has produced at least one abnormal child; for, if he does, his gametic formula is a mystery, and his offspring are to be excluded from a count of the descendants of the abnormal. Certainly Mendel deserves better treatment from those who profess to be his followers!—I am, etc.,

University College, London, Feb. 2nd.

KARL PEARSON.

THE PREVENTION OF RECURRENCE AFTER OPERATIONS FOR CANCER.

SIR,—The paper of Mr. Charles Ryall, on the Technique of Cancer Operations,¹ shows clearly the danger the surgeon runs in operating of sowing the seeds of an early recurrence, and the mass of facts he has quoted point, apparently, most clearly to some autoinoculation of the patient of so active a type that he compares it to a bacterial infection in its character. I have no wish to dispute this, but I would venture to point out that, like so many theories in connexion with cancer growth, it does not fully explain all the facts of the case; most likely it is not the whole story, but probably there is another factor—possibly that of traumatism and after-irritation of the wound—that has also something to do with it, and which would just as easily explain the facts as presented. For instance, in the effect of curettage of a malignant gland he mentions, the recurrence might also be due to the bruising and tearing

¹ BRITISH MEDICAL JOURNAL, October 3rd, 1908.

of the tissues, as well as the dissemination of cancer cells which conceivably take place. The facts that appear to me to be somewhat against this being the whole explanation are that these facts are now very well known to surgeons operating for cancer, and a surgeon will not, if he can help it, cut into the cancer tumour whilst operating, giving it a good wide margin; yet even then cases are seen of stitch recurrence, and it is difficult to imagine that wandering cancer cells are so numerous in the outlying tissues as readily to infect the wound like that; if they are present in such numbers, then it is very difficult to understand why operations are as successful as they are.

There may be an additional factor in the case, and may that not be the traumatism and irritation caused by the stitches? In many cases the effect of traumatism may be quite clearly traced in the origin of cancer, particularly about the breast. The evidence is indisputable. In the analysis of a number of cases published by Cecil Leaf it is mentioned that traumatism accounted for at least 35 per cent., and that the percentage was probably higher than that. This does not prove that traumatism *per se* is sufficient to cause cancer, but in a patient disposed to develop it it may be the exciting cause; and in a patient already suffering from cancer surely trauma might be expected to develop it. It would be interesting to learn whether cancer has been known to develop in patients suffering from it who have sustained an injury, particularly a wound, in some remote part of the body which has subsequently developed cancer. The extreme rarity of antioinfection in cancer of the lip and in the mouth—I have never seen a lower lip infect the upper—is remarkable, and, even when it does occur, might be accounted for in another way. I have seen cases in which cancer has developed around a suture left in for some time after an operation. Two well-marked cases I remember where a suture was overlooked, which showed recurrence nowhere else; and another case of excision of the tongue by the method of division of the lower jaw, where the silver suture left to unite the symphysis was the centre of the most active recurrence. On the theory of traumatism and subsequent irritation of the wound by a foreign body this is just what would be expected.

Why cancer should develop about the stitch holes, and not on the cut edges and other parts of the wound, when all have been equally liable to infection, is only understandable on the explanation that a clean-cut wound does not cause so much irritation and injury as a stitch which is dragged through the tissues, and left to irritate the susceptible parts for many days. It may be that in certain persons, especially when already the subject of cancer, certain cells otherwise normal may, if bruised or irritated, be capable of taking on malignant action.

Mr. Charles Ryall does not even mention the most valuable means we have at present for preventing recurrence after an operation, namely, the judicious use of the x rays. Possibly he has not had experience of this, for if he had I think he must have mentioned it. I have found that the x rays, especially if used at the time of an operation where practical, are of the very greatest value for preventing recurrence in the site of the wound, and even when it does occur, especially in stitch scars, it clears up in a beautiful and convincing manner by this treatment. I advocate, however, the use of the rays from the very first in all cases; and then all these things that Mr. Charles Ryall describes do not occur. When it can be done it is an immense advantage to give the fullest possible dose of x rays at the time of an operation to the open wound, because it is a chance for the most effective use of the rays that never occurs again, as x rays are more effective on a surface than at a depth, and possibly may act by destroying loose cancer cells scattered about the wound if such exist. I have had a few cases dating back as far as five years in which this was done in which there has never been any signs of recurrence, the cases are possibly too few and the time too short to convince the sceptical, but should be very suggestive to those surgeons who are anxious to do all that is possible to save the great risk of recurrence that is always present in these cases. I will venture to quote one solitary case, of no great value perhaps to those who require evidence by hundreds.

About two years ago a woman, aged 32, had an operation for cancer on her breast. It was only a partial operation in an early cancer. It was doubtless an inefficient operation, and

should not have been done; it recurred at once, and was operated on most thoroughly by another surgeon six weeks afterwards, who removed the entire breast and cleared out all the glands; still, it recurred almost immediately, and he operated again, taking away the greater part of the pectoral muscles, and it was passed on to me at once for x -ray treatment. This was about two years ago, and up to the present there has never been the slightest sign of recurrence.

The unbelieving surgeon will regard this only as an example of thorough and successful surgery, and will hold that the x rays had nothing to do with it; but I have had very few failures, and quite enough similar successful cases to convince any unprejudiced observer, and think it is a pity that the great value of the x rays for preventing recurrence is being so slowly recognized. I think the reason is that the successful use of the rays is not so easily attained as is imagined; it is not so simple and easy as the administration of doses of salts or quinine by any one who happens to have an x -ray outfit at his disposal; and it is surprising what inefficient individuals this work is sometimes left to. Sometimes the hospital hall porter, or the handy man about the place, or a nurse; but, after all, I think the most inefficient x -ray work is done by the surgeon himself who happens to possess an outfit. No man can serve two masters, and a first class surgeon is very seldom a practical scientist, and, unfortunately, often despises what he does not understand. I hope I shall not be misunderstood as implying that surgeons do not conscientiously do everything possible for their patients, for I know many that do advise the use of x rays after operations; but, on the other hand, there are many who never even think of suggesting it. I was speaking about it to one who has operated on a good many cases of breast cancer, and he assured me that he had no recurrence in fully 80 per cent. of his operations; to such a one as that the x rays could offer no advantage.—I am, etc.,

Melbourne, Nov. 23rd, 1908.

T. G. BECKETT.

WORK IN COMPRESSED AIR.

SIR,—In his address on the Physiology and Pathology of Work in Compressed Air, in the BRITISH MEDICAL JOURNAL of January 30th, Sir Thomas Oliver describes a series of experiments carried out by Dr. Parkin and himself thus:

We subjected frogs to extremely high pressure, and after a time suddenly decompressed some of them. The web of a frog's foot was drawn over the inside of the glass window of the compressed-air chamber, and by means of the microscope and electric light illumination we could watch the circulation of the blood in the frog's capillaries. During compression the circulation proceeded quite naturally, but after sudden decompression, while the circulation seemed to go on apparently unchanged, by degrees the rate of the blood flow diminished, and gradually ceased, preceded by a slight to-and-fro movement. All at once a bubble or two of air would appear in the capillaries, and these running together formed a large embolus inside the vessel, etc.

Sir Thomas Oliver does not give a word of acknowledgment that he owes this experiment to me. It is an experimental demonstration of which any man may be justly proud, especially when it is completed by recompression bringing about re-solution of the bubbles, and, as I observed once, recovery of the circulation. It is the most convincing demonstration of the fact that bubbles are the cause of caisson disease, a fact which Sir Thomas Oliver was very unwilling to acknowledge in a conversation with me some years ago at the London Hospital Medical College. This is the second time Sir Thomas Oliver has described this experiment as if it was his own. The first time was when he read a paper at the Society of Arts, a paper for which, I believe, he was awarded a gold medal. The second time he goes a step further and describes experiments which demonstrate that relatively high percentages of CO₂ have no effect in increasing the risks of compressed air, without any acknowledgement of the work of Dr. Greenwood and myself, work which proved the statements made by him on this very matter at the Society of Arts to be erroneous.

In the matter of the frog-web experiment, Dr. Parkin was introduced to me by a distinguished colleague, and I was asked to give him help and advice as to the performance of experiments on compressed air. Dr. Parkin, under my direction, had a chamber made like mine, and repeated my experiment, and acknowledged his indebtedness to me in the thesis he wrote on this subject.

I have yet to learn of any single new experimental fact which has been contributed to the pathology of caisson

disease by Sir Thomas Oliver. How little of the experimental work he has done is shown by the fact that he describes the experiments as done on pithed frogs. He mentions with approval the method of stage decompression, which recently has been introduced as the routine practice in the Admiralty, a method founded on certain theoretical assumptions of Dr. John Haldane, and experiments on goats carried out to prove these assumptions by Dr. Haldane, Dr. Boycott, and Mr. Damant. I take this opportunity of saying that Mr. Greenwood and I have repeated on pigs some of their fundamental experiments on goats, and with contrary results. Stage decompression has proved in our experiments less safe than uniform. We do not admit the justice of the theoretical postulates on which it is based. There are many factors still unknown in the causation of decompression bubbles, and one of these we have some evidence to show is the presence of food in the alimentary canal. The escape of the men in the burst caisson mentioned by Sir Thomas Oliver may have been due to this in part, and in greater part to absence of fatigue, as the caisson burst about the breakfast hour. The increased number of cases which occur with long and repeated shifts we believe is due not to fuller saturation of the body with nitrogen, as Drs. Haldane and Boycott suppose, but to fatigue of the heart brought about by prolonged work. The circulation is then too feeble to allow the escape of nitrogen during decompression. The men sit quiet and weary in the lock. They ought during decompression to breathe oxygen and work hard.—I am, etc.,

Loughton, Essex, Jan. 30th.

LEONARD HILL.

THE HOME TREATMENT OF SCARLET FEVER.

SIR,—The line of prophylaxis indicated by the pathology of scarlet fever is for clinical purposes the same as in a series of fatal diseases such as diphtheria, measles, and whooping-cough, and of less serious affections such as influenza, mumps, and others. It is admitted that in all of them the upper respiratory tract is the head quarters of infection; yet are we ever taught that the entire stress of our efforts at disinfection should be concentrated upon that region? I have consulted our best and most recent textbooks, but in most cases I have found no reference under the headings of prophylaxis and treatment to this all-important matter. Doubtless the indication is so obvious that it might be held to go without saying. But the practical result of that silence is that it commonly goes without doing, as is too well shown by the relapses of influenza and whooping-cough, and by the late contact cases of diphtheria and of scarlet fever.

External ablutions are indispensable, and fortunately they are practised. But Dr. Robert Milne is entitled to credit for the attention which he pays to a more dangerous surface; only, if I may say so, his method is too limited locally in its application. Whether we are dealing with scarlet fever, or with any of the other diseases I have mentioned, we should bear in mind that cleanliness is the simplest and the most efficient of our antiseptics, and that our patient's disease is unwashed until the entire upper mucous tract is systematically and frequently cleansed. Opinions may differ as to the merits of the simple and painless method which I have long advocated and practised in all these conditions, namely, frequent instillations of jassin oil through the nostrils, to spread above and behind to regions inaccessible to sprays, douches, and gargles, to be continued from the onset through the entire duration of the period of observation. If this is not good enough let us find some better method. But let us not allege the fact that we cannot destroy the microbes *in situ* as an excuse for continuing to neglect adequate efforts to sweep them clean away.—I am, etc.,

London, W., Jan. 31st.

WILLIAM EWART.

THE REMEDIAL USE OF ALCOHOL.

SIR,—The address delivered before the Border Counties Branch by Dr. Macdonald bristles with controversial points. I will take only one—the treatment of lobar pneumonia. As Dr. Macdonald truly observes, an ounce of practice is worth a pound of theory.

In my experience of fifteen years' practice in a purely working class district on a clay soil, I have seen from forty

to fifty cases of lobar pneumonia, many of the patients being alcoholic subjects, and have yet to write my first death certificate for that disease.

I rely on digitalis, strychnine, careful feeding, and *absolute rest*, but always refuse at that critical period, when the overburdened and dilated right heart has almost reached breaking point, to help my patient over the precipice by prescribing the so-called stimulant that must often by its paralysing effect on the cardiac nerves, take away his last chance of recovery.

In a recent severe case of double pneumonia in a lad of 18 the crisis was delayed, and my courage almost failed, especially as the relatives begged piteously to be allowed to give him brandy "before he died." I assured them that, desperate as the case appeared, if they kept to the non-alcoholic treatment the patient would recover. And he did. "Lobar pneumonia, cardiac failure"—so runs the usual certificate, and the cause of the cardiac failure in 99 cases out of 100 is—alcohol.

I send this note just to encourage young abstaining practitioners who are apt to be led astray by dogmatic statements as to the virtues of the old-fashioned alcoholic treatment of lobar pneumonia.—I am, etc.,

Stoke-on-Trent, Feb. 1st.

A. A. HILL.

ALPINE OR HOME CLIMATES FOR EARLY TUBERCULOSIS.

SIR,—I have read with much interest the address delivered at the Medical Graduates' College by Dr. William Ewart on the above subject, and from a long experience of Alpine climate I am enabled to confirm all that Dr. Ewart expresses regarding the value of mountain air as a remedial agent in the treatment of early phthisical cases. The importance of the question is immense, but I can only briefly refer to the extraordinary change of opinion which has taken place in some quarters as to the virtue of climate in the open-air treatment.

For reasons which I will mention in a moment the Swiss Alps have not proved as attractive to frail people of late years as formerly. The family with a son or daughter who looked rather delicate but otherwise attracted no particular attention is not now so often seen. The young person who cannot walk uphill without a strained breathlessness, or other inoffensive individuals with a slight cough, are scarcely met with. It must be remembered that these "invalids" bring with them many relatives and friends in their train. We might therefore suppose that they would be welcomed by the Swiss hotel proprietor, and that he would do as much for the comfort and convenience of delicate clients as in days past. Instead, you see announced in hotel advertisements and prospectuses the intimation that "consumptive cases are not received," "persons with tuberculosis not admitted," and at the same time stress is laid on the "air cure" being especially potent in neurasthenia, debility, convalescence, and overwork!

I think it is almost a popular creed that mountain climate is *par excellence* more suited to lung troubles than to most other conditions, but one of the reasons for all this confusion is the "scare of infection." The belief that tuberculosis is "caught" by coming in contact with a person suffering from the complaint has taken root in places. Some persons have been known to write to an hotel to be assured that no consumptives were admitted before they settled on taking rooms. One thing and another has led the hotel proprietor to intimate publicly that his house is barred to such cases, and the "cases" have taken him at his word and remain at home, or perhaps visit the South Coast resorts. Others have the well-equipped English sanatoriums open to them. It may be asked why, if in search of health, they do not enter the sanatoriums of Switzerland and obtain with disciplinary treatment the grand advantage of Alpine air and sunshine. A few do so, but English people will never be induced to patronize largely the foreign sanatorium. This remark, of course, does not apply to the Alexandra Sanatorium at Davos, as that establishment will be English in the true sense.

It has become the fashion within the last few years for a winter holiday to be taken in Switzerland by thousands of English, and although they arrive late—say about

December 15th to 20th—such a large influx compensates for the thin autumn season and the absence of the invalid class who arrive earlier and make a longer stay. Every hamlet and many summer hotels that can offer good skating and tobogganing in winter with convenient slopes in the vicinity for the Norwegian ski, advertises and opens its doors for the two months of mid-winter devoted to "snow sports." There is an atmosphere of heroism and hurry about these places which ill suits the easy-going valetudinarian. A reckless excitement for speed leads to all sorts of accidents, and in some cases loss of life; but the magnificent surroundings of dry, crisp snow, keen, frosty air, and a brilliant sun are found nowhere like it in the world, and can be enjoyed in quite a rational, health-giving manner, if one is disposed that way. That there has been some neglect of Alpine climate, from a medical point of view, within the last few years can be explained by the establishment in England of first-class sanatoriums for open-air treatment, with excellent management and appropriate dieting, which have proved a counter attraction; but there is a factor among the manifold advantages of a calm atmosphere, with dry, cold air in the winter climate at the snow levels which we cannot obtain elsewhere in any such intensity or profusion—namely, *sunlight*. We shall hear more of the sun bath as time goes on.—I am, etc.,

Montreux, Switzerland, Jan. 23rd.

TUCKER WISE.

THE CAUSATION OF INGROWING TOENAIL AND THE LOCATION OF GOUT.

SIR,—Will you kindly allow me a short space to thank Dr. Joy for his letter in support of my theory with regard to ingrowing toenail and the location of gout?

As he points out in the last paragraph, long-continued pressure can cause gouty manifestations, in his case by direct pressure, in mine by indirect pressure. In the second paragraph he points out that ingrowing toenail is quite common on the outer side of the big toe, where, of course, the hoof, however tight, cannot press.

With regard to Fig. 2, I might say that the owner of the original would smilingly protest against such an accusation as wearing pointed boots, he being a member of the well-known family of tramps.

One can easily understand Dr. Joy's delight in the dear old textbooks, especially if they are well bound, but perhaps I may be allowed to point out that although my dear old textbooks suggest that chilblains may be treated by painting with tincture of iodine, I prefer to treat them with calcium salts; also it is of interest to reflect that whilst my dear old surgery textbook suggests that callous ulcers of the leg may be treated by bandaging, red lotion or even amputation, I prefer to rely on the method I introduced, namely, by calcium iodide.

My innate modesty revolts at the idea of attempting to add anything to that unfathomable fund of knowledge that exists in Harley Street, with which sentiment I feel certain I have Dr. Joy's sympathy.—I am, etc.,

Swansea, Jan. 31st.

G. ARBOUR STEPHENS.

CONFERENCE ON THE MEDICAL PROFESSION AND FRIENDLY SOCIETIES.

SIR,—Is it not rather sad—to use no stronger term—to find the Charity Organization Society intervening in the affairs of a body of educated men, and is it not somewhat suggestive of a trade dispute?

If we *must* imitate the methods employed in trade, let us at least take the position of masters, not that of servants. In the commercial world, when it is desired to raise the price of some commodity, those who control the market do not confer with their customers, they agree amongst themselves, and the price is raised.

Has not there been quite enough parleying? By all means let there be a conference, but let it be amongst ourselves, and let it be held with the firm determination to have no half measures, but to finally settle the question.

It is possible for the medical profession to struggle on without the help of the friendly societies, but I fancy that the latter would not have quite so huge a capital if we severed our connexion with them. So long as we allow the friendly societies to fix the terms of remuneration,

etc.—that is, to occupy the position of masters—so long must we be content to occupy the position of servants.

Unfortunately it seems to be indisputable that amongst our number there are many who put a very low value upon their services, and whose code of ethics is still lower. It seems probable, as "M.D." says in his letter in the JOURNAL of January 16th, that "as long as the 'powers that be' are unable or unwilling to inflict adequate penalties which shall touch the pockets of delinquents, so long will the friendly societies prey on us." Cannot, then, some effort be made to induce the licensing bodies or the General Medical Council to make it unprofessional conduct to accept contract work under the present system?

Assuming that canvassing and advertising are deemed unprofessional because they savour of trade methods, is not it inconsistent that acts which no tradespeople would be guilty of are allowed to pass unchallenged? Would any sane shopkeeper entertain for a moment the suggestion that he should habitually sell goods at a price far below their value? And yet this is what we do when we undertake to supply medical and surgical attendance to farmers, builders, and tradespeople for 4s. a year. If it is unprofessional to act like a tradesman, is not it also unprofessional to act like an idiot? I am sorry that I can think of no less offensive word to describe our conduct.

Instead of being a matter affecting only a certain section, is not it one which concerns the honour of the whole profession? If so, then surely it is the manifest duty of those in authority to make it impossible for the friendly societies to be in a position to say, "If one doctor will not accept our terms there are plenty of others who will."—I am, etc.,

February 1st.

ANHIDROTIC.

THE ST. JOHN AMBULANCE ASSOCIATION AND THE MEDICAL PROFESSION.

SIR,—I have read with interest the letters of Dr. Jepson of Durham and "Another Lecturer" in your issues of January 16th and 23rd, and beg to assure them that the same grievance of which they complain—the irregular method of distribution of honours by the Order of St. John—also obtains in South Wales. I have been an ambulance lecturer continuously for over fifteen years, and have done other work for the St. John Ambulance Association, for which I admit I have received the lowest grade of "Decoration" which the Order of St. John gives. But there have been two or three flagrant instances in this district of men receiving distinctions after two years' connexion with ambulance work. In 1905 I examined a man for a first-aid certificate, who in 1907 was promoted over my head (I am also an officer in the brigade) to a position on the staff of the district. The only reason assigned for this promotion after two years' work was the fact that he had contributed a few pounds to his local corps. Again, in 1906, I examined for a first-aid certificate a man who in 1908 was made an Assistant Commissioner for his district. This distinction, after two years' work, was due to the fact that he has collected a good sum of money for his local centre. These were (two laymen, but I know a retired army doctor in the South of England, who was made a Knight of Grace after three years' service for the St. John Ambulance Association.

I have talked over these matters with a large number of doctors who give ambulance lectures, and who are officers in the brigade, and they are so thoroughly disgusted with this favouritism, that if another instance occurs they will sever their connexion with both the St. John Association and Brigade.—I am, etc.,

January 25th.

DISGUSTED.

THE REPORT OF THE PUBLIC HEALTH COMMITTEE.

SIR,—Will you allow one interested in this matter space for a few comments? First, I would like to endorse Dr. Bowley's letter in the JOURNAL. It is almost impossible for me and many others to attend meetings of the Divisions. It means my leaving home about 12 o'clock, and getting home again at 8 o'clock, a length of time I cannot afford to be away from my practice. To notice the reasons advanced for the employment of whole-time men:

1. The everyday duties of sanitary inspection and supervision are not habitually performed by whole-time men holding large districts, in spite of paragraphs 1, 3, and 6 of the instructions of the Local Government Board. I have

a local paper containing reports of several meetings of local authorities, when the annual reports were read. In each case, the report as to the sanitary condition of the district, and the work done to improve such conditions, was from the sanitary inspector, the medical officer of health merely dealing with the statistics, etc. A man I met recently told me that in case of an outbreak of infectious disease in the district in which he resides the medical officer of health asks him to see to it. In a village near here, a cesspool taking all the drainage of the village has been allowed to exist close to the public well, and it was not till a new squire came into the place and complained that the medical officer of health took any action, or, as far as I can find out, had any knowledge of the condition.

2. This suggestion I maintain is a most unjust one to make. Where is there any justice or fairness in condemning a set of men on a pure assumption? When or where has it been shown that the part-time men as a whole do not do their duty because of fear of their patients? Let this be proved before damning a whole class of men, many of whom have been doing good work under most discouraging circumstances for years. Were not almost all the pioneers in the sanitary service part-time men, and did they do no work for fear of their patients? If you are going to argue from inference, not from proved facts, is it not agreed that a man cannot be expected to do good work while his appointment rests at the pleasure of men with whom he may come into opposition in the course of his work? But work is done in spite of this risk, and therefore I say that it is grossly unfair to assume that a man will not do his duty because he may have to deal with his patients. After twenty years' work I can say that I have had much less trouble to get work done by those who were my patients than by those who were not. People are much more likely to listen to a man in whom they already place confidence than to one who comes only to find fault.

3. He is more likely to have the interests of his district at heart than one who is not dependent on its welfare.

4. The knowledge of his patients and their home life is often of the utmost value to the medical officer of health, and he gets to know things no outsider could ever discover.

5. This argument applies equally to any and every public appointment.

6. This public opinion is largely manufactured by the inspectors of the Local Government Board, for of course if they take any view, the general public accept that as being the view of experts. The Local Government Board inspectors like large districts (I was told by one of them) because they get more uniform treatment of the statistics and of course it is much easier for them to deal with one large district than twenty small ones. But I have never known it said by any one of them that part-time men, as a whole, are not doing their duty as well as the whole-time men. If a man is not doing his work, he can be removed by the Local Government Board not approving his reappointment, and should be.

As an addition to the propositions for the employment of part-time men, I would point out that it is necessary for the inhabitants of country places to have medical men resident in the district, and it is to the advantage of the people that they should be good men. We hear a good deal about a proposed State medical service, to include sanitary and Poor-law officers. Now, if this work is to be taken from the general practitioner, how is he to live? There are lots of places where, even with these appointments, it is only possible to make a bare living.

We also hear of a possible national medical service. I would ask my brother practitioners to pause and think before they talk so glibly of a State service. The State's idea of the value of medical services is shown by the salaries offered to well-qualified men after six or more years' study; and it would seem from these that £250 a year is looked upon as affluence.—I am, etc.,

February 1st.

A COUNTRY M.O.H.

THE MEDICAL PROFESSION AND UNPAID STATE WORK.

SIR.—The question which rises uppermost in the minds of the thinking element of the laity with regard to the medical profession is, How do they live? See how the

medical man is mercilessly sweated from the birth of a child of poor parents to the death of this individual. A midwife is probably engaged to attend the mother in her confinement. There arises some complication which places the patient's life in danger. A medical man is summoned, and has to neglect his own work in order to attend to this case. Fee most probably *nil*, or at the most he has to be contented with what he can get. A medical man attends a confinement. The Government asks the doctor to send a notification to the local authorities. Fee *nil*. Then let us follow this child a little further. He goes to school, and his parents for some reason or another keep him away for some time. This means the loss of a grant, so at once the school officer tells the parent that a medical certificate must be obtained. No fee is offered, but medical men are now refusing to sign these certificates without reward. Medical school inspectors are appointed to ascertain physical and mental defects which may be present in the children attending elementary schools. No provision is made for remedying defects discovered, but this duty is expected to be carried out by medical men without fee or reward. The child grows up and the State protects him in every way. He must not work more than a certain number of hours a day, and he must not work except at union wages. If (generally through his own fault) he becomes unemployed, then the rates must help him. Again the unfortunate medical man must put his hand into his pocket to help pay the rates. Then the man grows old and obtains an old-age pension. We are told that this is thanks to a Liberal Government; but I should rather say, Thanks to the middle class, which does not take so much recreation as the working man (so-called), and which is the financial butt of all Governments. Some of these pensioners cannot visit the post office, so at once a certificate to that effect is required; let the medical man sign it. Fee *nil*. Then the old man dies and requires a death certificate to be signed by a medical man. Fee *nil*.

What, on the other hand, in spite of this treatment, has the medical man done for the State, and what is he still doing? He is pointing out how the public health may be safeguarded by attention to hygiene. He unostentatiously works away at ascertaining the cause and treatment of disease. He gives ambulance and other lectures for the benefit of the public, and in innumerable other ways assists the State. The time has come when we must by united effort teach the powers that be that we refuse to work for nothing. If we combine, our voice must be listened to. The more we do for nothing, the more we may do. Let us steadfastly set our faces against these socialistic abuses, which are so fast growing apace. Let us teach the State that it has a duty to perform to not only the working but also to the professional classes. The medical man may toil morning, noon, and night; what cares the State so long as it obtains his services for nothing? Has this present Government, which boasts so freely of its beneficent work, passed one measure to benefit the condition of a profession which holds in its power the very life of the people? The time has now come for action. Let the Divisions rise to a sense of their duty, and in no uncertain voice demand that social progress shall not be made at the expense of the hardest worked and worst paid profession in the world.—I am, etc.,

PESSIMIST.

Medico-Legal.

DEATH UNDER STOVAINE.

At Battersea, on January 22nd, an inquest was held by Mr. John Troutbeck with regard to the death of a man aged 72, a house painter, who died while under the influence of stovaine at Wandsworth Infirmary. Dr. W. L. MacCormac, the assistant medical superintendent of the infirmary, according to the report in the *Wandsworth Borough News*, said that an operation became necessary if the patient's life were to be prolonged. He suffered from enlargement of the prostate, with great pain, and because he had a senile heart and diseased lungs stovaine by subcutaneous injection was chosen in preference to a general anæsthetic. It was injected between the third and fourth lumbar spines, and loss of sensation below the level of the injection began in about eight minutes. Having made the injection, Dr. MacCormac and his assistant washed out the patient's bladder, and while this was being done the patient, who was stone deaf, exchanged thoughts with him by gestures. Before the operation

was begun the patient's face was noticed to be very pallid, and he yawned immediately. Failure of the circulation and respiration followed, and the ordinary stimulants failing to combat this collapse, death occurred half an hour later. The yawning began about ten minutes after the stovaine had been injected. He attributed death to anaemia of the brain, and connected it with the stovaine. He could not see what else caused the yawning. But the only reason why he connected death with the stovaine was because death followed so soon after its use. In reply to a question by the coroner whether it would be correct to say he died from anaemia of the brain while he was under the influence of stovaine, Dr. MacCombe said he would be glad if he would put it that way. Dr. Freyberger, who made the necropsy, gave the cause of death as bloodlessness of the brain in consequence of failure of the heart while the man was under the influence of stovaine, and stated that he had known two similar cases.

The jury returned a verdict of "Accidental death," and expressed the opinion that everything possible had been done for the patient.

POST-MORTEM EXAMINATIONS FOR CORONERS IN IRELAND.

DR. JAMES M. HERON, J.P. (London, S.W.), writes: In the *BRITISH MEDICAL JOURNAL* of January 23rd, in reply to "R. C. P.," you state: "So far as we are aware, no medical officer of a workhouse or county infirmary in Ireland has obtained a fee for making a post-mortem examination or for giving evidence regarding the death of any person dying in either institution." In one case, during the summer of 1908, at an inquest held in the County Infirmary, Downpatrick, by two Justices of the Peace (Messrs. McLean and Denvir) respecting the death of a patient who died after admission, Dr. Elwood, assistant surgeon to the infirmary, was called as a medical witness and was paid a fee for giving evidence as to the cause of death. I had been asked to act, as one of the justices of the county, at the inquest, but was unable to do so owing to another engagement. The inquest was held during the absence of the coroner for the division. Perhaps this case may serve as a precedent for use hereafter by the Medical-Political Committee of the Association. The payment of this fee passes under review by the auditor, but I do not think that he will undertake to investigate the circumstances of each inquest held, but must be satisfied by the certificate of the expenses incurred by the coroner in holding an inquest, or in this case by his substitute—namely, the court formed by two justices of the peace. The payment interested me greatly at the time of the inquest as I knew it to be illegal, but I have satisfied myself that the payment was made.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

CARDS AND FEES.

SOLEMAN asks (1) whether a newly-established practitioner should leave cards or a card when making his courtesy call; (2) whether fees for attendances at inquests made by a locumtenens belong to the latter or to the principal.

*(1) He should leave one card. It is not usual for a gentleman making a social call to leave more than one card. (2) If the attendances at inquests take place during the time the locumtenens is in the service of the principal the fees must be paid to the latter.

Public Health

AND

POOR-LAW MEDICAL SERVICES.

SCHOOL CLOSURE.

M. O. H.—Article 57 of the Code is as follows: "If the sanitary authority of the district in which the school is situated, or any two members thereof, acting on the advice of the medical officer of health, require either the closure of the school or any department thereof, or the exclusion of certain children for a specified time, with a view to preventing the spread of disease or any danger to health likely to arise from the condition of the school, such requirement must at once be complied with." This article has usually been interpreted as meaning that a sanitary authority or two of its members could only insist upon the closing of a public elementary school provided the medical officer of health advised that such school should be closed. There are conceivable circumstances—such as the absence through illness of the medical officer of health or there being at the time no medical officer of health in office—which would necessitate the sanitary authority or two of its members issuing a closing order without acting upon the advice of the medical officer of health.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Natural Science Scholarships.

THE following scholarships are announced for competition in Natural Science: March 9th, Keble College; March 16th, Merton, Exeter, and New Colleges; June 29th, Brasenose College.

Degree in Medicine.

The degree of B.M., B.Ch., has been conferred on Cyril D. H. Corbett, of University College.

UNIVERSITY OF CAMBRIDGE.

Third Examination for Medical and Surgical Degrees, Part II.

THE examination in the Easter Term will in future begin on the last Tuesday but one before the end of term.

H. Scott, B.A., Trinity College, has been appointed Curator in Zoology in place of D. Sharp, M.A., F.R.S., who has resigned.

The following degrees were conferred on January 28th:

M.D.—H. H. Clarke, Trin.; H. H. Dale, Trin.; H. Rischbieth.

M.B.—G. F. Greenwood, Sid. Suss.

B.C.—H. B. Elton, Gonv. and Cai.; W. W. Treves, Gonv. and Cai.;

A. E. M. Woolf, Eum.

The next examination for the Third M.B., Part II, will take place in the Easter Term on Tuesday, June 15th.

UNIVERSITY OF MANCHESTER.

The Botanical Department.

MR. W. H. LANG, M.B., D.Sc., Lecturer in Botany in the University of Glasgow, has been appointed to the new Chair of Cryptogamic Botany at the Manchester University. The Chair has been founded under a bequest of the late Thomas Earker, formerly Professor of Mathematics at Owens College. Dr. Lang was a research scholar of the Glasgow University, and has made a special study of the cryptogams, travelling for the purpose in Ceylon and the Malay Peninsula. His appointment is especially suitable as the late Professor Earker was interested in the Bryophyta, of which Dr. Lang has made a special study. Dr. Lang has for several years been an external examiner at the Manchester University and is now an examiner in the University of London.

Miss M. Stopes, D.Sc., Ph.D., has been appointed Special Lecturer in Palaeobotany in the university. Some time ago Miss Stopes was assistant lecturer in the university and resigned the position in order to visit Japan, where she made a collection of fossil plants from the mesozoic coal measures. She did good work at the laboratory for botany in the University of Tokio, where she gave a course of lectures on fossil plants.

Pro-Vice-Chancellor.

Professor H. B. Dixon has been elected Pro-Vice-Chancellor of the University in place of Professor Horace Lamb, whose term of office has expired.

Lancashire Education Committee.

THE Vice-Chancellor has again been nominated as representative of the University on the Lancashire Education Committee.

UNIVERSITY OF BIRMINGHAM.

Number of Students.

THE registered students of all kinds last session numbered 960, of whom 507 were matriculated students proceeding to either a junior or senior degree. They were distributed as follows, the numbers in previous years being given for comparison:

	1903-4.	1905-6.	1907-8.
Faculty of Science	99	177	226
Faculty of Arts	85	140	180
Faculty of Commerce	13	22	24
Faculty of Medicine	89	79	77
Total matriculated	286	419	507
Unmatriculated	554	483	453
Total	840	902	960

In the Faculties of Science, Arts, and Commerce there were 450 male and 279 female students, and in the Faculty of Medicine 170 male and 43 female students.

Income and Expenditure.

THE following are particulars of income and expenditure for the year ending September 30th, 1908: Income—General endowment, £5,343 3s. 3d.; special endowments, £1,955 0s. 2d.; Government grants, £11,000; local authorities' grants, £7,583; students' fees, £13,865 11s. 4d.; engineering testing fees, £9 15s. 6d.; bacteriological department, £1,395 19s. 2d.; brewing school, £1,368 17s. 5d.; sundries, £556 7s. 4d.; total, £47,530 2s. 3d. Expenditure—Principal's department, £2,643 9s. 4d.; Vice-Principal's department, £656 6s. 8d.; stipends of professors, lecturers, and demonstrators, £24,260 19s. 4d.; examinations, £2,358 11s. 7d.; degree congregation, £35 0s. 7d.; one-third of membership fees for university societies, etc., £181 5s. 8d.; departmental expenses, £7,580 18s. 7d.; library, £373 17s. 3d.;

interest on mortgage and bank interest, etc., £2,078 16s. 11d.; general management, £3,378 14s. 4d.; maintenance, £4,113 14s. 10d.; brewing school, £1,556 14s. 8d.; annuities payable under the will of the late Sir Josiah Mason, £152; sundries, £454 18s. 10d.; Queen's College Hall of Residence, £1,279 9s. 7d.; total, £52,264 2s. 10d. Deficiency on the year, £4,934 0s. 7d.

Proposed Pension Scheme.

The council of the university approved a pension scheme, limited to full-time professors and some of the principal officials. At the age of 65 a contributor may retire and be entitled to an allowance of one-sixtieth of his then salary for every year's service with the university, with a maximum of half salary. Such a scheme can be made self-supporting with regard to all members entering the service after it is established on a contribution of 10 per cent. of salary, of which 4 per cent. will be contributed by the professors and 6 per cent. by the university. The difficulty is to meet the claims of the present staff, many of whom are approaching superannuation age, and who cannot contribute except during the years which remain to them before attaining 65. Before the liabilities to the present staff are disposed of, the university will have to provide sums which vary considerably every year, a maximum being about £1,100 in 1925, diminishing gradually after that date, and finally disappearing twenty years later.

Hall of Residence for Women Students.

The new hall of residence for women students was taken over by the university on January 1st, 1909. The buildings are situated on a site on the eastern side of Edgbaston Park Road, opposite the new university buildings. The land has been granted by Lord Calthorpe on a lease for ninety-nine years, at a ground rent of about £30 a year. The buildings have cost £16,000, and donations have been received amounting to £12,500. They provide accommodation for sixty students. The new hall is under the direction of Miss S. Margery Fry as warden. The buildings, lease, and funds have been offered as a free gift to the university.

The New University Buildings.

The total cost of the present new buildings of the university, together with their equipment and the laying out of the site, will be, when completed, just over £500,000, to which must be added another £50,000 to provide for the further expenses of staff and maintenance. Towards this sum only about £300,000 can be provided out of the funds at the disposal of the council, so that another £250,000 is required at once. This sum the council is most anxious to raise before the middle of this year, when it is hoped that the King may consent to open the new buildings in person. Sums amounting to £58,900 have been already promised, including £30,000 from Sir Charles Holcroft, Bart., and £10,000 from the Lord Mayor (Alderman G. H. Kenrick).

UNIVERSITY OF LIVERPOOL.

The following diplomas were granted by the Senate on January 27th:

Diploma in Tropical Medicine.—John Rhodes Dickson, M.B., C.M. Edin.; Henry Joseph Glover, M.B., C.M. Edin.; Francis Wood Graves, M.B., Ch.B. Edin.; James Herbert Hugh Harrison, M.R.C.S., L.R.C.P.; Jamshed Byramji Manna, L.M.S. Bombay; Charles Ross Pearce, M.B., C.M. Edin.; Alexander Frederik Schoorl, M.D. Leyden; George Edward Stewart, M.B., C.M., F.R.C.S. Edin.

Diploma in Public Health.—Charles Samuel Brewer, L.R.C.P., L.R.S. Edin.; Herbert Macpherson Cargill, M.B., Ch.B. Edin.; Katherine Rosebery Drinkwater, L.S.A., M.B., B.S. Lond.; Bertram Thomas Johnson Glover, M.B., Ch.B. Liverpool; Clive Oswald Stallybrass, M.R.C.S., L.R.C.P., M.B., B.S. Lond.; John Teare, M.B., Ch.B., Victoria and Liverpool.

UNIVERSITY OF EDINBURGH.

Additional Examiners.

At the January meeting of the Edinburgh University Court the following additional Examiners were appointed: Professor Arthur Thomson, University of Oxford (Anatomy); Professor John B. Haverfield, University College, Cardiff (Physiology); Professor James Martin Beattie, University of Sheffield (Pathology); Dr. William Fordyce, Edinburgh (Midwifery); Dr. William Russell, Edinburgh (Clinical Medicine).

Gift to the Natural Science Laboratory.

It was reported that Emeritus Professor Crum Prown had presented to the University, for the Department of Natural Science, a Natterer's apparatus for the liquefaction of gases.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary quarterly comitia was held at the college on Thursday, January 28th, the President (Sir R. Douglas Powell), in the chair.

Lecturers.

The President announced that he had nominated Dr. G. H. Savage as Harveian Orator and Dr. Lindsay as Bradshaw Lecturer for 1909, and Mr. Foulerton, F.R.C.S., as Milroy Lecturer for 1910.

Swiney Prize.

The President further announced that the Swiney Prize had been awarded to Dr. C. A. Mercier for his work on criminal responsibility.

Membership.

The following gentlemen were admitted Members of the College:

George Augustus Auden, M.D. Cantab., L.R.C.P.; Francis William Clark, M.D. Durh., L.R.C.P.; John Frederick Halls Dalry, M.D. Cantab., L.R.C.P.; Robert McCarrison, M.B. R.U.I.; Edward Fretson Skinner, M.B. Cantab., L.R.C.P.; Arthur Lionel Hall Smith, M.B. Cantab., L.R.C.P.; James Aubrey Torrens, M.B. Lond., L.R.C.P.

Diplomas in Public Health.

In conjunction with the Royal College of Surgeons diplomas in Public Health were granted to the following gentlemen:

Alfred Ball, M.B., B.S. Lond., L.R.C.P., M.R.C.S.; Robert James Bethune, M.D., B.Ch. R.U.I.; Arthur Burnell Carter, L.R.C.P., M.R.C.S.; Bertram Walter Cherrett, M.B., B.S. Lond., L.R.C.P., M.R.C.S.; James Clark, M.D., Ch.B. Aberd., M.R.C.P. Lond.; James Alfred Patrick Cullen, M.B. Lond., L.R.C.P., M.R.C.S.; Leonard Fabian Hirst, M.B., B.S. Lond., L.R.C.P., M.R.C.S.; Duncan Matheson Johnston, L.R.C.P., M.R.C.S.; Andrew Alexander McWhan, M.B., Ch.B. Glasg.; Frederick Septimus Penny (Captain R.A.M.C.), M.B. Lond., L.R.C.P., M.R.C.S.; Norman Hamilton Walker, M.B., B.S. Lond., L.R.C.P., M.R.C.S.; Arthur Harold Wilson, L.R.C.P. and S. Edin., L.F.P. and S. Glasg.; Subrahmanyan Yenamandram, L.M. and S. Madras.

Licence.

The licence of the College was granted to eighty-one gentlemen.

Communications.

The following communications were received:

1. From the Secretary of the College of Surgeons, reporting proceedings of their Council on January 14th, 1909.
2. From the Home Office, enclosing for the information of the College a letter from the organizing committee of a proposed international congress for improving the condition of the blind, to be held in Naples, March 30th to April 3rd, 1909.
3. From the Dean of the Faculty of Medicine, University of Edinburgh, proposing the third week of June as the date of the next examination for the Murchison Scholarship, to be held in Edinburgh this year. This was agreed to for the present year, and the fixing of a permanent date, convenient both to the College and the University, was deferred.
4. From the Rector of the University of Geneva, inviting the College to send a representative to join in the commemoration of the 350th anniversary of its foundation, and of the 400th anniversary of the birth of Calvin, the founder, to be held in Geneva, July 7th to 10th, 1909. The invitation was accepted, and it was left to the President to nominate a representative.

Councillors.

On the nomination of the Council Drs. Sidney Phillips, W. Pasteur, Sidney Martin, and A. E. Garrod were elected Councillors in the room of Drs. Osler, Crocker, Tooth, and Acland, who retired by rotation, and Sir William Allchin was elected a Councillor for one year in the place of Dr. C. E. Beever, deceased.

Central Midwives Board.

Dr. Champneys was re-elected a representative of the College on the Central Midwives Board for one year from April 1st next.

University of Birmingham.

Dr. Theodore Williams, who retired by rotation, was re-elected a representative of the College on the Court of Governors of the University of Birmingham.

Reports.

The following reports were received:

1. From the Committee of Management, dated December 18th, 1908, recommending that (a) Whitgift School, Croydon, and King's College School, Wimbledon, be added to the list of institutions recognized by the Examining Board in England for instruction in chemistry and physics; (b) the Municipal Technical Institute, Portsmouth, which is already recognized for the courses of instruction in chemistry and physics, be also recognized for instruction in biology; (c) the Medico-Chirurgical College, Philadelphia, be added to the list of institutions at which the curriculum of professional study required for the diplomas of the Royal Colleges may be pursued, and whose graduates may be admitted to the Final Examination of the Examining Board in England on production of the required certificates of study.
2. The annual return by the examiners of the results of the examinations for the licence in the year 1908.

Library.

Books and other publications presented to the library during the past quarter were received, and thanks returned to the donors. A special vote of thanks was passed with acclamation to Sir William Allchin for a valuable gift of a twelfth century manuscript copy of the *Regimen Sanitatis*.

Obituary.

THOMAS LAURENCE READ, M.R.C.S.,

KENSINGTON.

A LARGE circle of friends and patients will learn with sincere regret of the death of Thomas Laurence Read, who had been in active practice until Christmas Eve, when he had a slight attack of aphasia without any lasting hemiplegia; from this he was rapidly recovering, and was, indeed, planning a change to Brighton, when on January 20th he had a hemiplegic seizure on the left side. From this he partially rallied, and his death, which was quite sudden and unexpected, occurred on January 28th, at 2 a.m.

He was born in Hornton Street, Kensington, on August 15th, 1833, and was therefore in his 76th year. Few even among those who had known him for many years realized that he had reached such an advanced age, for he was alert and full of energy to the very end of his active career. After being educated at the Old Hall, St. Edmunds, Ware, he was apprenticed to his father, who was a popular practitioner in Kensington, and a friend of Thackeray and Dickens. His medical education was completed at St. George's Hospital, where he was a contemporary of Henry Gray the anatomist. To the hospital he was always warmly attached, and his genial face was familiar to many generations. In 1856 he became a Member of the Royal College of Surgeons, and immediately started in practice with his father in Campden Hill. A little later—about fifty years ago—he settled in the house in Petersham Terrace in which he died; the house was then newly built and surrounded by market gardens. The alterations in the surroundings of his home correspond with the vast changes which he had witnessed during more than fifty years' general practice. To the practice of his profession he gave unreservedly all—and it was much—that lay in his power. It is indeed remarkable how well he bore his incessant hard work and worry, for his holidays were scanty, and he devoted himself heart and soul to the interests of his patients. As a practitioner he was as sound as he was straight. He had no need to cultivate any artificial bedside manner; his own genial and naturally sympathetic personality, of which he seemed and was entirely unconscious, made him welcome wherever he went; his patients valued him as a doctor, and felt that he was a friend. That he was a representative of the best type of general practitioner was recognized by his election in this capacity as a member of the Council (1901-3) and of the House Committee (1902-3), of the Royal Medical and Chirurgical Society, and of the Council of the Royal Society of Medicine.

Mr. Read lost his wife some twenty years ago, and leaves a large family. He has had two sons in the profession; the elder died some years ago at Odiham, the younger has for some years been in partnership with his father.

Sir THOMAS BARLOW, Bart., K.C.V.O., writes: Everybody who knew Read trusted him. The keynotes of his character were his practical wisdom and his genuine kindness of heart. These qualities contributed to make him a fine example of the best type of general practitioner. For, although he was always grateful and appreciative of help in diagnosis and suggestion from any of his *confères*, yet his acquaintance with his patients was so intimate and his knowledge of therapeutics was so sound that he seemed almost intuitively to realize the limits of what could be attempted by way of treatment, and he was so thorough and unselfish that he had no need for flattery and honeyed speech. He keenly enjoyed the friendship of all sorts and conditions of men, but most of all that of his professional brethren, and his devotion, through a long life, to his old medical school and everything connected with it was remarkable. Read "warmed both hands at the fire of life"; he was in harness almost to the end, and he leaves a vacant place in the affectionate memory of all who knew him which will long remain unfilled.

We are indebted to Mr. Read's old friend, Mr. Pickering Pick, for the following note:

He was a very prominent general practitioner, who practised his profession in Kensington for more than half a century. In fact, he has been associated with Kensington all his life, his father having been in practice in that place at the time of his birth. Read will be much missed and mourned by a large circle of patients and friends; his genial, sympathetic manner, and his kindness of heart endeared him to all with whom he came in contact.

JOHN EVAN SPICER, M.A., M.D., B.C. CANTAB.,

MEDICAL REGISTRAR TO THE LONDON HOSPITAL.

On January 13th, in Switzerland, John Evan Spicer was killed by an avalanche. By his death the medical profession and the London Hospital lost one of their most promising men, one who would have taken a front place in the ranks of physicians and public men.

He was born at Dulwich in 1875, and educated at Clifton and Cambridge; he entered the London Hospital in 1900, and, after holding all the resident appointments, he was appointed Medical Registrar in June, 1908. While working at the hospital he contributed to medical literature "An Unusual Case of Dilatation of the Stomach" (*Clinical Society's Transactions*, vol. xxxix), "Three Cases of Malformation of the Tracheo-Oesophageal Septum" (with Dr. Keith) (*Journal of Anatomy and Physiology*), "A Case of Abnormal Development of the Oesophagus" (*Lancet*, 1907), "Imperforate Urethra in the Fetus as a Cause of Dystocia" (*Proceedings of the Royal Society of Medicine*).

Although Spicer's experience and knowledge of medicine were great, yet the sense of loss which spread over the hospital when the news became known was a markedly personal one. More even than the loss of the physician the loss of the man was deplored.

At the memorial service held by the Free Church Camps for Schoolboys a large gathering of men were present, and the tributes to his memory by Sir J. W. Bann in the *Daily News* and *British Weekly*, and the sincere expressions of grief which came from all associated with him in work, testify to the many interests he had at heart.

All through his hospital career the great feature of his life was ardour. He was more than keen. Whether going round with the clerks or dressers in the morning, there was an intense zeal about all his work which spread to all with whom he was associated. His knowledge of the patients was not confined to the medical aspect, for many is the man or woman who was helped materially, while in hospital and after discharge, by Spicer to keep things going till completely restored to health and work. There were many sad hearts in humble homes when the sad news became known. Between his terms of residence, working in the post-mortem room or anatomical laboratory, he displayed the same ardour in all he undertook, and no day's work was too heavy. He excelled in powers of organization in all his work at the hospital, whether teaching, investigation, or recording; in conducting the locumtenent agency, in arranging Christmas troupes, in arranging particulars for camps, those powers shone out, and have made the labours of those who will attempt to take up his work so much simpler. Spicer was magnificent; of wide experience in medicine here and abroad; exceptionally well read, constantly cheerful even when dead tired, ever ready with jest, or song, or help, his departure has left a gap which no man can fill; but at the root of it all was an earnest Christianity which impressed all his fellow-workers with its reality and sincerity. The memory of that meeting at Whitefield's Tabernacle, when, in spite of inclement weather and short notice some three or four hundred of his fellow campers gathered together to do homage to his memory was a grand testimony to his position among the young men of the Free Churches. The testimonies which were borne there to his ardour, organization, cheerfulness, and Christianity in camp life were in keeping with the whole of his life at Dulwich, and in the hospital, and in spite of the deep feeling shown there was the predominant assurance that his life had not ended; but would remain in its influence for many years to come. So is it at the hospital—we miss the square-shouldered form, the fine head, the manly step, but his influence on his clerks, dressers, and fellow residents will ever remain as a witness to the life of a good man.

R. M.

GEORGE ELLIS, M.B.Dub., F.R.C.S.I.,

DUBLIN.

THE medical profession of Ireland lost its oldest member in the person of Dr. George Ellis, who died in Dublin on January 27th, having attained his 100th year. He retired from practice no less than forty years ago, being possessed of ample means. Even the older members of the senior group of the profession now living did not know Dr. Ellis, for although he continued to take interest in the progress of medicine, he did not attend the meetings of societies. He was, however, known to some, and was much respected. He does not appear to have held any public appointments.

Dr. Ellis was educated in Trinity College, where he took the degrees of A.B. and M.B. in 1834. He became Fellow of the Royal College of Surgeons in 1844. His contributions to the journals were few, but in one he strongly advocated the use of rennet wine, which he prepared by adding sherry to pieces of the stomach of a newly-killed calf, and allowing it to rest in a bottle for three weeks. He gave this wine to those, especially medical men, "who were very liable to suffer from gastric trouble through worry of mind and body and irregular hours for meals and sleep." He was the author of *Irish Ethnology, Socially and Politically Considered*.

THE death has taken place at Oyne, Aberdeenshire, of Dr. DAVIDSON, who retired from general practice some years ago. He was a graduate of Aberdeen University, and held important appointments, first in Egypt and afterwards in Australia. In consequence of a breakdown in health he returned to Aberdeen, and, after a period of rest, practised in that city. His health again threatened to give way; he retired to Oyne about five years ago. Dr. Davidson gave much time and attention to the cultivation of roses, a subject on which he was an authority.

The Services.

INDIAN MEDICAL SERVICE.

THE result of the January examination was announced on January 30th, 1909. There were 39 candidates, of whom 33 ultimately entered for the examination; of these 31 qualified, the first 12 being admitted as Lieutenants-on-Probation, while one withdrew during the examination. The names of the successful candidates, with the marks obtained by each out of a possible total of 5,100, are given below, together with their degrees and medical schools.

Name.	Degrees, etc.	Medical School.	Marks.
H. C. G. Semon ...	M.B., B.Ch.Oxon., M.R.C.S., L.R.C.P.	Oxford University; University College Hospital, Freiburg University, Germany	4,016
V. B. Gokhale ...	M.R.C.S., L.R.C.P., L.M. and S. Bombay	Grant Medical College, Bombay; King's Col- lege, London; Univer- sity College Hospital	3,633
A. M. Jukes ...	M.D., B.S.Lond., D.P.H.Cantab.	St. Bartholomew's Hospital	3,566
G. G. James ...	M.B., B.S.Lond.	University College, Cardiff; Westminster Hospital	3,504
W. D. Keyworth ...	B.C.Cantab.	Cambridge Univer- sity; Charing Cross Hospital	3,381
B. Gale ...	M.B., Ch.B.Glas.	Glasgow University	3,319
J. H. Horne ...	M.B., Ch.B.Edin.	Edinburgh University	3,312
H. H. Kind ...	M.B., B.S.Lond.	St. Bartholomew's Hospital	3,280
M. D. A. Kureishi ...	M.R.C.S., L.R.C.P.	Tabernacle Medical College; King's College Hospital	3,231
R. E. Flowerden ...	M.B., Ch.B.Aberd.	Aberdeen University;	3,225
A. J. Lee ...	M.B., B.S.Lond.	St. Thomas's Hosp. University Coll. Hosp.	3,194
I. G. B. Shand ...	M.B., Ch.B.Edin.	Edinburgh Univ.; Extra Mural School of Medicine, Edinburgh	3,188

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL CHANGE OF ADDRESS.

THE offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL have been removed to 429, Strand.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

SUFFERER asks for advice as to the prevention and treatment of attacks from which he has suffered four or five times a year. The last attack began after a deposit of urates for several days, the symptoms being soreness and dryness of the throat, the soft palate and the uvula being congested, intense frontal headache, aching in the limbs and slight shivering, with, on this occasion, no elevation of temperature, although in other attacks it is raised to 101°. There ensues suddenly profuse nasal discharge without odour, with morning cough, which is relieved by expectoration of a large quantity of white frothy mucus. The cough, nasal discharge, and lassitude continue for from ten days to three weeks. Of the many drugs tried, he has derived greatest benefit from sodium salicylate.

ANSWERS.

SENEX.—South Formosa is by no means an unhealthy place, and the climate is fair. The means to be adopted for the preservation of health in the tropics will be found in any of the works on tropical medicine or tropical hygiene. The following may be mentioned: Professor Simpson's *Maintenance of Health in the Tropics* (London: Bale, Sons and Danielsson, 1905, 2s. 6d.), and *The Principles of Hygiene in Tropical and Sub-tropical Countries* (London: Bale, Sons and Danielsson, 1908, 15s.), by the same author. If the emigrant is a medical man, he should take Manson's *Tropical Diseases*. Fourth edition (London: Cassell and Co. 1907, 12s. 6d.), and Daniels and Stanton's *Laboratory Studies in Tropical Medicine*. Second edition (London: Bale, Sons and Danielsson, 1907, 16s.).

TREATMENT OF TAPEWORM IN CHILDREN.

DR. J. COCKBURN SYSON (Glasgow) writes: A patient of mine (girl) first exhibited symptoms of *Taenia solium* by passing segments of the parasite at the age of 18 months. During the past nine and a half years—she is now 11—repeated attempts have been made, without success, to dislodge the worm. All the usual anthelmintics were tried. Reading of filmaron in the JOURNAL of January 16th, I procured the drug and administered it according to directions. A few hours afterwards about 2 ft. of worm were dislodged, including the head.

FIRST-AID LECTURES.

J. N.—In deciding what fee to ask for a course of first aid to the employees of a company, the position of the company and the nature of the work might be taken into consideration, as well as the amount which the lecturer might be able to make by his practice in the time which he must give up to the class. If the work is hazardous, it is to the interest of the employers that the men should be instructed in first aid. Generally speaking, it is fair to give a course to working men, when the expenses are paid by the employers, at half fees—namely, 10s. 6d. for each meeting, or £2 12s. 6d. to 3 guineas for the course of five or six meetings.

LETTERS, NOTES, ETC.

ERRATA.—In line 2 of the fourth paragraph of Dr. Harold Kerr's letter on The Home Treatment of Scarlet Fever (BRITISH MEDICAL JOURNAL, January 30th, p. 307), the name "Stickler" is incorrectly printed "Hickler." In the following letter on the same subject, by Dr. Percy Newell (p. 308), the special oil referred to should have, been termed "oleusaban," not "oleusanban," as printed.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	0 4 0
Each additional line	0 6
A whole column	2 13 4
A page	8 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at Postes Restantes addressed either in initials or numbers.

An Address

ON

THE SIGNS OF EARLY DISEASE OF THE THYROID GLAND.

DELIVERED AT A COMBINED MEETING OF THE BURNLEY AND DISTRICT MEDICO-ETHICAL SOCIETY, AND BURNLEY DIVISION OF THE BRITISH MEDICAL ASSOCIATION.

By GEORGE R. MURRAY, M.A., M.D.CAMB.,
HON. D.C.L.DURH., F.R.C.P.,

CONSULTING PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE;
PROFESSOR OF SYSTEMATIC MEDICINE, VICTORIA UNIVERSITY
OF MANCHESTER; PHYSICIAN TO THE MANCHESTER
ROYAL INFIRMARY.

In many diseases which develop gradually and run a chronic course the earliest signs of ill-health are apt to be overlooked. The textbooks, as a rule, describe a disease as it appears in its typical form, while insufficient attention is paid to the symptoms of the early or mild forms of the malady. It thus happens that a disease may have made considerable progress before it is recognized, and so valuable time is lost, during which suitable treatment might have been applied.

I propose, therefore, to-day to draw your attention to some of the signs of early thyroidal disease, which, though by no means rare, are not as well known as they might be.

In diseases of the thyroid gland symptoms of two kinds may occur. In those in which the gland is increased in size there may be local symptoms due to the enlargement itself. These are mechanical in origin, and are the result of the pressure exerted by the goitre upon neighbouring structures in the neck. The other symptoms are due to variations in the functional activity of the gland induced by the structural changes which occur in it.

When the various pathological changes to which the thyroid gland is liable are fully developed the symptoms are so marked and striking that the diagnosis presents no difficulty. The various forms of goitre are readily recognized as such, the real difficulty being not to determine whether the tumour is a goitre or not but to distinguish between the different varieties of goitre which may occur. A well-marked case of exophthalmic goitre, of myxoedema, or of cretinism is readily diagnosed, provided the observer is familiar with the general aspect of the disease. On this occasion we may with advantage consider some of the early symptoms presented by these diseases by which we may recognize them at the earliest possible moment and so lose no valuable time in applying the most appropriate treatment. The importance of this is twofold. First, one finds that patients in the earlier stages of thyroidal disease may go about for a considerable period without the true nature of the disorder being recognized; secondly, the value of early treatment is so great, both in diminishing the period of ill-health and in obtaining a better result than when it is deferred until the disease has become fully established.

Some of these cases with slight symptoms are in an early stage of a more severe attack which will follow if treatment is not successful in checking their further development. Others are mild types of the disease, and may for long remain stationary in this condition. Such cases, both of myxoedema and Graves's disease, have been described by Continental writers as *formes frustes*—an unnecessary term, as they are simply mild cases such as we find in so many other maladies.

As the function of the thyroid gland is to supply an internal secretion which escapes by way of the lymphatics into the blood stream, by which it is distributed to all parts of the body, diseases of the thyroid may be divided into three classes, according to the manner in which this function of the gland is influenced by them. Thus some diseases have no appreciable effect upon the secretory function of the gland; others lower or abolish it according to their severity, and in yet a third class it is greatly increased and possibly perverted as well.

As examples of the first class may be cited uncomplicated acute thyroiditis, simple parenchymatous goitre, and many cases of adenomatous or cystic goitre. The

second class is illustrated by cretinism and myxoedema, and the third by exophthalmic goitre and those cases of goitre in which the "goitre-heart" is present.

SIMPLE PARENCHYMATOUS GOITRE.

The normal thyroid gland is subject to variations in volume, as it may become temporarily enlarged during menstruation or pregnancy, subsiding afterwards to its usual size. Such enlargements are physiological, and occur in response to some temporary stimulus or demand for an increased functional activity. In many cases, however, a simple enlargement of this kind tends to go on increasing in size and becomes pathological. This occurs most frequently in adolescents and young adults, and much more frequently in women than in men. In the early stages the swelling is apt to escape notice unless the thyroidal region is inspected and palpated in the course of a routine medical examination. As the thyroid grows the total circumference of the neck is increased, and the gradual tightening of the collar may first draw attention to the goitre. On inspection the front of the neck looks full and rounded, and the skin is often marked by the pressure of the collar stud. If the patient be made to swallow a mouthful of water the swelling is seen to rise and fall again during the act of deglutition. This movement of the swelling is characteristic of all enlargements of the thyroid gland, unless it is fixed by adhesions, or, as in the case of malignant goitre, by the extension of the disease through the capsule into the surrounding parts. During this movement the horseshoe shape of the uniformly enlarged gland is often clearly to be seen. On palpation the swelling will be found to take the same shape as the thyroid gland, though it will be several times as large. It is firm and elastic in consistence, and there is no tenderness on pressure. No thrill can be felt, nor is any murmur as a rule audible on auscultation over it. When the goitre has reached a larger size, the veins overlying it may be enlarged and visible; there may be a sense of fullness in the neck and some difficulty in breathing. This, however, is much more common in adenomatous and cystic goitres than in the form under consideration.

This simple parenchymatous goitre may be distinguished from exophthalmic goitre by the absence of tachycardia and other symptoms of Graves's disease, and from enlargement due to the presence of adenomata or cysts by its symmetrical shape, though of course the two forms of enlargement may be combined in the same case.

As this form of goitre is a simple hypertrophy which takes place in response to a demand for increased activity, it is analogous to the hypertrophy of the mammary gland which takes place during pregnancy and lactation. The treatment is therefore on rational lines, and consists in supplying the increased amount of thyroidal secretion which is required from another source. When this is done the gland gradually diminishes in size. If the treatment is commenced at an early stage the gland may return to its normal size. If the hypertrophy has been present for some time the result may not be so good, but a marked reduction in size may be expected in many cases. As an illustration of this class of case I may refer briefly to the case of a girl, aged 13, who was under my care at the Newcastle Royal Infirmary, in which there was a considerable goitre which caused some difficulty in breathing. The total circumference of the neck was 16½ in., and after treatment for eleven weeks it was reduced to 13 in., and the symptoms due to the goitre were removed. In this and other similar cases the question of an operation for the removal of a portion of the goitre to relieve the dyspnoea had been considered, but was obviated by the treatment.

As a general rule, when a goitre is unilateral, the enlargement is due to an adenoma or cyst in one lobe. The size of an adenoma or a cyst would not be affected by thyroid extract. I have, however, seen one interesting case which was sent to me by Dr. A. Smith, of Whickham, in which one lobe alone was enlarged. I regarded this enlargement as being due to an adenoma, and advised its removal, as there were signs of pressure. The patient, however, refused operation, and therefore we decided to try the effect of thyroid treatment. To our surprise, the enlarged lobe steadily diminished in size, and the patient was relieved of her symptoms. This case suggests that a

unilateral goitre may in some cases be due to a simple hypertrophy, and that it is worth while to try the effect of this treatment if there is any doubt as to the cause of the enlargement.

In cases of simple goitre it generally suffices to give from 3 to 5 grains of dry thyroid powder in a tablet each night. In some cases it is advisable to give this dose two or three times daily, provided no marked acceleration of the pulse occurs. If there is no distinct reduction in the size of the goitre after treatment for a month or six weeks, there is nothing to be gained by continuing it further. If there is a decided reduction, it is advisable to continue the treatment for three or four months, so as to obtain its full benefit, and to resume it for a month occasionally if there is any sign of recrudescence.

If goitre is at all prevalent in the district the patient should drink no water unless it has previously been boiled or distilled. The local application of iodine, especially in the form of the red iodide of mercury ointment, is also useful.

MYXOEDEMA.

We may pass on now to the consideration of the mild type of myxoedema which results from a partial fibrosis of the thyroid gland, which occurs not uncommonly in women between 40 and 50 years of age. When the fibrosis is complete, a fully-developed case of myxoedema results. In arriving at this advanced stage of the disease, the symptoms are at first slight. I believe, however, in some cases that the fibrosis of the thyroid is only partial for a long period. In some it possibly never progresses beyond this stage. Thus, we occasionally come across these mild early cases of myxoedema which have been neither recognized nor treated, the result being a prolonged period of ill-health for the unfortunate sufferer, which she might have been saved if the disease had been diagnosed and treated at its commencement.

The symptoms which result from partial thyroidal fibrosis usually come on very gradually, between 40 and 50 years of age, and are not infrequently mistaken for those which so commonly occur in women during the menopause. There is a gradual loss of mental and physical energy, so that every action appears to require a special effort. The result is that the patient's sphere of action becomes more and more restricted. Such patients say they take no pleasure in life and have lost interest in their surroundings. They are apt to shun the society of others and to become depressed and melancholy at times. If by force of will a normal mode of life is continued they will tell you this is only accomplished by a considerable mental effort and expenditure of energy. The memory is often defective, especially for names and for recent events. Slight visual hallucinations are very common. They are rarely complained of, but a clear account of them may be obtained on carefully interrogating the patient. In these slight cases the hallucinations are not, as a rule, so clearly defined as they are in some advanced cases, but take the form of some ill-defined object, indistinctly seen "out of the corner of the eye," like a mouse rapidly crossing the room. Sensations of cold are often complained of, although the temperature of the body may be scarcely, if at all, below normal. The facial appearance is somewhat altered. The cheeks become rounded and fuller, and a central pink flush appears. This change may impart a fictitious appearance of improved health and nutrition, which is liable to be mistaken for such by the friends of the patient, who imagine that she is getting stout and rosy. A careful inspection will, however, show that there is also a small amount of swelling of the eyelids, which has a translucent appearance like the swelling due to a slight subcutaneous oedema, but does not "pit" on pressure. The skin of the face may be rather pale and waxy in appearance, or it may have a pale yellow tinge. The lips are rather swollen and the mucous membrane pale. The eyebrows may be rather scanty, and the forehead is often transversely wrinkled.

The subcutaneous swelling on the body generally is not sufficient to attract the patient's attention, though it may be found on careful examination. In the supraclavicular region the swelling may be quite distinct. The hands are somewhat altered in appearance, the back of the hand being rounded and swollen. The feet often show a similar condition, though the swelling may not be sufficient to

necessitate the use of a larger size of boot, as in the more fully-developed stages of the malady. The skin is rather dry; on the backs of the hands it may be smooth if there is much swelling, or it may be loose and wrinkled, like that on the hand of a washerwoman. A fine desquamation takes place, especially on the legs, the results of which are clearly seen, on removing a pair of black stockings and turning them inside out, as a fine white powder. The hair may partially come out, though its texture may not be appreciably altered.

Such are the main symptoms produced by early thyroidal fibrosis, easily recognized when looked for, but otherwise easily passed over. In doubtful cases a careful examination of the thyroidal region of the neck may show that the gland is diminished in size. As already mentioned, these symptoms are liable to appear at the time of the menopause. When the ovary atrophies at the same time as the thyroid gland, the symptoms of the menopause, such as a feeling of pressure on the top of the head, hot flushes and sweats, may occur in addition to those which are due to the thyroidal fibrosis. The nervous symptoms in each case are somewhat similar. A careful examination of the patient for the slight signs of myxoedema will, however, enable a correct conclusion to be drawn as to the cause of the symptoms complained of.

There is a condition of lipomatosis which I have seen in several cases which closely resembles a slight form of myxoedema, which has not as yet received adequate recognition. In this there is an elastic subcutaneous swelling like that which we see in myxoedema, but differing from it in distribution. The skin is not dry as it is in true myxoedema. The hair and nails are unaffected. The swelling is generally more localized than in myxoedema. One case which appeared to be of this type occurred in a lady of 31. There were well-marked swellings in the supraclavicular region, over the deltoids, over the hips and upper gluteal region. The swelling was greater on the right side of the body than the left. The circumference of the right arm at the level of the insertion of the deltoid was 13 in., of the left 12½ in. The circumference of the middle of the right thigh was 22½ in., of the left 20½ in. In these cases the swelling has no sharp edge, but gradually shades off, and it is quite painless. In addition to the situations already mentioned, it may be present on the backs of the hands. As a rule the face is not affected; if it is the swelling is only in the cheeks, which have no central flush, and there is no swelling of the eyelids as in myxoedema. When the swelling covers a considerable area, as it does on the outside of the thigh, the skin is dimpled when it is pinched up between the finger and thumb. The final test is the action of thyroid extract. It will be found that even after taking two or three times as much thyroid extract as would suffice to relieve a true myxoedema in the course of a month, these swellings are only slightly, if at all, diminished in size. They appear to consist of irregular deposits of subcutaneous fat, and are possibly more closely allied to the swellings which occur in adiposis dolorosa, from which, however, they differ in size and in the absence of all pain and tenderness.

The treatment of these cases of mild myxoedema is simple. Thyroid extract should be given in doses of 5 minims of liquor thyroidei each night for a month. If decided improvement has then taken place this dose may suffice, if not, it is advisable to increase it up to 10 minims, and to continue this dose until all the symptoms have disappeared. The permanent dose will be from 5 to 7 minims, for it must be clearly understood, and also explained to the patient at the outset, that the treatment must be continued for the rest of her life. If, later on, the partial fibrosis becomes total it will be necessary to increase the permanent dose to 10 minims each night. This amount of the extract appears to correspond to the daily output of secretion from an average normal gland. This statement is based on the fact that my first case of myxoedema, in which I believe there is now no active portion of the gland left, has been kept quite free from myxoedema for more than seventeen years by this dose taken six nights in the week.

EXOPHTHALMIC GOITRE.

We have now to consider the effects of hypersecretion of the thyroid gland, just the opposite condition to that

which obtains in myxoedema. The result of excessive secretion is best seen in a typical case of exophthalmic goitre. The microscopical appearance of the enlarged thyroid gland exhibits changes which indicate that there is an enormous increase of functional activity. Fully-developed exophthalmic goitre is so characteristic that no description is required. The goitre, exophthalmos, rapidly-beating heart, with nervousness, tremors of the hands, and emaciation, make up a clinical picture which can be readily recognized. It is, however, to the less obvious cases that I wish more particularly to draw your attention. In the first place I may remind you that in more than a quarter of all the cases of definite Graves's disease one symptom, and that the most obvious of all, the exophthalmos, is absent. Thus in 170 of my own cases² exophthalmos was present at some stage of the disease in 123, but in 47, or more than 25 per cent., there was no exophthalmos at all. Why this remarkable sign is present in one case and yet absent in another which otherwise has similar symptoms cannot at present be explained. The whole pathology and causation of the exophthalmos is still obscure. Of the various explanations of it which have been given, the only one which is tenable is that which attributes it to an abnormal development of the retro-bulbar fat in the orbit. At an autopsy this mass of fat presents a striking appearance, and may be seen even in cases in which there is such a degree of general emaciation that hardly any fat is visible in other parts of the body. The fat from one orbit alone in one of my cases weighed 1 oz. A simple experiment will show how such a mass of fat produces exophthalmos. The head of a dead sheep or smaller animal, such as a guinea-pig, will serve the purpose quite well. The upper part of the skull and the brain are removed so as to expose the optic foramen. A small trocar and cannula are pushed through the optic foramen alongside the optic nerve until the orbit is reached. The trocar is withdrawn, and a warm syringe filled with melted paraffin or agar-agar to which some colouring matter has been added is attached to the cannula. The fluid is then injected into the orbit behind the eyeball, which gradually begins to protrude, and any degree of exophthalmos can be produced according to the amount of fluid injected. Later the orbit can be opened and the distribution of the solidified agar-agar examined. The exophthalmos thus persists after death, which it would not do if it was caused by vascular congestion or spasm of Müller's muscular fibres.

Exophthalmos is so striking a symptom that when present the diagnosis is easy. It is, however, to the cases in which this symptom is absent that I wish to direct your attention. When there is no actual exophthalmos there may be a rather staring expression in some cases, which is due to a slight spasm of the elevator of the upper eyelid (Stellwag's sign). This may be either constant or intermittent. When it is persistent there is a notable absence of blinking, the palpebral fissure is rather wider than it should be, and the effect is to give a rather startled expression. When it is temporary it may only appear for a moment when the eyes are suddenly directed in some new direction. The patient will probably come to you complaining of palpitation. This may only be felt from time to time, or it may be continuous. If always present it is easily aggravated by any exertion or excitement. Disagreeable throbbing, especially in the carotid arteries, is often mentioned. The pulse will be found to be frequent—100 or very often 120, or even 130 or 140. If the patient is examined when lying in bed the pulse will be less frequent by 10 or 20 beats a minute. Apart from infective diseases and organic disease of the heart, Graves's disease is the commonest cause of persistent tachycardia. In fact, in all cases, apart from cardiac and infective maladies, in which there is a frequent pulse of 90 or more, it is most important to look carefully for other signs of exophthalmic goitre. Many of these cases are described as examples of paroxysmal or persistent tachycardia and their true nature overlooked. This frequent pulse is such a constant symptom that in 178 of my cases of exophthalmic goitre in which the frequency was recorded, in only 4 was the pulse between 90 and 100, while in 174 it was between 100 and 200. In some of these slight or early cases palpitation may not be complained of, and it is only on examination that the high frequency of the pulse is discovered.

On examination the heart is found to be beating more or less violently and the cardiac impulse can be both seen and felt over a larger area than usual. In these mild cases of the disease there is generally no dilatation or other change in the heart itself. The action of the heart is precisely similar to that we often find in a healthy but nervous young man who presents himself for examination for life assurance or who is undergoing any other mental strain or has just taken violent exercise. If the tachycardia is the only symptom present and the thyroid gland is not enlarged, we may conclude that it is not a case of Graves's disease. For example, I recently saw a lady, aged 52, who had suffered from palpitation for four years. The palpitation came on during an attack of influenza. The pulse was 120 sitting, 104 lying down. The thyroid was normal in size, there were no ocular symptoms, no definite tremor and the weight was increasing. The heart was normal in size and there was no valvular disease. Such a case must be regarded as one of simple post-influenzal tachycardia.

The enlargement of the thyroid gland is generally slight. The gland may be only twice or thrice its normal size, so that the swelling may not even be noticed by the patient at all. It is necessary, therefore, in these cases to make a careful examination of the front of the neck to determine whether there is enlargement or not. It is important while doing this to make the patient swallow a mouthful of water, as in some cases the gland lies rather low down in the neck, and a slight enlargement is more readily detected during the upward movement which accompanies deglutition. The enlargement is uniform and painless. A very notable feature in these cases is the mental condition. The general characters of the mental state in the fully developed disease are well known. In the slight cases also the mental condition may be quite characteristic. There is a condition of irritable weakness, in which a desire to perform many active duties is accompanied by an inability to accomplish them without inducing a disproportionate amount of fatigue. Such patients are anxious to undertake useful work, but are very fussy and nervous in doing it. They feel uncomfortable when in a crowded assembly, and are often obliged to leave early. They are restless, and find it difficult to continue any single occupation for long. There is a remarkable tolerance of cold and sensitiveness to heat. A result, doubtless, of the increased oxidation going on in the tissues. This condition of general nervousness often shows itself in the presence of strangers.

The characteristic fine tremor of the hands is usually present, though it may be necessary to look closely to see it. This tremor was present in 163 of my 180 cases. It was absent in 7, and was not noticed in 10. Weakness of the legs and a feeling as if they would give way in walking may be complained of in these mild cases.

No case should, then, be regarded as one of Graves's disease unless the pulse is 90 or more a minute, and there is either slight exophthalmos, some enlargement of the thyroid, or tremor as well. If two or three of these symptoms are present, the case should be regarded as a mild case of Graves's disease.

There is a special variety of Graves's disease which is generally described as secondary, which may occur in a mild form. As I have already mentioned, in cases of simple goitre of various kinds there is, as a rule, no evidence of hypersecretion, and so the symptoms are purely local. In some cases of goitre, even of some standing, however, the secreting activity becomes increased. This may be so marked that the symptoms of Graves's disease are fully developed, and there is no difficulty in recognizing that we have to deal with a distinct case of secondary Graves's disease. Fourteen of my 180 cases were of this type. In 2 of them the goitre had been present for thirty years, and in others for various periods of from three to twenty-five years before symptoms of hypersecretion developed.

There are, however, cases of goitre in which tachycardia appears alone without other symptoms. These cases have been described by Continental writers as examples of "goitre-heart," so it is well to recognize the existence of these cases, especially in view of any operative treatment, as there is more risk when these signs of cardiac disorder are present than when they are absent altogether. The pathology of this condition is probably the same as

that of Graves's disease, the symptoms being due to excess or change in the character of the thyroidal secretion.

It is also well to remember that if for any reason a patient has been taking large doses of thyroid extract for a long period a condition of thyroidism may be produced in which many of the symptoms of Graves's disease develop—such as tachycardia, tremor, nervousness, sweating, and emaciation.

Time will only permit me to allude very briefly to the treatment of these slight cases of exophthalmic goitre. As in fully developed cases, we must enforce a sufficient amount of mental and bodily rest according to circumstances. A liberal diet, which includes two or three pints of milk, is required to compensate for the increased metabolism. A mild faradic current applied to the neck for two or three hours daily is often most beneficial. A prolonged course of arsenic in small doses, with or without the addition of tincture of convallaria, is also useful in most of the cases. On no account should thyroid extract be given in these cases, as it naturally only aggravates the symptoms.

Remarks

ON
THE NATURE AND TREATMENT
OF

PARENCHYMATOUS GOITRE.

By FRANCIS L. A. GREAVES, F.R.C.S.,

— SURGEON TO THE DERBYSHIRE ROYAL INFIRMARY.

UNDER the term "goitre" several varieties of enlargement of the thyroid gland are embraced, and in classifying them great difficulty is felt at the outset from the fact that the varieties are not very distinct.

Part of the gland may show changes characteristic of one class, while another part may display all the features of a goitre of another class. English pathologists regard parenchymatous goitre as distinct from adenoma of the thyroid, but the German schools do not make this distinction. But there is much to recommend the English classification from the point of view of the practical surgeon.

The normal thyroid gland consists of a vascular fibrous stroma, including in its meshes rounded follicles or acini which either possess a central lumen or are filled entirely with epithelial cells. The acini are lined with a single layer of cubical epithelium without basement membrane, and the lumen may be either clear or filled with colloid material.

PARENCHYMATOUS GOITRE.

In parenchymatous goitre there is glandular proliferation which results in the production of clusters of cells or of gland-like acini lined with epithelium, which may be somewhat irregular and flattened compared with the normal gland. Both varieties may be seen in the same specimen. The cut surface of a fresh goitre shows to the naked eye a reddish or dark brown colour; in parts where many of the acini contain masses of colloid material the section has a translucent honey-like appearance. All the tissue elements in these goitres are increased in amount.

The patient presents a smooth, full neck, reminiscent, when present to a small extent, of Burne-Jones's paintings. This condition is more common in females than in males, and generally commences about the age of puberty. It is at first quite painless, giving rise to no discomfort. The consistency of such a gland is rather soft and has a somewhat elastic feeling on palpation. It is movable on swallowing.

It frequently enlarges during the menstrual period, and the patient sometimes complains of a slight sensation of suffocation at that time. The voice is not altered and no laryngoscopic changes are to be seen. In many of these cases I have found great hypertrophy of the tonsils, and removal of these seems to have some influence in producing

diminution in the size of the gland; possibly this may be due to the improvement of the patient's general condition.

This mild variety of parenchymatous goitre, which is exceedingly common in Derby and Derbyshire, often subsides gradually without treatment as the patient develops. It is quite common for people here to say that they had a Derbyshire neck when they were young. The popular treatment in the female is to apply a string of artificial pearls or a black velvet neck band, and I was recently much interested to read in the *BRITISH MEDICAL JOURNAL* that the Abyssinian treatment of goitre is to tattoo a string of beads round the neck.

Besides the enlargement of the gland at the menstrual period I have seen the same occur during pregnancy, and decrease in size after childbirth.

When the goitre enlarges to a further degree, the swelling is unsightly, the feeling of suffocation becomes more marked, especially in the recumbent posture. There is often associated anaemia, and the case demands treatment.

An inquiry into the residential situation of the patient is made, and the water supply and general hygienic surroundings ascertained. The water should be boiled and flavoured with lemon to make it palatable. Internally a mixture containing iodine and potassium iodide is given, and if there is anaemia, iron and arsenic also. Thyroid extract may be tried, commencing with $\frac{1}{4}$ -grain doses every other day, and gradually increasing it up to 1 grain three times daily. But the effect on the pulse should be most carefully watched. In my experience the result of treatment with thyroid extract has been very disappointing. If no diminution occurs with this treatment after a month's trial it is useless to continue. Locally the red iodide of mercury ointment has seemed to have some effect, the patient spreading it over the enlarged gland, and then sitting in bright sunshine or before a hot fire. It is very difficult not to blister the skin, however, and although good results are reported from India, its effect has not been very convincing in my own practice.

If such cases are watched for some time the swelling, instead of being uniform, becomes asymmetrical. The changes producing the asymmetrical enlargement are briefly as follows: The acini undergo great dilatation with colloid, the lining cubical cells become flattened, the intervening stroma is absorbed, and a small cyst is formed. This degenerative cystic formation generally causes the formation not of a single cyst but multiple small ones. Haemorrhage may take place in these, thus increasing their volume. Another cause of asymmetry is the growth of a definite encapsulated adenoma, which in its turn often becomes cystic. There may be one or many adenomata, and all stages of cystic degeneration of these may be seen in one gland. Again, asymmetrical enlargement is seen in carcinoma, primary or secondary, in sarcoma, and in endothelioma of the gland. Suppuration is yet another cause of asymmetrical enlargement, and is due to breaking down of new growths, especially sarcoma, to suppuration in a pre-existing cyst, either due to auto-infection or to the injudicious introduction of a septic needle. Metastatic pyogenic deposits have been seen in pyaemia and very rarely gummatous and tuberculous granulomata.

If the parenchymatous goitre is of long standing, other degenerative phenomena are common. Fibrous degeneration, with shrinking of the acini and blood vessels and great increase of the fibrous tissue stroma, may be found. This has been observed to lead to myxoedema, or at any rate patients with myxoedema sometimes give a history of having had previously an enlarged thyroid. Impregnation of the fibrous tissue stroma and colloid substance with lime salts is quite common, and true bone is said to have been observed. Colloid degeneration of the stroma itself is sometimes seen; and in such cases the walls of the blood vessels, becoming softened, may give way and a sudden enlargement of the gland due to haemorrhage take place. Amyloid degeneration is occasionally found. The arteries being the chief seat of change, but circumscribed amyloid deposits have been also seen.

Course.

Many goitres, besides the deformity and slight dyspnoea, give rise to no other symptoms.

Dyspnoea, however, is often urgent, and depends on several factors. The gland being tightly bound round the trachea by the deep cervical fascia causes lateral pressure

on the sides of the trachea, producing the "scabbard-shaped" stenosis. If one lobe only is enlarged the anterolateral aspect of the trachea is pressed inwards. It is extremely rare for the pressure to be exerted in an anteroposterior direction, and I have not seen such a case. Another cause for very urgent dyspnoea is enlargement of one or both lobes in a downward direction and impaction behind the sternum. Dyspnoea due to paralysis of the abductor muscles of the larynx by pressure on the recurrent laryngeal nerves I believe I have seen in one case; it was most urgent; aphonia was present at the same time, but the patient was far too cyanosed when I saw her to warrant a laryngoscopic examination; hemithyroidectomy was performed, and she is now well but has paralysis of the right recurrent laryngeal nerve.

Dyspnoea due to penetration of the trachea may be produced by malignant disease or rupture of a suppurating cyst. Softening of the tracheal rings is supposed to occur, but my experience coincides with that of Berry; in one case in which stridor had been so marked that tracheotomy had been performed I was able to show *post mortem* that the tracheal rings were compressed laterally, but no absorption of cartilage had taken place, and they were in no wise softened.

Besides these cases of dyspnoea, acute oedema of the larynx has been seen, more often in malignant disease of the thyroid than in simple, and swelling of the mucous membrane of the trachea itself may also occur. If there is inflammation of the thyroid gland itself, there may be extension into the lumen of the trachea; but more often the swelling of the tracheal lining is only part of a general catarrhal condition of the air passages due to cold, influenza, etc., and only becomes noticeable from the lumen of the trachea being narrowed by a thyroid tumour. A patient with a parenchymatous goitre often says there is no dyspnoea unless he has a cold, and then it may be very urgent indeed.

Difficulty in swallowing is not a common symptom, but in one case under my care it was the only one. Several cases of intense dysphagia due to goitre have been described, but were mostly due to extensions of the thyroid behind the oesophagus and pharynx.

Pressure on the cardiac nerves and on the large blood vessels has been described, especially in the intrathoracic goitres. Tachycardia and irregular heart-beat and some oedema of the head and face, especially the eyelids, have resulted from such goitres.

The symptoms hitherto detailed have been mechanical or pressure symptoms. If the thyroid gland is removed or atrophies, the train of symptoms known as myxoedema results. Now, when all its elements undergo hypertrophy, are there no physiological symptoms produced other than pressure symptoms?

In order to answer the question properly it is necessary to consider what we know of the secretion of the thyroid gland, which is so necessary to the human body. The thyroid is a ductless gland and the colloid substance which fills its acini is its internal secretion or contains it.

The colloid is formed from the granules which can be seen in the cells of the acinus; these granules discharge themselves into the lumen of the acinus, where the colloid collects until a separation of the cells is produced by pressure and the colloid is emptied into the lymphatic spaces. From these spaces the lymphatic vessels convey the secretion into the blood stream by the thoracic duct, etc. According to some observers the colloid is directly absorbed also by the capillary blood vessels. Chemical examination of the gland shows that it contains two products, a nucleo-albumen and the colloid substance. This latter substance is a compound proteid containing iodine, the percentage varying, but forming about 3 per cent. of the dried gland. The colloid is not a nucleo-proteid, as no albumin is yielded by gastric digestion. When the colloid is subjected to digestion, only those substances which contain iodine possess active properties. The active substance, called iodothyronin, produces the same effect on the metabolism of the body as the gland substance itself. It is a brown amorphous substance, almost insoluble in water, but readily soluble in weak alkalis. It contains phosphorus and about 10 per cent. of iodine and gives no proteid reaction.

The nerve supply of the gland is derived from the vagal nerves and the sympathetic. Pembrey did

not observe any structural changes in the cells as the result of section or stimulation of these nerves or of the vago-sympathetic trunk, and states that the evidence is all against nervous control of the glandular tissue of the thyroid. Edmunds, experimenting with dogs, comes to much the same conclusion. He says:

The paralyzing operation does produce some effect both clinical and pathological, but not a great effect; and it must be inferred that the secretion of the thyroid gland is due mainly to a chemical stimulus acting directly on the secreting cells, or on the nerve endings distributed to them, or through fibres which pass along the blood vessels with the sympathetic fibres.

The present belief appears to be that the thyroid gland is in a constant state of slight activity, which is increased under certain conditions. The stimuli which affect the gland appear to be chemical and arrive by way of the blood stream. Proteid feeding has been thought to produce hyperactivity, in fowls at any rate; but Forsyth's controverts this view, which was put forward by Chalmers Watson in 1904. Fordyce² (Edinburgh) has made some interesting observations as to the result of feeding rats with milk only or bread and milk. Increase of colloid was found in the pure milk-fed rats. The fact that symptoms of hyperthyroidism do not occur in all goitres that are hypertrophied cannot be due to diminution of the lymphatic spaces by increased amount of fibrous tissue present and the consequent contraction that would follow. In those cases of parenchymatous goitre in which the colloid is so abnormally increased in amount that the freshly cut surface has a honeylike appearance, one would have expected that the colloid would readily have been absorbed by the lymphatics, which are also increased in number. But as a rule we find no symptoms of hyperthyroidism in such cases, so it is probable that the amount of colloid material is no indication of the amount of active internal secretion, and this enormous increase of colloid is a sign of gland degeneration rather than of increased cell activity.

Exophthalmic Symptoms.

But there are occasionally seen cases—the *formes frustes* of the French—which present clinically in the goitre, and also microscopically, typical parenchymatous glands, and which have also marked general symptoms, especially tachycardia and tremors. It has been attempted to prove that those cases of Graves's disease which have apparently benefited by hemisection came under this category. With this view I disagree, and will relate two cases in justification.

CASE I.

Mrs. C. W. came to the out-patient department of the Derbyshire Royal Infirmary in June, 1905. She had had no children, and gave a history of poor general health. The thyroid was enlarged, especially on the right, where it extended from the right sterno-clavicular joint to the submaxillary region. There was some hoarseness and difficulty in swallowing, but tachycardia, palpitation, and tremors of the hands, faintness and giddiness were the chief symptoms. There was no exophthalmos, and von Graefe's sign was absent. The heart was enlarged, and the pulse-rate 136. There was impaired movement of the right vocal cord.

She was admitted under Dr. Thornton, and as with rest, etc., no improvement followed, I saw the case with him and advised operation. A very large right lobe was removed, and part of the isthmus, the pathological report on which is as follows: "This is a typically parenchymatous goitre. The cells of the thyroid are of different sizes, and their lumen is full of colloid substance. There is no small-celled infiltration or epithelial proliferation."

The wound healed by first intention, and she was discharged with a pulse-rate of 80, palpitation and tremor still present; the right vocal cord was still not freely mobile, and the dysphagia had not quite disappeared. For two months she was kept under observation and the dysphagia became more marked, a swelling in the middle line running up to the thyro-hyoid membrane appeared, and in September, 1906, I removed a lobulated tumour undergoing cystic degeneration. Since then there has been no dysphagia, her general condition is better, and the tachycardia only present on any mental excitement.

This was one of the *formes frustes*, which benefited to a considerable extent by operation.

CASE II.

E. W. had been a domestic servant, but had done no work for two years owing to Graves's disease. The symptoms were increasing, swelling of the thyroid gland, pulsation and thrill, very marked exophthalmos, von Graefe's sign, Stellwag's sign, tremors of hands, jerky movements, tachycardia, hot flashes, and wasting diarrhoea. The pulse-rate was 140 when seen at

the out-patient department. She attended for four months and did not improve; she was then admitted under Dr. Thornton, who treated her for six weeks.

As she was getting weaker rather rapidly he asked me to operate. I used local anesthesia, allowing the patient to smell a Skinner's mask flavoured with chloroform. The whole right lobe was removed and the left superior thyroid artery ligatured. The microscopical report was: "This is a thyroid gland showing the characteristic cell proliferation found in exophthalmic goitre."

Although rather excitable for twenty-four hours after the operation, she made a rapid recovery and has now been at work for nearly twelve months. Her pulse-rate is about 80 and all her other symptoms have practically disappeared except the exophthalmos, which I think is much the same, but the patient declares is better.

I think it is not necessary to say more to prove that this was a true case of Graves's disease which had benefited by operation. I have had the opportunity of seeing with Dr. Thornton several other cases of *formes frustes* in which the symptoms have not been so well marked, but the occurrence of hyperthyroidism as the immediate result of surgical interference may be touched upon in this connexion.

In one of my own cases, a girl with a large parenchymatous goitre and a thick short isthmus, there were symptoms of hyperthyroidism, restlessness, rapid pulse (140), flushed face and slight elevation of temperature for forty-eight hours after operation. The wound, which was drained as usual for twenty-four hours, was perfectly aseptic throughout. After forty-eight hours the pulse-rate came down to normal, and the patient was discharged cured in a week. In a case under one of my colleagues I saw the same condition. In the case of a young man, operated on by Mr. C. H. Hough at the Derbyshire Royal Infirmary, the heart, a few hours after operation, became very rapid and irregular, great restlessness and sweating was noticed, together with tremors of the hands. The patient died in thirty-six hours from the time of operation. All these cases were both clinically and microscopically parenchymatous goitres. In all the internal secretion must have been distributed to the body in excess at the time of the operation. This must have been due to the manipulation of the gland forcing the internal secretion into the lymphatic spaces, although, as far as possible, this is reduced to a minimum by retracting the surrounding structures away from the gland and touching it as little as possible with the hand. Another cause must be escape of the internal secretion directly into the wound when the isthmus is divided. To limit this as far as may be, the isthmus is, when possible, crushed in a clamp, ligatured and divided, and the wound is rapidly washed out with hot normal saline to limit the amount of internal secretion left in it. If the isthmus is thick and fleshy, the application of the crushing clamp itself must force an undue amount of internal secretion into the surrounding lymphatic spaces. I have noticed that post-operative hyperthyroidism has not occurred in patients whose thyroids contained enormously dilated acini, but rather in those firm, fleshy glands in which the acini are only moderately distended with colloid; these patients are usually young people—that is to say, post-operative hyperthyroidism is most likely to occur in the actively secreting glands of moderate size, and not in the parenchymatous glands which are enormous and whose contained colloid is more a sign of degeneration than active secretion. I know that certain patients with cystic goitre, when the cyst has ruptured during operation, have exhibited signs of post-operative hyperthyroidism, but as a rule no such manifestation occurs. Enough has been said to warrant the belief that the colloid is the vehicle which contains the active internal secretion, and this may be present in a larger or smaller amount, but the quantity of colloid substance present is no indication of its physiological value.

THE OPERATION.

A sandbag is placed under the neck. The anaesthetist is shut off from the operation area behind a sterilized sheet held over two upright iron supports. The sheet is continued over the body, and there is a slit in it which comes over the goitre, the edges of which can be clipped to the skin incision. In parenchymatous goitre the incision should be transverse. The resulting scar is excellent, and can be concealed by a strip of velvet or a necklace. None of my patients have been dissatisfied with the

cosmetic result. The anterior borders of the sternomastoids should be well defined to permit of easy retraction. The infrahyoid muscles and the layer of fascia covering them are divided close to the hyoid bone and dissected off the front of the gland. In this way the nerve supply is not interfered with, and the line of suture at the end of the operation does not coincide with the skin incision. All bleeding is now carefully stopped. The upper pole of the lobe to be removed is cleared first, and the superior thyroid artery and vein clamped between two pairs of forceps and divided, and then tied off in one ligature. In some of my earlier cases I tied the superior thyroid vessels with an aneurysm needle and then divided them. But since the ligature with which the artery was tied once slipped off when I was dividing it, I have given up the aneurysm needle. The next step is to tie the middle thyroid vein, and in doing so to free the outer border of the gland. Then the upper border of the isthmus and the pyramidal lobe is cleared, and then the lower border of the isthmus is defined. The inferior thyroid vein is tied at this stage, and the thyroidea ima if present. The isthmus having been defined is crushed up in a clamp, one blade of which is carefully passed between the trachea and isthmus. The crushed portion is easily tied and divided; if any colloid escapes at this time into the wound it is washed out at once with hot sterile saline solution.

The half gland can now be held downwards and forward, and the attachment is the inferior lateral ligament and inferior thyroid artery. This is the most anxious part of the operation. The artery is in such close relationship to the recurrent laryngeal nerve that several methods have been adopted to protect the latter. Careful isolation of the nerve has been performed, but in one case in which I did this the patient suffered from recurrent laryngeal palsy which did not clear up for several weeks after operation. Another method is to cut obliquely into the tissue of the gland itself and to pick up the points of the inferior thyroid artery inside the capsule. In this way the nerve is not seen and the bleeding arrested easily, but unless the assistant is very careful not to allow the ends of his forceps do more than seize each bleeding point, I conceive it possible that the nerve might be nipped up and included in a ligature just the same. I now prefer to hold the gland well out of the wound, and, cutting absolutely on to the capsule itself, pick up the branches of the artery just as they penetrate the capsule. By this means I often see the nerve, but do not disturb it with instruments, and so have never had any traumatic neuritis. The gland being now free is lifted out of the wound, a hole is made at the lower end of the musculo-fascial sheet, a drainage tube inserted, and the muscles and fascia sutured where divided, the sandbag under the neck being removed at this point and the head raised by the anaesthetist. The skin is now sutured with interrupted finest silk-worm gut, the glass drainage tube is left projecting, and the wound carefully dressed with sterile gauze, wool, and bandage. The patient is propped upright in bed, with bed-rest and pillows carefully supporting the head. The wound is dressed in twenty-four hours and the tube removed. The patient is allowed out of bed on the fourth day. Stitches are removed on the sixth or seventh, and a collodion and gauze dressing applied.

Single adenomata may often be shelled out easily, and sometimes multiple ones also by cutting into the gland capsule and dividing the gland substance until the adenoma is reached. But it often happens, if many adenoma are present, that a hemi-extirpation is the only practicable operation possible.

The immediate results of thyroid operations are excellent; healing by first intention is practically always obtained. Amongst nearly forty cases that I have had in hospital and private practice, there has been one case of suppurative, and that occurred after the wound had apparently healed, being due to a spreading infection from the site of the tube.

THE late Mr. J. A. D. Shipley, solicitor, of Newcastle-on-Tyne, has directed that after the payment of certain legacies his residuary estate, estimated at £100,000, should be divided amongst various local charities, including the Royal Victoria Infirmary and other medical institutions.

PULMONARY TUBERCULOSIS IN CHILDREN.

By MARY HAMILTON WILLIAMS, M.B.,
B.S. LOND., D.P.H. CAMB.,

SENIOR MEDICAL INSPECTOR OF SCHOOLS, WORCESTERSHIRE.

I hold the view that phthisis is one of the most common diseases of childhood, and that among those who die of it at the ages when it causes the highest mortality, the majority have contracted and suffered from the disease in childhood—that is, during the first fifteen years of life.

I am aware that eminent men have frequently and recently expressed opposite views. I know that to venture to express my views is to be called an alarmist; but I consider that in order to abolish the high phthisis death-rate in early adult life it is absolutely essential to admit that the disease has existed in a recognizable condition for years, and during these years, has been in the highest degree amenable to treatment.

Death and Morbidity Statistics.

Various figures are given as to the number of persons found at autopsies to have tuberculous lesions in the lungs.¹

Death Statistics, London, 1905.

Estimates vary from 27 to 75 per cent. Let nearly the lowest—30 per cent.—be taken.² In 1905 the phthisis death-rate in London was 0.142 per cent. of persons living.

(a) Therefore for every 0.142 persons dying of phthisis, 30 suffer from it. This ratio probably holds also for children, and if not, it is too low. The number of children dying of phthisis in London in 1905 at ages 5 to 15 was 176.³

(b) Therefore the estimated number of children dying of phthisis in London in 1905 at ages 5 to 15 was 92.

(c) From (a) and (b) we find that the number suffering from phthisis corresponding to the 142 dying of it = $30 \times \frac{142}{0.142} = 30,000$.

(d) Number of children aged 5 to 13 in London = 694,774. From (c) and (d) we find that among 694,774 children the number suffering from phthisis = 30,000.

Results of Medical Inspection, London, 1905.

The number of children on the rolls in the London schools examined was 165,915. Therefore the probable number suffering from phthisis among these was $\frac{30,000}{694,774} \times 165,915$

= $[\log. 30,000 + \log. 165,915 - \log. 694,774] = 7.164$ —that is, it is probable there were, roughly, 7,164 children suffering from phthisis in the schools examined, and from (b) and

(c) the number of deaths from phthisis = $\frac{142}{694,774} \times 165,915$

= 34 (approximately).

In the report of this year, 1905, there is no record of the finding of any cases of phthisis, though we have seen that it is probable some 7,000 children were suffering from it in the schools examined.

Death Statistics, London, 1906.

The alteration in percentage death-rate from phthisis in London between 1905 and 1906 was 0.002.⁴ The number of deaths from phthisis between 5 and 15 was (74 + 82) 156, instead of 176 in 1905.⁵ Considering the ages 5 to 13, this number would be 123. Hence there was no material alteration in the number of deaths.

Results of Medical Inspection, London, 1906.

In the schools examined this year there were on the rolls 208,374 children, and there was again no record of cases of phthisis.⁶

In an examination undertaken in a few schools with special reference to phthisis, a few cases were recorded, reaching the percentage of 0.5.⁷

But if 123, according to the Medical Officer of 11¹, for London's returns for 1906, died of phthisis among the 694,774 children in London, there must have been, roughly, 36 school children who died of it, and some 7,605 children suffering from it, among the schools examined.

These calculations are based on nearly the lowest set of figures obtainable. We can only suppose that these 7,000 children were all suffering from it in a so-called latent stage; or, in plain language, in a stage not sufficiently advanced for those particular observers to detect it.

We are thus met at the outset with a startling fact. Some 200,000 children were on the rolls in the schools examined, and were inspected by certain members of the staff of twenty-five doctors. It is true that the examinations were not as systematic as is demanded now, but a fair number were cases of delicate children picked out by the teacher, or the doctor, for ill health,

and hence were more likely to have been suffering from phthisis than if the work had been purely routine—that is, only among non-selected cases. It has been contended that there were no cases of phthisis in those schools because they had been drafted into the "invalid schools." There is no record in 1905 of such a drafting in the report of those invalid schools; and if they had been so drafted there would have been some mention of the examinations in the ordinary schools, when the fact that they suffered from phthisis was detected. According to the figures I have just given it is obvious that there must have been children examined in every stage of phthisis, except the late stages, and that the examining doctors failed to detect the disease. What happened in London is sure to have happened elsewhere.

In a leader on the subject in the *BRITISH MEDICAL JOURNAL* of February 9th, 1907, is the following passage:

It is a curious fact that no cases of pulmonary tuberculosis, or of predisposition to pulmonary tuberculosis, are noted in the London elementary schools. In France a large number of children, ranging from 2 years to the end of school age, are received into sanatoriums for children, either predisposed to or suffering acutely from tuberculosis. How is it, then, that in England, where such a large number of deaths occur from phthisis, no notice is taken of the disease until after school age? It is in the highest degree improbable that the true condition here differs so essentially from that existing in France, and a careful inquiry into the matter would be of the very greatest interest.

In 1906⁸ the presence of sixteen phthisical children is reported in the invalid schools.⁹

Dr. Newsholme quotes the following figures as obtained by various observers to indicate the amount of phthisis in our school children.¹⁰

	Number of Children Examined.	Percentage Phthisis.
Drs. Lecky and Horton (Brighton)	806	0.37
Dr. Mackenzie (Edinburgh)	600	2.3
C. O. S. (Edinburgh)	1,318	1.4
Professor Hay (Aberdeen)	600	0.5

Dr. Greenwood, in Blackburn, among 1,023 children, gives 6.7 per cent.¹¹

The late Dr. Grancher, of Paris, in a most careful paper on the subject, found the percentage among 4,226 children to be 15.¹²

Dr. Hyslop Thomson reports from Glasgow that among 779 patients seen for chest complaints in hospital there were 43 children under 16 with phthisis.

Proportion of Tuberculosis Found Post Mortem in Children Dying of Various Diseases.

With tuberculous lesions in any organ, Harbitz¹³ of Christiania, among children under 15, found 42.5 per cent.

Comby,¹⁴ of Paris, gives for children aged 2 to 10, the percentage 67, and for the ages 10 to 16 the percentage 64.

Nägeli,¹⁵ of Zurich, has furnished a series of figures, which are frequently quoted. For children under 13 his series gives a percentage of 17. But he explains that this figure is much too low, as for various administrative reasons children with tuberculosis are commonly refused admission to the hospital at which the necropsies were made.

The most complete table I have been able to obtain is that drawn up by Hamburger and Sluka,¹⁶ who give their own results and also the figures obtained by other observers. A most careful bibliography is given at the end of the paper.

Author.	Age of Children.	Number of Necropsies.	Number of Tuberculous.	Tuberculous per cent.
Müller	0-15	500	209	46
Baginsky	?	806	144	18
Orth	0-15	418	47	11
Nägeli	0-15	88	15	17
Burchhardt	0-15	130	72	43
Ancell	0-15	154	42	28
Hamburger and Sluka	0-14	451	100	40

¹ Read in part before the Worcestershire and Herefordshire Branch of the British Medical Association, and in part before the Association of Registered Medical Women, London.

Further information is given for special ages (1) by Müller,¹¹ (2) by the authors:

Age.	Number Found Tuberculous.	
	1. Per cent.	Per cent.
5-6	50	60
7-10	40	64
11-14	75	77

Hamburger and Sluka¹² also state that among 100 children dying in a hospital in Vienna, of various diseases, 40 had tuberculosis, recognizable by macroscopic examination. This number would, of course, be much higher if microscopic examination had been made. These Austrian figures probably fairly represent English ones—for it has been shown that the death-rate in London was 142 per million, while for Austria in 1901 it was 144.¹³

Ganghofner²⁰ has given figures for 1,800 autopsies on children who during life had not been recognized as suffering from tuberculosis:

271 deaths, ages 4-6, percentage with tubercle = 26.9.
123 deaths, ages 6-8, percentage with tubercle = 26.8.

It is very difficult to obtain figures as to the numbers in whom tubercle was found in the lungs, and we can only consider approximate figures.

Hamburger²¹ gives 63 cases of pulmonary tuberculosis in 160 cases of tuberculosis. Nägeli states that of his cases nine-fifteenths showed lesions in the lungs.

Dr. Newsholme²² estimates that among deaths due to tuberculosis the proportion due to phthisis is 69.5 per cent. Professor Osler²³ quotes Müller to the effect that, in children, the lungs are involved in 92 per cent. of tuberculous infection. This was the percentage at autopsies at the Munich Pathological Institute.

We may note here that Baginsky, in 933 autopsies in children with tuberculosis, could find no case in which the lungs only were infected, indicating, that primary lung tuberculosis is rare in children.²⁴

We thus see that statistics from autopsies support the contention that tuberculosis of the lungs is a common disease in children.

There is a serious discrepancy between the figures for tubercle of the lungs in the dead, and the highest figure we have been able to find for recorded English observations in the living, that given by Dr. Greenwood, 6.7 per cent. Apparently observers class the undiscovered cases as "latent," but I can hardly believe we are willing to admit we cannot do something better at diagnosis than this.

PROBABLE AGE OF INFECTION.

Professor Behring has said: "The bacilli which gain access to the alimentary tract in infancy constitute the important etiological factor in the production of the tuberculous infection which leads to consumption."²⁵ With this statement I agree, and I believe that the great majority of the cases of consumption, especially those who die between 15 and 35, were infected in early childhood, and have had tuberculous lesions in the lungs for periods varying from five to twenty years.

In a recent most able paper read by Dr. Newsholme before the Epidemiological Society, he altogether differs from Professor Behring, and in support of his view he adduces statistics relating to the ratio between deaths from phthisis and the infantile mortality in various countries.

His argument is that tuberculous infection from cow's milk must take place mainly in those districts or countries where the greatest amount of artificial feeding takes place. This appears reasonable, except in so far as we need not limit the period of probable infection to the first year of life; I would extend it in a lessening rate through the years of childhood. The best gauge of the amount of artificial feeding is admittedly the infantile mortality rate. So far, in the main, I agree. But then, Dr. Newsholme continues, if the liability to the infection and the infant mortality are both greatest under the same circumstances—that is, when there is much artificial feeding—then the infant mortality-rate and the phthisis-

rate should show a definite correspondence in the various towns and countries. But he states "there is an utter absence of correspondence," and in support of this statement he gives statistics. Hence he deduces that Professor Behring's theory of the frequency of infantile tuberculous infection is in the highest degree improbable.

I disagree entirely with this deduction. If the infantile mortality is high, that means that a large number of the children infected with tuberculosis by cow's milk die in early infancy. Probably the majority of those seriously infected die. These deaths will be certified as due to every disease of which babies may die, and will not materially raise the phthisis-rate.

Surely it is obvious that, according to this view, there will be left, in such areas, a much smaller proportion of children than usual with tuberculous infection, and hence a high infantile mortality will produce a low phthisis death-rate. And this view is confirmed by the actual statistics given by Dr. Newsholme.²⁶

	Phthisis-Rate.	Infantile Mortality-Rate.
England and Wales	1.23	139
Belgium	1.25	147
Scotland	1.53	123
Ireland	2.15	99
Norway	2.02	86
Sweden	2.92	96

Dr. Newsholme also argues against this view (that of frequent tubercle of the lungs in childhood), because the phthisis death rate has declined greatly in the last forty years, and he states there has been no corresponding improvement in the condition of the dairies. This is not a very convincing argument; many of us think there is a very appreciable increase in the trouble taken to obtain germ free milk. We still use milk which is a disgrace to civilization—but we used to use milk which was a disgrace to barbarism. We take a certain amount of care now in regard to the milk after it has left the hands of the milkers, and we sometimes endeavour to destroy the tubercle bacilli, though we still do little to prevent their obtaining entrance to the milk.

Now let us see whether my view finds support, or the reverse, from other statistics given by Dr. Newsholme²⁷—namely, the varying death-rates from phthisis for the two sexes at different age periods.

RATIO OF MALE TO FEMALE DEATH-RATE AT EACH AGE PERIOD. That of Females at each Age Period = 100.

Age Period.	Urban Counties.	Rural Counties.
0	117	117
5		46
15	107	92
25	134	121
35	160	121
45	224	166
55	241	163
65	223	164
All ages	150	116

The main fact is that in childhood, from 5 years to 15 in the towns and somewhat longer in the country, there is some factor which keeps the male phthisis death-rate below the female; and conversely, as the boy reaches manhood, there is some factor which causes the male phthisis death-rate to be higher than the female.

In early childhood, as babies, boys and girls are treated very much alike. As children there is a distinct difference. From 5 to 15 is the boy's "good time." His comfort is considered before his sister's, and he himself succeeds in assisting to maintain this desirable state of things. He is regarded as needing the best food, and out of school hours he is out of doors playing. The girl is all too frequently

indoors nursing the baby or helping in the house. If the boy and girl are both infected with pulmonary tuberculosis, which has the best chance of keeping in good health? The boy undoubtedly. Hence during boyhood the male phthisis death-rate will be lower than the female.

In the country this state of things will probably continue in the boy's favour longer than in the town, for, if the boy begin work at 12 or 13, in the country it will probably be out-of-door work. In the towns circumstances will be less in his favour, and this fact is borne out by the phthisis death-rate.

As the children reach adult life the factors in favour of the boy cease to operate: the male is the breadwinner, and the stress of work falls on him. Suppose, again, both the boy and girl infected; throughout his boyhood circumstances have been favourable to the boy, he has held his own in the fight against the bacilli. But once let such a boy be exposed to the stress of work, with the many influences so aptly described by Dr. Newsholme as "urbanization," and the apparently latent infection will take effect; the young man will succumb. No such immense change in circumstances takes place as a girl reaches womanhood, and hence the phthisis death-rate among the young women is then less than among the males.

The second factor operating to maintain this inequality is the larger number among the girls who have succumbed to tuberculous infection in childhood. A smaller number of infected are left alive in early adult life among the females than among the males.

Urbanization.

The discrepancy between the phthisis death-rate of men and women is much higher in the towns, and this is what one would expect, for the urbanization would have more effect on the men than women. But as the effects of urbanization would take some considerable time to act detrimentally, it is reasonable to consider that the effect would be greatest in later years, and hence would produce its chief effect on the death-rates at a period when our two previous factors have nearly ceased to act.

Methods of Tuberculous Infection.

A few years ago we believed that in infant infection was by the alimentary tract, and that inhalation infection was unimportant. We believed that children suffered from tuberculosis mainly in the alimentary, glandular, and osseous symptoms. In regard to adults, the idea was that infection was mainly by inhalation, and that the phthisis, which causes the appalling death-rates from 15 onwards, was a disease originating in the lungs. So far as experimental evidence in animals went, there was nothing directly to contradict these views.

The most important points in recent work on this subject were very clearly recorded, with most careful references, by Sir William Whitla in the *BRITISH MEDICAL JOURNAL* of July 11th, 1908. He considers that the following points are proved:

1. That the bovine type of bacilli is found in human tubercle, the great majority occurring in intestinal or mesenteric disease.
2. That the bacilli can pass through the mesenteric glands without leaving any trace, thus disproving the widely accepted belief that, if no abdominal lesions are found in cases of phthisis, it is proof that infection was not via the alimentary tract.

Hence we cannot accept figures, such as Dr. Still's, based on the older theory.

3. "That in the immense majority of cases tuberculosis is not contracted by inhalation, but by the ingestion of bacilli or bacilliferous products by way of the intestinal mucosa." (Calmette.)

No one who has read the paper alluded to can doubt that, very shortly, this last contention will be an axiom.

The common route of infection appears to be the intestinal mucosa—not the stomach—by way of the lacteals or lymphatics to the mesenteric glands, thence (either free or in phagocytes) into the thoracic duct, to the venous circulation, and thence to the lungs. The deep cervical glands share in this infection, and this is of importance as explaining some of the cases of cervical adenitis in which no local lesion can be detected, and as suggesting that in many cases, when there are tuberculous glands in the neck, their infection is a later event than that of the lungs, and has occurred by the same route.

As bearing on this question as to when the disease is acquired, I may quote the opinion of the Royal Commission of 1894, that: "No doubt the largest part of the tuberculosis which man obtains through his food is by means of milk containing tuberculous matter." And Dr. S. Martin says "that the milk of cows with tubercle of the udder preserves a virulence which can only be described as extraordinary."

The work reported by Sir William Whitla indicates that the chief track of tubercle infection is by the alimentary system. The commissioners insist that milk is the most common article of infected food. Undoubtedly milk is more used as a food by children than by adults, and hence this line of reasoning leads back to my original contention—that the greater part of the phthisis existing in adults starts in young children. Further, von Behring, and also more recent observers, have shown that the greatest permeability of the intestinal mucosa exists in early childhood, and, hence, that it is at this period that tuberculous infection of the lung is most liable to take place.

It is no doubt probable that a certain amount of infective material is first inhaled into the mouth and pharynx and then swallowed. This source of infection is open to children and adults alike, with again, however, a reservation in favour of its more common action in childhood, for the reason that it is in childhood that we find the greatest amount of mouth breathing, and in early childhood that we find the greatest tendency to place in the mouth articles other than food which may have become infected with tuberculous dust.

Dr. Newsholme puts forward the view that segregation of consumptives, particularly of the advanced cases, has been the most important item in the various changes which have brought about a decrease in the death-rate from phthisis.

I venture to suggest another change which has worked in the same direction—namely, since the beginning of compulsory education, the taking of the children out of their homes, for five hours a day, into the schools. The homes are the places where the most infection must exist for they are the places where the last stages of a consumptive's life are passed. In school there are rarely cases of advanced consumption.

But, though the present conditions are an improvement much may still be done in the same direction. There are phthisical children in school and phthisical teachers, and whenever these have coughs they may be a source of danger. Dr. Tatham has found a specially high phthisis-rate among teachers. Heyman²⁸ has shown that in coughing tubercle bacilli are given off, and were collected by him on Petri dishes in 70 per cent. of the experiments. Cadéac²⁹ has shown that the bacilli contained in these "droplets" of phthisis sputum are highly virulent. And, though we may not consider there is much danger of their being inhaled directly into the lungs, yet it is undoubtedly possible that the other method of infection mentioned may occur. Hence it is important that all phthisical children who cough in the day time should be excluded from school. In Denmark no teacher is admitted to the elementary schools without a thorough examination to exclude phthisis, and this is an excellent example for us.

Dr. Bulstrode, in his *Report on Sanatoria*, states that there is one subject on which opinion and evidence are alike—namely, the overwhelming importance of the early diagnosis of the disease, and he quotes Dr. Latham, "That the early diagnosis of pulmonary consumption is a question of supreme importance, perhaps the most important which the physician has to face." Again and again the point is urged that the patients in the sanatoria die because they are sent too late. Hence we are brought back to the importance of the question as to what extent phthisis exists in children.

I am aware that there is a certain number of physicians who say that they will not admit any case to be phthisis until and unless they find bacilli. I have so little sympathy with such a death-dealing view that I can only quote the words of a man whose authority most will acknowledge. Professor Grancher said:

To wait for the presence of tubercle bacilli—that is to say, to wait for the presence of cavities in the lung—is to do an immense injury to the patient, to render incurable or very difficult of cure a tuberculous infection which would have been curable in an earlier stage.

I well remember the two cases, both of close personal friends, which impressed this view upon myself. In the one case we hunted twenty-one times for the bacilli, over a period of two years, before we found them, and then the disease had advanced so far it required years to arrest it; and in the other case we examined twenty-seven specimens, and only demonstrated the disease to an unbelieving family doctor at a stage when it had become hopeless.

There is a widespread belief concerning phthisis which is extremely mischievous—that it is a disease which tends to a fatal termination in a period of less than five years. It is an extremely chronic disease, frequently starting and recognizable in childhood, and tending in the majority of cases to recovery.

Dr. Newscholme, to a certain extent, admits this view, for he says that "in notified cases of phthisis the infection very commonly dates back ten to twenty or even more years." If this statement only applies to the elderly among his phthisis cases, it has no bearing on my point. But if he admits the same statement for cases which are notified at ages of 20 to 30, then it would point to the infection having occurred in childhood.

So far I have tried to consider how far evidence, from widely different sources, supports the view I have put before you. Now, only shortly, I venture to lay before you my own experience on the subject. I started examining school children with two ideas on this subject:

1. That most authorities reported that phthisis is very rare among school children, but did not produce any statistics by men whom I could ascertain to have had special experience in diagnosing the disease in adults.

2. That over and over again while living abroad at phthisis stations, patients used to come to me, too late for cure, stating that they had been under their own doctor for years, and that they had started abroad directly he admitted that they had phthisis.

Gradually it began to dawn on me that there was some connexion between these two ideas. Then came the London statistics, a record of work in London among children, which contained no mention of cases of early phthisis, while the mortality returns showed that they must exist in large numbers. I began to consider whether the statements as to the infrequency of phthisis among school children was due, not to its rarity, but to the rarity of doctors who diagnose it.

When we want an opinion on a case of eye disease we consult an oculist. So with various other specialities, and I believe that the diagnosis of early phthisis is just as specialized a work. The cases of early phthisis do not commonly attend the hospitals complaining of lung symptoms, but of a hundred other trivial ailments. The temporary weakness is treated and the lungs are not examined. Hence students leave hospital with an idea of phthisis gathered from the advanced cases in the wards. Naturally we fail to detect cases early, and say we are not sure until we find bacilli.

The figures I have obtained from the children I have examined are, I believe, still too low (see table).

The most valuable figure I consider to be the percentage for the routine cases, town and country—namely, 14.3. The figure for all cases is somewhat higher, namely, 15.4 per cent., and for the selected cases is naturally still higher, namely, 17.9 per cent. In many cases the numbers dealt with are so low as to render the results almost valueless. My figure for all cases, 15.4 per cent., is almost the same as that given by Dr. Grancher.

I am told that some of my cases of phthisis are chronic bronchitis. Professor Osler says: "The frequency of bronchitis prior to recognized lung tubercle cannot be regarded as causative, rather is it symptomatic of existing tuberculosis."¹⁰ I think one difficulty has arisen from the fact that so commonly, bronchitis is a symptom, and yet our textbooks classify it as a disease. I have studied four textbooks on this subject recently, and so far as the point is alluded to at all, it is evident that bronchitis is used to indicate the pathological condition, quite apart from the etiology; the result is that the bronchitis, which is a mere symptom of phthisis, is spoken of as if it were the main disease.

I believe that a chronic non-tuberculous bronchitis is rare between the ages of 5 and 50, unless due to heart disease, Bright's disease, or some other definite pathological entity, and is extremely rare in comparison with phthisis. Dr. Sutherland, in his recent book on *Treatment*

Table showing Results of Examination of Children in Town and Country Schools.

Routine means that the children were taken as they chanced to occur at the given age. *Selected* means that they were those picked out for some sign of ill-health, either by the teacher or myself. This group included many cases picked out only for defective eyesight, vermin, etc.

Routine or Selected.	Sex.	Age Period.	Number Examined.	Number with Phthisis.	Percentage Phthisis.	Town or Country.

of Diseases in Children, does not give a chapter to "chronic bronchitis"; apparently he agrees that it is a disease of the aged. He regards an intermittent bronchitis as a common complication of fibroid phthisis; he speaks of the chronic bronchitis of young children due to rickets, but the usual chapter on chronic non-tuberculous bronchitis is absent.

A child with tuberculous infection in the lungs is by no means necessarily what people mean by "consumptive." In the majority of cases I believe the disease tends naturally to cure, and that, when this is not so, it is on account of one of the following reasons:

1. That the child started life with a hereditary predisposition to the disease, which must be counteracted by special treatment.
2. That the child has been subjected, or is continually being subjected, to so severe an infection that its vital forces are beaten at the outset.
3. That the circumstances of its life are unfavourable.

These three possibilities render it imperative that we should find out which children are already infected, in order that we may counteract any hereditary tendency and alter any adverse circumstances.

Phthisis is not a disease which requires combating chiefly on account of its fatal tendencies, but because it is a disease creating our army of "ineffectives," the people

who are prevented by chronic ill-health from doing effective work. Again, it is a disease to be fought because so many of our children with the best brains are attacked by it. If ever a teacher says to me that such and such a boy is the sharpest in the school, I always notice the lungs with extra care.

Early Symptoms and Signs.

The following remarks do not refer to cases in an advanced stage, children definitely ill, nor need I allude to the classical types of the tuberculous.

Night sweating is a symptom concerning which one of my colleagues has no faith. He says that they all say they sweat. That seems to me only saying that "all men are liars," and needs qualification. There are certain distinctions to be made:

1. If the sweating has existed all the child's life, it is probable the original cause was rickets. If it has started recently, or has existed in infancy, stopped, and started again, it has weight.
2. If the sweating is not constant, but occurs from time to time, whenever the child catches cold (of course excluding the results of hot drinks at night).
3. The sweating must be on the forehead or round the neck. It may be elsewhere as well, but, if the forehead is always dry, I am sceptical.
4. The sweating must be worse in cold weather.
5. Must not be due to heavy bedclothes.

If these five conditions are present, sweating at night in children over 5 is mainly due to tuberculosis.

Morning Anorexia.—The second symptom of importance is eating no breakfast. You doubtless remember the eminent man (was it Sir A. Clark?) who said that if a man over 40 ate a good breakfast he would pass him for life insurance. There are few children with active phthisis who willingly and regularly eat a good breakfast.

Fatigue.—The third symptom is that they tire easily. They may forget the tiredness in excitement, but, if so, they collapse afterwards. Many of my cases of phthisis reach home from school so tired they promptly go to sleep.

Other Symptoms.—Other symptoms are legion. Children with early phthisis are constantly catching cold, have headaches, etc. Cough is a matter of chance, the majority of early cases do not cough in the daytime, hence are not dangerous to others. One symptom, which can only be discovered in a fairly intelligent patient, is pain, pain quite apart from pleurisy, occurring early, over a small lung area. It is a feeling of soreness or dull ache, and appears to indicate inflammation commencing in a new focus.

Loss of weight is most important. We are having our children suspected of phthisis weighed monthly.

Temperature.—I often find a rise even in the morning; but rarely in the fibroid cases.

Auscultatory.—In examining the chest, most of us have some special sign on which we lay weight. Professor Grancher laid great stress on any change in the character of the inspiration as indicating a tuberculous focus. I confess that I have tried, in vain, to feel any certainty in regard to this point. The chief point that I generally try to make out is whether there is any area which sounds unlike the rest; the place of difficulty to me is the right apex, as it is not easy to determine variations from the normal at this spot. Two of the doctors who carried out part of the special work in the London schools speak of certain changes they find as indicating an atelectatic condition of lung. These changes are patchy dullness, tubular breathing, and crepitations. I do not believe such a condition exists beyond infancy, except as a pathological curiosity, and in this view I have the support of Professor Osler.²¹ It is common to hear that such and such a sign, such as crepitations at one apex, have no significance, because on the next examination they have cleared up. If there is one thing certain about crepitations due to early phthisis, it is that they may be present one day and not a week later.

THE NATIONAL BALANCE SHEET.

Dr. Newsholme, in his *Prevention of Consumption*, gives most valuable figures. He states that there are 60,000 deaths annually, as well as a heavy financial loss to the country, from phthisis. From the male deaths he estimates that the loss to England and Wales is not far from ten million pounds annually, and that the loss from sickness, or what I have spoken of as the non-efficient workers,

comes to one-fifth of the total loss from sickness, and costs one friendly society alone at least half a million sterling in a year.

It is also stated that one-eleventh of the total cost of pauperism in England and Wales is caused by consumption.

This year the country has a unique opportunity to initiate steps to end this fearful loss of lives and money. Whether or no we consider it is easy to diagnose phthisis in children, every one agrees it is important to do it, and also that it is particularly difficult to diagnose in what Dr. Newsholme calls the "latent stage." But in all the demands made by the various education authorities in regard to the qualifications of their medical officers, I have not seen one which has demanded special skill in this branch of work.

And yet this is the disease which takes infinitely the heaviest toll in men and money; and if we are to stamp it out the cheapest time to do it is in childhood, before the sufferer becomes a broad-winner, and while the disease is in an early stage. Dr. Newsholme urges various steps to improve the present appalling state of affairs. First and foremost, I would suggest that the utmost care should be taken to ensure careful examination of the lungs by competent doctors, under the new scheme of medical inspection of children—and that any idea that it is possible to decide by looking at a child whether he needs "inspection" or examination (which is the present idea of the Board of Education) should be absolutely negated. And then, so soon as we know roughly the number of cases of early phthisis we have to cure, let these children be drafted into open-air schools and cured while cure is easy and inexpensive.

IODINE IN SURGICAL TUBERCULOUS DISEASE.

By W. ARTHUR TATCHELL, M.R.C.S. ENG.,
L.R.C.P. LOND.

WESLEYAN MISSION HOSPITAL, HANKOW, CENTRAL CHINA.

ONE of the most common diseases with which we are confronted in China (as probably also in other countries) is tuberculous disease of joints, bones, glands and skin.

Last summer we had a special number of tuberculous joint cases which either occupied our beds or attended the out-patient department for change of dressing, and it occurred to us to try iodine liniment.

The first case which we seriously undertook to treat by this method was that of a lad with tuberculous disease of the right elbow. As usual, a native doctor had accupunctured the swollen member. Having a poisoned hand myself, I asked my colleague to operate. He excised the joint and removed every vestige of disease. Every possible care and precaution was exercised to secure a good result. After a few weeks, with the usual treatment of iodoform dressings, the condition of the elbow was, as the experience of similar cases had proved us to expect it would be, that it was healed to a certain degree, but with several sinuses persisting. We again put the lad under chloroform and thoroughly scraped the sinuses from which pus was freely discharging. Then we thoroughly swabbed the sinuses with iodine liniment, we did not put in any drainage, but dressed with gauze and wool, replacing the arm upon an angular splint. Two days afterwards we removed the dressings and to our surprise there was not a particle of discharge. Every day after we swabbed the sinuses with iodine liniment, and they healed as though they had been

touched with a magic wand. Before the lad left the hospital he had secured splendid movement. He could write with a Chinese pen and manipulate his chopsticks with celerity.

It is unnecessary to record similar cases or describe the many cases of tuberculous abscesses, ulcerated glands, skin ulcers, etc., which have all entirely healed under this treatment.

Our experience, after over six months' trial, is that, although iodine liniment acts well upon ulcers and sinuses of a mixed infection, the results are not quite so rapid or satisfactory as is its action upon tuberculous disease.

Our *modus operandi* is as follows: We operate or scrape, as usual. Then we thoroughly swab the cavity with iodine liniment (B.P.). A piece of cotton-wool twisted around the end of a probe forms a good swab, and can be graduated according to the size of the sinns. The liniment is applied *every day*. The application does not cause pain, except a momentary sensation, when applied to some surfaces: neither does it destroy tissues, as does pure carbolic acid. Granulations do not become excessive. At the first application we insert a thin piece of gauze or pack lightly, but never at subsequent dressings. Gauze plugs and strips for drainage have undoubtedly been responsible for many chronic sinuses. From the first we give a mixture internally containing syrup. ferri iodi, 1 drachm, and potassium iodide, 5 grains, thrice a day.

In the case of large phagedænic ulcers, which form so large a part of our clinics in China, we first of all either scrape or foment, so as to get access to the base of the ulcer. Then the iodine liniment is applied daily. One of the worst cases of this character that we have been called upon recently to treat involved the entire dorsum of the man's foot and toes, exposing the tendons and bones. It was scraped, and iodine liniment used from the first. To-day it has almost completely healed, and without any signs of the usual extensive granulations.

We happened to mention this method of treatment at a medical meeting, since when I have received several letters from those who have tried it. They all report satisfactory results, so I make no apology for publishing it.

So far, we have failed to discover any reference to this special form of treatment in any available medical literature. Perhaps it has been and is still being used by our more enlightened compeers; but to those who are prepared to persevere with this particular form of treatment we can wish them no higher joy or greater satisfaction than up to the present has been our reward.

THE CONTROL OF INFECTIOUS DISEASES IN AND OUT OF THE SCHOOLS.

By A. D. EDWARDS, M.B., B.S.LOND., B.Sc., D.P.H.,
MEDICAL OFFICER OF SCHOOLS, BOTCHESMOUTH.

ONE of the most important results of the medical inspection of elementary schools will be probably the more effective control of infectious diseases in a community.

The control of epidemics by public health authorities has been developed on systematic lines until it has reached a high degree of efficiency, but inasmuch as the supervision of the schools has been partial only, it has been possible for an epidemic to gather force before it was dealt with seriously. Not infrequently it is found that over 70 per cent. of cases in an epidemic occur in children who have been attending elementary schools, and this fact makes it most desirable that the school in which the first few cases occurred should be put under as complete supervision as possible.

The spread of diphtheria in schools affords a good example of this. A child sickening for the disease may, whilst still attending the school, infect many of its classmates. Pencils are still used indiscriminately by different children in the same class, and the pencil used one day by a diphtheritic child is put into the common box, and the chances are all in favour of its being used by another child on the following day. Children, especially younger children, are continually putting their pencils into their mouths, and a more favourable condition for the spread of diphtheria cannot be imagined in practice. Whilst investigating the rapid spread of diphtheria in one class of a

school, I watched the children for a few minutes. In that short space of time many of the scholars put their pencils into their mouths. I collected all the pencils of the class, made stroke cultures in a few tubes, and the borough bacteriologist reported the presence of the Klebs-Loeffler bacillus in the growth. One diphtheritic child who put a pencil in its mouth would be a potent factor in the spread of the disease among its classmates, and a more powerful stimulus is always given to this spread by the presence in a class, firstly of unrecognized cases of diphtheria ("sore throats"), and secondly of children in whose throats also exists the *Bacillus diphtheriae* (Klebs-Loeffler), and who are sickening for the disease, and able to communicate it to others. In the class mentioned, I took swabs from seven throats, and found the Klebs-Loeffler bacillus in two of the children who were still in the class.

Whatever be the origin of the first case—milk or drains—there is no doubt that the elementary schools play a most important part in the spread of diphtheria, first on account of the overcrowding and bad ventilation which still obtain to a greater or lesser extent in the elementary schools, and secondly on account of the use in common by the children of school materials. Of these, pencils are the most used, but in infants' classes plasticine is also handled in common by the scholars. This modelling material, excellent as it is for kindergarten work, and loved by the children as a substitute for clay, must be regarded as dangerous whenever a case of diphtheria has occurred in a class.

Measures taken to check the spread of infection may be classified as taken: (1) In the school; and (2) outside the school.

In the school itself, it is, of course, necessary to consider the possibility of drain defects as being the first cause of an outbreak, after which attention is given to those conditions whereby the infection is spread from one child to another.

The use in common by the children of school material should be controlled, also the use of drinking cups. The danger from pencils may be done away with by the provision of a small metal pencil box for each child. The box, bearing a small label for the child's name, can be obtained at a cost of one penny, and the children take a pride in seeing that they have their own pencils. When diphtheria has occurred in a class, the use of common materials should be stopped or controlled in a similar way.

The overcrowding in schools, always favourable to the spread of infection, will only gradually be done away with, but the new requirement by the Board of Education of a 9 ft. and 10 ft. basis for infants and older children respectively is a step in the right direction; the gradual replacement of the long desks by dual or even single desks, apart from their advantages in the way of back-support and comfort, and lessening of eye-strain, will aid to some extent the diminution of infection, as also will the routine disinfection of schools.

Not the least important matter to deal with in the schools is the presence in a class of children who have the *B. diphtheriae* in their throats, who are sickening for the disease or are suffering from it in a mild form ("sore throats"), and who are possible sources of infection to other children. And herein the aid of medical inspection to the public health should be at its greatest value.

When a case of diphtheria occurs in an elementary school child the school medical officer visits the class and examines the children's throats. The use of wooden spatulas, one for each child, the spatulas being destroyed after use, is necessary. All cases of sore throats are excluded from the class, swabs being taken at the time. In this way would be removed those children in whom there was diphtheria in a mild and unrecognized form.

By the term "*Bacillus diphtheriae*" is meant the true Klebs-Loeffler bacillus, possessing the accepted cultural and morphological characteristics. The variation in virulence of this true diphtheria bacillus is recognized; but even when the virulence is very low, provided the morphological type and such characteristics as the polar staining with Neisser's method are retained, it is regarded as the true bacillus of diphtheria (Klebs-Loeffler). As such, its presence is a reason for regarding a throat as a means of infection to others. The pseudo-diphtheria bacilli may or may not be convertible into the

true bacillus; the evidence is at present all in favour of this view, but the fact is not proven; and in the practical efforts to check the spread of the disease no more can be done than to obtain some control over those children in whose noses and throats are found the true diphtheria bacilli. This at least is possible in practice, and, inasmuch as such control is based upon facts proven and knowledge certain, it is both desirable and justifiable.

So widespread are the pseudo-diphtheria bacilli so frequently found in the "normal" throat that the control of each child harbouring the Hoffman bacillus in nose or throat is not within the range of practical administration. Even if it were proved beyond doubt that the Hoffman bacillus may become the true type bacillus—and this is possible at any time—it would be necessary still to show that the change occurred frequently or rapidly. If it were so proved, it is to be hoped that some indication and warning will be found more useful and more sure than the vague "lowering of resistance" so often referred to.

This outline has been confined to the methods of control in the school. The sanitation and drainage are found to be perfect, the school premises have been efficiently disinfected, sources of infection such as pencils and other common-use materials have been controlled, cases of suspicious throats have been excluded, and thus a fairly complete check is put on the infection in the school.

But what about the further control of these "sore-throat" children who have been excluded from school? They still remain possible sources of infection outside the school, and it is here that the Public Health and the Medical Inspection services should meet; there should be no gap through which these cases might escape, and, free from control, continue the infection.

The "sore-throat" cases, of which many may be mild diphtheria, recover and return to school, still harbouring the bacilli in their throats and noses. When a child is certified to be suffering from diphtheria and is taken to the sanitary hospital, it is not allowed to leave the hospital until two negative swabs have been taken from the nose and throat. The London County Council has an excellent regulation that during the prevalence of diphtheria in a district, no children excluded from school on account of diphtheria or sore throat may return to school until they have obtained a medical certificate, based on a bacteriological examination, that they are free from diphtheria.

The phrase "during the prevalence of diphtheria in a district" gives the key to the situation. A sore throat occurring in a child may or may not be a serious matter, but a sore throat in a child who is in a district where diphtheria is prevalent, and who has been in contact with diphtheria cases, must be regarded seriously. The child is a "contact" case, and it is a most desirable thing that cases of "sore throat" excluded from school should be followed up. Where the medical inspection branch is administered from the Public Health Department this can be done by a health visitor, part of whose duties would consist in visiting and obtaining information concerning these excluded cases. Such a health visitor would be a trained nurse, having experience of fever hospital work, and possessing the Royal Sanitary Institute's certificate for health visitors; and it is a matter of great importance that she should be possessed of such tact and patience as would enable her to carry on her work quietly and unobtrusively and yet thoroughly. A child who had been excluded from school on account of a "sore throat" with the coincident circumstance of being a "contact" case, might or might not have diphtheria. The health visitor, on her visit to the home, explains things to the parents, advising them to consult a doctor, and a form is given to them for the doctor. The following form would be suitable:

Date

Dear Sir,
To the Medical Attendant.
I have examined, a scholar at the
..... School, and have excluded (him) (her) on account
of a condition of Sore Throat.
At the time of exclusion, a throat swab was taken, which
on Bacteriological examination gave a {positive} result for
the Klebs-Loeffler bacillus. {negative}

Yours faithfully,
.....
School Medical Officer.

The medical man whom the parent consulted could then

take charge of the case, and, if it was diphtheria, would notify in the ordinary way. By these means these excluded "sore throats," diphtheria or not, would come under medical supervision, they would not be free to continue the spread of the disease.

The methods described for diphtheria would be applicable in a modified form to the cases of scarlet fever, and also, to a slighter extent, to the non-notifiable diseases. There is no doubt that scarlet fever is spread to a great degree in schools by the very slight and unrecognized cases, which are sometimes not noticed at all, and often noticed only when the child begins to peel. The rapid examination of a class in which scarlet fever had occurred would enable the school medical officer to exclude promptly these unrecognized cases. Teachers can be educated to recognize suspicious cases. Sore throats, and even a rash in the case of scarlet fever, weeping eyes and nasal catarrh at the onset of measles, are signs which should enable an intelligent teacher to exclude the child.

The teachers are often able to give information to the medical officer concerning children away from school on account of the non-notifiable infectious diseases. Accurate information concerning the spread of the non-notifiable diseases is difficult to obtain, but a fair indication can be obtained by the system whereby the school attendance officers send a form to the school medical officer. When an attendance officer visiting the home of an absentee finds that the child is suffering from measles, whooping-cough, varicella, or other non-notifiable infectious disease, he fills in a form and posts it to the medical officer. The form is on a card which can be used in a card index system. The disadvantage of this system is that the information may come a few days after the child has fallen ill, but it at least gives information concerning the spread of the non-notifiable diseases; and it can be supplemented by a card sent by the teacher on the occurrence of the first case of each disease occurring in the school. This would be early information, and information concerning the first case of an infectious disease occurring in a school is often of great value to the school medical officer in his efforts to check the spread of infection in the schools.

It is probable that as the system of school medical inspection becomes fully developed, the closure of schools on account of epidemics will become less frequent. The leading public health authorities agree that closure of elementary schools is of doubtful value in checking the spread of measles, except in country districts where the school is the one and only meeting place of children. In town, the children meet and mingle in many places and on many occasions. Usually schools are closed only after a large proportion of children have developed measles, and this fact may contribute to the non-success of the measure, but there is one method of closure for measles, recommended by the Local Government Board, which is of particular value in safeguarding the children under 5 years of age. The attendance of these children at school is not compulsory, but large numbers of them are sent to school, and under certain economic conditions, when they cannot be looked after and cared for properly at home, it would be an advantage for these children to attend school if the school premises were efficiently ventilated and the general conditions were good, and the young children were allowed to sleep in comfortable positions when they wanted to. Any one who has visited a babies' class in the afternoon will have seen many of the children sleeping with their heads on their desks. The report made to the Board of Education recently by its special committee recommended that for children 3 to 5 years old school nurseries should be provided, isolated from the main building in order to reduce the risk of infection.

But under present conditions something can be done to protect these younger children, to bring them to the age of 5 or 6 without contracting measles—a desirable end, for the measles mortality among children under 5 years old is very great. If early information is obtained concerning the first case of measles in an infants' school, the school can be closed from the ninth to the fifteenth day with good effect. The first measles child may have infected others in the school, but those children who have caught measles will not be infectious until about the ninth or tenth day. As the school is closed on the ninth day these children will not spread the disease in the school; also,

all the children who have caught measles from the first case will sicken between the tenth and the fifteenth day—that is, during the time the school is closed. The advantage of the short closure of six days will be apparent to educationalists.

It is evident that full co-operation between the public health and the medical inspector's departments is necessary in order that these methods be carried out thoroughly, and such co-operation will surely lead to the strengthening of the weak points in our defence against the infectious diseases of childhood.

THE MEDICAL ASPECT OF DENTISTRY AND THE NECESSITY OF DENTAL INSTRUCTION FOR MEDICAL STUDENTS.*

By H. PERCY PICKERILL, M.B., Ch.B., B.D.S. (HON.),
L.D.S. (ENG.).

PROFESSOR OF DENTISTRY IN THE UNIVERSITY OF OTAGO AND
DIRECTOR OF THE DENTAL SCHOOL.

THE historical associations between medicine and dentistry date from very early times. Hippocrates, besides studying medicine, devoted some attention to dentistry. He invented forceps for the extraction of teeth, observed the necessity for the proper cleansing of the teeth, and for this purpose prescribed the following dentifrice:

A charmed rabbit's head and three charmed mice ground into a powder.

He also recognized the fact that destruction of the bone of the jaws might follow affections of the teeth—and might even end fatally. Celsus also practised dentistry, and in his *De Medica* he advocates filling carious teeth with pieces of slate wrapped in cotton. Galen differentiated between inflammation of the pulps of teeth and inflammation of the root membrane, and prescribed a number of tooth-powders and mouth washes. To come down to more modern times, that famous surgeon, Ambroise Paré, in the sixteenth century devoted considerable attention to the treatment of teeth, and invented a splint for holding loose teeth in position, as well as several forms of forceps. The great John Hunter did not omit the teeth in his multifarious researches, and wrote a most accurate treatise upon the *Natural History of the Human Teeth*. But here comes a hiatus. Since the time of John Hunter until quite recent times medical practitioners have taken but little interest in dental diseases, probably because dental practitioners began to spring up and the matter was left to them, but also, alas! I am afraid, because the practice of dentistry was associated for a long time with a certain element of shamed-facedness, if not of quackery, and medical men passed it by on the other side. This position is now, however, no longer tenable, because it is now recognized that dental, medical, and surgical diseases are so intimately related that a proper conception and therefore treatment of one is impossible without some knowledge of the other. In order to substantiate the statement I will proceed to give definite instances of the intimate cause and relationship existing between dental and medical lesions.

Quite a lengthy list of ailments, from appendicitis to glaucoma, have been ascribed to the direct or indirect influence of the teeth, but I shall confine myself to those which have been well established, and in which I can to some extent speak from personal experience. These may be classified as being due to:

- (1) Reflex irritation;
- (2) Direct extension of morbid process; or
- (3) Septic absorption.

LESIONS DUE TO REFLEX IRRITATION.

Epilepsy.—Attacks of this disease are undoubtedly set up by peripheral irritation, not the least of which is dental caries; many cases have been reported, and one case is recorded in which the patient always developed an attack of *petit mal* when visiting his dentist. I have had one definite case in which the patient, a little girl, did not

show any marked improvement despite excellent medical treatment until her teeth were treated. The attacks then subsided. Some twelve months afterwards a recurrence of dental pain in another tooth was followed by a further attack of epilepsy, and this did not recur after the tooth was filled. Hysteria has also been said to be due to dental irritation, but I am more inclined to think that odontalgia is more usually a symptom of hysteria.

Neuralgia.—Neuralgia of the fifth nerve and the *trigeminal* are too often associated with dental troubles to need any verification. Brachial neuralgia may be due to irritation arising from the teeth. I have myself seen three such cases. In all three the pain was confined to the region of the circumflex and cutaneous branch of the musculospiral nerves. It was associated with exposed pulps in lower premolars, twice on the right side and once on the left; in each case pain started in the tooth, and then leaving the tooth became as it were transferred to the shoulder and arm, and only yielded to the devitalization of the affected dental pulps. In one case the pain ceased within half an hour of treatment, despite the fact that the patient had been unable to sleep all night on account of the pain in the shoulder. A considerable number of cases have been recorded of facial paralysis due to dental lesions; this in many cases is undoubtedly due to the close association between the fifth and seventh nerve through Meckel's, the otic, and submaxillary ganglia.

"Spurious" Tetanus.—Many cases of this condition, which is quite common, were formerly supposed to be due to the teeth. It is now known as trismus, and in some cases may be due to irritation of the branch of the fifth nerve supplying the masseter, but is more frequently due to a local cellulitis about the angle of the mandible caused by the suppurative at the apex of a lower third molar.

Cardiac Irregularity.—Sir R. Douglas Powell¹ records a case of "excessive" cardiac irregularity and spasmodic heart pains "which a course of Naheim baths and resistance exercises only slightly relieved," but was completely cured by attention to the teeth, which were "extensively decayed and surrounded by tartar."

Pelvic Pain, etc.—Instances of leucorrhoea and uterine pain synchronizing with dental pain and ceasing on the removal of the tooth have been recorded. Conversely, dental pain is often associated with uterine disturbance; several such cases have come under my notice, one quite recently, in which the severe dental pain occurred every month at the menstrual period in quite healthy teeth (second upper molars), and was not relieved by any dental treatment, not even by extraction, but was "transferred" to the first molars.

Ear Disorders.—Affections of the ear are frequently associated with dental irritation. Neuralgia of the ear is very frequently merely referred pain from a carious tooth; many of us must have had subjective experience of this, especially if we have had the misfortune to bite suddenly upon an exposed pulp. Hilton, in *Rest and Pain*, mentions a case of persistent purulent discharge from one ear which only yielded to treatment after removal of a carious molar, and he suggests that "the reflex irritation had led to interference with nutritive function of the nerves supplying the external meatus."

Eye Disorders.—This interference with the neurotrophic function is undoubtedly present in many obstinate cases of conjunctivitis; I have seen several such cases. Many cases of spasm and paresis of the ocular muscles have been recorded as being due to dental irritation.

Local Cellulitis.—Among diseases due to direct extension of the morbid condition of the teeth may be mentioned cellulitis of the face and neck, of which I have seen two fatal cases, one in a man aged 40, another in a woman aged 35, both arising from lower third molars. In another similar case the patient barely escaped with his life owing to the exceedingly high temperature, septic absorption, and inability to take sufficient nourishment on account of the severe trismus present. I remember Mr. Levason, with whom I was associated for some years, treating a case in which an abscess arising from a mandibular molar had tracked down beneath the cervical fascia, and was eventually opened in the axilla. Empyema of the antrum occurring through dental infection is too well known to need any verification. The *Streptothrix actinomycetes* occasionally finds a way into the jawbone through

* Read at the Otago Section, New Zealand Branch, of the British Medical Association. For many references in this paper I am indebted to Messrs. Smile and Colyer's excellent work on *Diseases and Injuries of the Teeth*, chapter xix of which I would suggest might be published as a separate pamphlet for the use of medical students.

a carious and septic tooth, and gives rise to the characteristic "lumpy jaw." One such case which I saw gave rise to considerable difficulty in treatment, having been treated for cellulitis, alveolar abscess, and non-eruption of the third molar, until I was fortunate enough to find the organism.

Myeloid sarcoma frequently originates from the fragment of a buried root. Mr. Jordan Lloyd is a firm believer in this, and I have on two occasions seen him find the bit of tooth which caused the growth; and to satisfy him I made sections of the fragment to verify its dental structure.

Epithelioma.—It is common knowledge to all how epithelioma of the jaw or tongue may follow irritation from a rough tooth. But there are cases of burrowing epithelioma of the jaws which I believe arise from the irritation (by a septic tooth) of embryological remains of the epiblast, which are nearly always present—and known as the epithelial sheath of Hertwig—in the periodontal membrane. Many cases of ulcerative stomatitis, which may develop into cancrum oris, unquestionably arise by infection from septic teeth, and it is impossible to successfully treat the stomatitis without attention to the teeth. It is just possible that some cases of acute septic endocarditis may trace their origin to infection from the teeth and mouth. At least, in one such case I found the same organisms—a staphylococcus, *Streptococcus brevis*, and a short bacillus (? the *Bacillus necrodentalis* of Goadby)—present *post mortem* in the mouth, bronchi, the alveoli of the lungs, and on the valves of the heart.

Local Conditions not Dental.—Conversely there are many local conditions of the mouth which are liable to be mistaken for dental affections. For instance, I have seen a whole roomful of medical students mistake a primary chancre of the lip and jaw for an alveolar abscess, and a case of bilateral odontotoma was for months treated as alveolar abscesses. A man whom I saw not long ago suffering from epithelioma of the superior maxilla was treated for some time for a simple ulcer of the mouth. Some four years ago I remember seeing a case in which during life the only symptom was constant odontalgia of the left side; the teeth were all perfectly sound, the patient felt ill and depressed, but there were no signs whatever. *Post mortem* a glioma about the size of a pigeon's egg was found just over the left Gasserian ganglion.

Chronic Lymphadenitis.—But to turn to a more frequent and more overlooked class of cases—those due to septic absorption from the teeth and mouth. The association of chronic lymphadenitis with carious teeth is now quite recognized. Several series of statistics have been compiled, but those of Odenthal of Bonn are perhaps the most conclusive, and are as follows:

Children examined	...	987
No glands and no carious teeth	...	28.6 per cent.
Glands enlarged	...	70.7 "
Glands and caries	...	50.0 "
Caries and no glands	...	0.5 "

I am unable to say whence these statistics were obtained, but, even if it were from a very "tuberculous" district, the fact that only 0.5 per cent. showed caries without gland enlargement is very significant. A chronically inflamed gland is one which probably is tuberculous or is likely to become so, and in carious teeth associated with tuberculous cervical glands tubercle bacilli have been found.² (I have found them in the saliva, but have not succeeded in demonstrating their presence in the teeth.)

Pyorrhoea Alveolaris.—The condition known as pyorrhoea alveolaris, "Riggs's disease," or more correctly marginal periodontitis, is even more closely associated with general systemic conditions than is dental caries. This disease may be defined as a suppurative condition of the upper part of the periodontal membrane due to an upset of the balance between the resistance of this latter tissue and the ordinary organisms of the mouth. The latter may become more virulent or the oral tissues may become less resistant, owing to: (a) The local accumulation of salivary calculous material, or (b) the presence of some general systemic disorder, such as gout, rheumatism, chronic alcoholism, chronic heart, kidney, or lung disease, diabetes, syphilis, or plumbism. When once established it is difficult to treat. The patient usually complains of

malaise, dyspepsia, loss of appetite, and constipation, accompanied by a malodorous breath, disagreeable taste in the mouth, and occasional expectoration of pus, or purulent saliva. Some amount of anaemia is always present, and loss of body weight is marked in prolonged cases. The teeth are always more or less loose, the gums red, swollen, and glazed, and pus can be extruded from the space between the gum and the tooth. Strange to say, the teeth are not always tender, and this latter fact often misleads the patient, and sometimes his medical adviser, as to the cause of his trouble. Mr. Rickman Godlee records three such cases.³

One, a lady aged 40, who was treated for two years for lung trouble with no cessation of symptoms. Pyorrhoea was then found to be present, was treated, and the expectoration (which had consisted, to use the patient's own words, of lumps of green and yellow stuff) completely stopped.

Another patient, aged 25, presenting symptoms similar to the last, but with marked loss of body weight, was treated in the same way, with the result that, in her own words, "Life was again worth living."

In the third case, Mr. Godlee ascribes several attacks of acute trouble, accompanied by stomatitis and glossitis, to an exacerbation of a previous suppurative periodontitis.

It cannot now be doubted that this condition of pyorrhoea alveolaris is responsible for a large proportion of the cases of pernicious anaemia. Dr. W. Hunter goes so far as to say that he believes that the infection arises in nearly all cases from the mouth. It is, however, generally conceded that this condition arises from toxic absorption from some part of the alimentary tract, and of the latter, the mouth is, *a priori*, the most probable part. I have had two definite cases, both in men about 40 years of age. They both suffered from marked suppurative periodontitis.

The first was a typical case—"anaemic," lemon yellow complexion, muscular weakness, malaise, loss of appetite, etc. A blood count showed only 1,700,000 red corpuscles per c.mm. and haemoglobin 41 per cent. The patient was seen early, the pyorrhoea treated and arsenic given in increasing doses. He made a gradual recovery.

The second case did not come under treatment until both the local and general conditions were very advanced. The only hope of eradicating the disease was by extraction of the teeth, and to this course the physician with whom I saw the case would not agree, thinking the risk of haemorrhage too great. In spite of local and general treatment the man died.

These two cases serve to illustrate many similar cases which have been recorded, and establish the necessity of at any rate eliminating oral sepsis in all cases of pernicious anaemia. Dr. Dauber, of the Women's Hospital, Soho, has recently come to the conclusion⁴ that septic teeth have a distinct influence upon uterine and ovarian conditions, and gives many instances in which the gynaecological lesion has only yielded to treatment after the oral conditions have been corrected. Mr. Kenneth Goadby in the Erasmus Wilson Lecture for last year records a number of cases of pyorrhoea alveolaris wherein marked improvement and in some cases absolute cessation of both local and general symptoms ensued after raising the opsonic indices of the patients to the organisms found in the periodontal discharge.

Prevention.

Even when these conditions are treated by the only means often available or possible—that is, the extraction of the teeth—we do not arrive at a much better state of affairs, for how large a proportion of the chronic gastric and intestinal cases filling the medical wards and the out-patient department of our hospitals is formed by prematurely toothless middle-aged men and women!

The only rational hope lies in the preventive treatment of dental disease, and therefore the next stage in my argument is a brief reference to the causes of dental caries. This, like many other diseases, is not the outcome of one single and specific cause, but is the resultant of several coincident forces which may be summarized as:

1. A lowered resistance on the part of the buccal and dental tissues.
2. The action of certain organisms.
3. The presence of fermentable carbohydrates.

These three factors must be coincident. The total elimination of any one factor would prevent the occurrence of caries. The first stage of the formation of a carious cavity is chemical, and the first step is obviously all-important. Many mouth organisms are capable of

fermenting carbohydrates with the production of acid, chiefly lactic but occasionally butyric acid. A reference to the accompanying table will show that monosaccharides are the most readily fermentable. Disaccharides require to be first inverted to monosaccharide by an enzyme formed by certain of the mouth organisms before lactic acid is produced. Starches require a double inversion, the first stage brought about either by ptyalin or organisms, before fermentation to an acid can occur, but in all cases it is seen that lactic acid is the end product unless, as occasionally happens, this lactic acid is again split by the action of organisms to yield butyric acid.

Thus it is very evident that if carbohydrates remain in contact with the tooth for a sufficient length of time an acid is tolerably certain to be produced (because the necessary organisms are practically always present), and this acid dissolves the lime salts of the enamel, and a cavity is originated at the point of action.

Bearing in mind these facts, it is obvious that anything which favours the lodgement of carbohydrates on or around the teeth very much increases the risk of caries. Certain carbohydrate foods, such as biscuits, chocolates, caramels, soft white bread, cakes, and scones, are of themselves very adhesive. Milk, too, tends to leave a film upon the teeth, which readily yields lactic acid.

It is, perhaps, interesting to observe at this point the comparative consumption of sugars in the various countries as shown in the following table:

Sugars Consumed per Capita, 1905.			
New Zealand	108.64 lb.
United States	92.46 "
Great Britain	77.83 "
Excess of New Zealand over Great Britain	30.81 "

Without reference to statistics, I should say that the incidence of dental caries in these three countries is roughly in the same proportion as the above figures.

But just as important as this is the configuration and structure of the teeth. Teeth irregularly disposed and crowded together will retain more foodstuffs in inaccessible positions than teeth normally placed. The same is true of teeth showing numerous pits, crevices, and other developmental defects in the enamel. Some of these irregularities are hereditary, some are due to accidental causes and habits; but the vast majority are due to one cause—non-development of the mandible—and this in turn is due to improper diet. It is significant that all these irregularities arise between the ages of 6 and 12. It has unfortunately become the custom of civilized people to feed children between these ages upon comparatively soft and pappy food which does not exercise their muscles of mastication. It is a well-known fact that those bones having the strongest muscles attached to them are developed most, and vice versa. The tongue also is one of the most important organs of mastication, and has a direct moulding and expanding influence upon the mandible. If the tongue does not develop, the mandible does not fall in, but it never expands; and the teeth, having been already formed, when they erupt adopt irregular and misplaced positions. Figs. 1 and 2 represent the shape of the mouth and the disposition of the teeth when this has occurred, and this is becoming so frequent an occurrence that these shaped arches are becoming the "normal" condition.

But not only is the horizontal plane of the bones affected, but also the vertical. This in the maxilla becomes "V" shaped as shown in Fig. 3. Fig. 4 shows what should be the normal shape of the oral and nasal

cavities. This "V" shaped arch does not arise from lack of development, but from insufficient expansion, for it has been shown by measurements of these cases that the distance between A B and A' B' remains the same. The effect on the nasal cavities is obvious—their vertical and horizontal measurements are greatly diminished; further, if the nasal septum has an inherent tendency to growth, this can only occur by its becoming deflected. The result is that nasal breathing becomes more difficult, and, in any slight inflammation of the nasal mucous membrane, impossible: the patient acquires the habit of mouth breathing, adenoids develop in the stagnating cavity, and the tonsils enlarge. A vicious circle is thus established,

Fig. 1.

Fig. 2.

for persistent mouth breathing leads to further irregularities of the teeth, and deficient expansion, especially of the maxilla.

These statements may be summarized as follows:

Lack of any hard or fibrous food causes under development of the tongue and other masticatory muscles. A weak, small tongue fails to expand the mandible, which in turn does not expand the maxilla, and therefore the nasal cavities remain small and ill-developed.

The dependence of the upper alveolar arch upon the lower is obvious upon reference to Figs. 3 and 4, where it is seen that the teeth articulate by means of inclined planes, and that the inner cusp of the lower teeth always closes inside that of the upper tooth, and thus any outward

Fig. 3.

Fig. 4.

movement of the lower teeth must be followed by a similar movement of the upper teeth. This system of double inclined planes ensures the parallel movement of the whole of each tooth, and prevents the mere outward movement of the crown swinging upon the apex of the root as on a pivot. This is experimentally proved by the fact that most cases of the type of irregularity of the upper teeth seen in Fig. 1 can be remedied by an expanding or other device inserted on the inner aspect of the lower teeth; and this practice I have adopted for some time with success.

Foodstuffs also play an important part in the development of the teeth. If the mother during the period of gestation exists upon a diet poor in lime and phosphates, the child's teeth will probably be poorly developed. The same thing applies to the diet of the child between the ages of 12 months and 12 years, when the permanent teeth are developing.

There is a popular idea that it does not matter what happens to the deciduous teeth—one frequently hears the

expression, "Oh, but they are *only* his first teeth." Consequently the child is given all sorts of rubbish to eat under the belief that it does not matter. But it *does* matter, for two very important reasons:

1. An exceedingly bad habit is thus contracted by the child most difficult to eradicate when the permanent teeth arrive.
2. Broadly speaking, carious deciduous teeth mean carious permanent teeth.

Caries of the deciduous teeth causes contraction of the alveolar processes by allowing the teeth to come closer together, and thus leads to crowding of the permanent teeth and all its attendant evils. Caries of the deciduous teeth most frequently leads to alveolar abscesses, which infect the underlying permanent tooth germs and arrest their development, with the result that the teeth are erupted in a hypoplastic condition, and fall an easy prey to caries. A soft diet also impairs development of the permanent teeth by not exercising the jaws, and therefore not stimulating a sufficient blood supply to the ameloblasts and osteoblasts of the dentine papilla. We are therefore driven to the conclusion that from whatever standpoint the subject is considered, the prime factors in the causation of dental caries are errors of diet—chemical and physical.

What, then, can be done? That something should be done is gradually coming to be recognized on all sides; that so little has been done up to the present is most astonishing when one considers that dental disease of some kind is present in 80 per cent. to 90 per cent. of the people of civilized races. It is thus indubitably the most widespread of all diseases, and, as I have attempted to show, is far-reaching in its effects. But, unfortunately, cause and effect are not always associated.

There has been in the past, both in dentistry and medicine, too great a tendency to regard the teeth as isolated parts of an organism, as organs which exist of themselves and for themselves, and not intimately linked up in function with the rest of the body. Pawlow showed that mastication was the natural, and therefore the best, stimulus for gastric and saliva secretion; and efficient mastication implies an absence of caries. The teeth, it must be recognized, are an integral and inseparable part of the alimentary system, physiologically and pathologically. It is this fact, together with all that it implies, which should be impressed upon a medical student. I have heard abdominal surgeons express the opinion that, in view of the increasing number of gastric and intestinal cases, there is "a something" at work which is appreciably lowering the resistance of the alimentary tract. In my opinion this something is to be found in the enormous strain thrown upon it by the constant ingestion of improperly masticated food, incorporated with organisms (more or less virulent), toxins, and pus from diseased teeth; and also because of the avoidance of hard food, in part secondary to the tenderness of the diseased teeth. The intestines become atonic, having to deal only with non-fibrous easily-digestible substances. Any organ or organism which is overstrained or is atonic falls an easy prey to the attacks of micro-organisms.

Dental caries is largely due to errors of diet commencing before birth and extending over the first twelve years of a child's life. It is just during those periods that a medical man's advice is most often sought as to the suitability or otherwise of articles of diet, or, at least, he has opportunities of pointing out authoritatively the deleterious effects of common dietetic errors; and on account of this, in my opinion, a large percentage of the prevalence of dental disease lies at the door of the medical profession. We should therefore do all in our power to remove this stigma. A medical student, before he qualifies, should have some knowledge of what diet is beneficial and what deleterious to the teeth, and he should be taught to put this into practice; in doing so he will only be fulfilling the general principles of correct dietetics, for it might be stated in general terms that "what is best for the teeth is best for the rest of the alimentary system." He should also know something of how to aid natural resistance to caries by artificial prophylaxis; he should be able to write suitable prescriptions for various mouth washes, dentifrices, etc., for varying conditions of the mouth; he should be able to instruct parents in the care of their children's teeth. All this and more he should know. He is taught along similar lines with regard to the eye, and ear, and

throat; why, then, should the teeth and mouth be omitted?

Medical men are often so situated as to be compelled to relieve dental pain, and I do not think I shall be hurting the feelings of any member of this Association when I say that this relief is most usually afforded by the extraction of the offending molar. But this is not as it should be. Therefore I would have the medical student to know the value of a tooth—to know when it can be lost and when it must be saved. The mere extraction of one tooth will often ruin a patient's articulation.

A medical student, too, should be able to recognize the difference between dental myelitis,* periodontitis, and alveolar abscess, and be able to relieve the pain of each of them without extracting the tooth should this be desirable. A medical man is often asked by a patient for an opinion as to dental treatment, or may be called in consultation with a dentist; in either case he will find such knowledge extremely useful, and it will obviate those awkward *contretemps* when the doctor says one thing and the dentist another. I am not suggesting that the dentist is always right; he is apt sometimes to take a narrow view of things, and forget that the teeth are necessary to the proper functioning of the rest of the body, and I have known a patient's general nutrition and health seriously impaired by injudicious dental treatment. It may be thought and said that I would make every medical man a dentist. That is not so, but, even if it were so, it would be only fair to the public, since every medical man is entitled legally to practise dentistry, irrespective of any dental training. On the other hand, in passing, I may say that I should like to see the converse true—that is, every dentist with a medical qualification. A medical student should also recognize the effects of measles, scarlet fever, rickets, and syphilis upon the teeth. He should be thoroughly imbued with the absolute necessity of close attention to the oral hygiene of patients whose treatment necessitates a prolonged milk diet, as in typhoid and surgical abdominal cases. He should know something of the treatment of fractures of the jaws by interdental methods.

The necessary amount of knowledge could be acquired by a medical student in a very short time; it would add no time to the length of his curriculum, and he himself would, I think, be the first when he got into practice to appreciate its value.

The medical inspection of school children is looming ahead, and it is highly improbable even if it were expedient that dentists as well as doctors will be appointed, yet it is very necessary that an efficient and reliable examination and report on the children's teeth should be made, as well as of other organs. Therefore on this account also it is desirable that medical practitioners should have some accurate knowledge of dental matters. This can be obtained in two ways: First, by making it necessary for every student before sitting for his final examination to present a certificate showing that he has received instruction in dental surgery, including a few lectures and practical instruction in the extracting and dressing of teeth. Secondly, to ensure that students should take this seriously by occasionally setting a dental question in the medical examination papers.

In order to facilitate the practical part of this scheme and in order to render the possible treatment of many medical and surgical cases more logical there should, of course, be an efficient dental department attached to every public hospital and dispensary.

In conclusion I would appeal to you, if I have convinced you of the desirability and practicability of these suggestions, that you will not be content with mere expressions of opinion but that you will take some active step towards the attainment of this object—that it may ever be the proud boast of the medical profession that it strives to the best of its power to eradicate those diseases from the incidence of which it derives its livelihood.

FEEDING TRIAL IN RELATION TO
"EPIDEMIC ENTERITIS"

BY E. P. MINETT, M.D., D.P.H.

ASSISTANT BACTERIOLOGIST, GUY'S HOSPITAL.

THE possibility of using a practically sterile food for infants in relation to infantile summer diarrhoea, or "epidemic enteritis," has been considered from many points of view, all or most of the methods used starting with cow's milk as their basis.

Now as the case incidence of this disease in large town and crowded areas, as compared with rural districts, seems to be double, or practically so (11.5 against 5.0), it appeared probable that an experimental feeding of a number of infants living in their own homes, and in crowded and poverty-stricken districts, such as Bermondsey and Southwark, would be instructive both from a medical and bacteriological point of view, especially if the experiment were conducted during the summer months, in which the case incidence of this disease is highest.

It was with the object of collecting data with reference to this subject that some feeding trials were conducted with infants collected from various sources—the outpatient departments of Guy's Hospital, Royal Waterloo Hospital for Children, and the Surrey Dispensary. Special food was provided gratis for the use of selected infants in their own homes. The infants were brought up to the dispensary weekly, where they were weighed and medically inspected, while charts of their weight were carefully kept, together with notes as to the occurrence of rickets, scurvy, and especially diarrhoea.

The method employed was by using dried milk, of which there are several varieties on the market, prepared principally by German, French, and English firms, the last-named drawing their supplies from a particularly pure and carefully supervised source in New Zealand. Briefly, the method of preparing dried milk is as follows:

The cows are first inspected with reference to disease, such as tuberculosis, etc., by a veterinary officer. A contract is then made with the farmer, who undertakes to deliver the milk at the factory within three hours of milking. On receipt it is cooled by running over a cooler which has water at 50° F. running through it. Meanwhile the cans in which the milk was delivered are placed in a trough full of lime water; afterwards they are rinsed by being placed over a jet of cold water, and then over a jet of superheated steam, finally they are again rinsed with a jet of cold water before being returned to the farmer. A sample of the milk after cooling is now estimated for butter fat by Babcock's process, and farmers are paid in New Zealand for the milk on the basis of its butter-fat contents. Next the cooled milk is filtered by pressure through a filter composed of four prepared pieces of filter paper and a specially prepared cloth, to remove any dirt and filth present. I am informed that the amount of filth removed from even the most carefully collected samples is surprising. The mixed product having been again standardized to secure a product as nearly constant in composition as possible, the moisture is abstracted by allowing the milk to fall in a constant thin stream over revolving cylinders, heated by steam to a temperature of 240° F. The milk is in contact with the cylinders for about 2 seconds only. The dried powder is then removed mechanically and at once packed in hermetically sealed tins for export.

The efficiency of the process to destroy any organisms, whether pathogenic or otherwise, present in the original milk, may be inferred from the following passage occurring in Dr. Klein's description of several of his experiments: "Notwithstanding the prodigiously large number of specific organisms with which the sample had been infected by me, none of them could be detected after the milk had been subjected to this drying process."

The method I employed, which was found to be the easiest both from the distribution and feeding point of view, was as follows:

Each child, when first taken under treatment, was carefully weighed, then thoroughly examined with a view to rickets, scurvy, marasmus, etc. A chart was made out with notes, and a card given to the mother. To each mother was given a sealed tin of the milk, bearing printed instructions as to feeding, for easy reference; also a small measure holding roughly a drachm weight of the food, together with two bottles and a supply of teats, the latter of the variety that will fit over the neck of almost any bottle.

According to the infant's age the mother was instructed to put so many measures of the dried milk into the

bottle, previously rinsed out with boiling water, and then to fill up with boiling water to a mark made on the bottle with a file. This obviates all the trouble to the mother of weighing the powder or measuring the water. Roughly, 1 of powder to 7 of water is the strength of food we usually start with, and a table, as given below, is supplied for their guidance to the nurses who distribute the food.

Age of Infant.	Intervals of Day Feeding.	No. of Night Feeds.	Boiling Water.	Dried Milk.
1 week	2 hourly	2	1 oz. to 1½ oz.	1 measure.
2 to 3 weeks	2 hourly	2	2½ oz.	2 measures.
4 to 5 weeks	2 hourly	1	3 oz.	2 to 2½ measures.
6 to 12 weeks	2½ hourly	1	4 oz.	3 to 3½ measures.

and so on in about the same ratio.

No fixed quantity was given, the amounts being varied according to the results of observations by the medical officer, each child being prescribed for separately, and the food modified as occasion demanded. The mothers' attention was also drawn to the fact that, as some of the fat separates out and floats on the surface, the bottle requires shaking occasionally during a feed. Printed instructions were given to the mothers, and insisted on by the nurses, as to scalding bottles and teats when not in use, and also as to the importance of making each feed separately, and not keeping a feed, or part of one, from one feeding time to another. I prescribe, in addition, a small quantity of orange, or sweetened lemon juice to be given daily with a teaspoon after one of the feeds.

The results as to weight were most gratifying, the infants gaining in weight from 4 oz. up to 10 oz. weekly, the average weekly increase being about 6 oz. The worst drawback we have to contend with is the fact that the mothers will not bring up the children regularly to be weighed and inspected, even although the food, bottles, and teats are all supplied gratis. They will often miss several weeks at a stretch, and frequently drop off altogether after a few weeks, just as the child has begun to make progress.

With regard to chemical composition, I used two varieties of dried milk—the half cream and full cream—the difference, of course, consisting mainly in the amount of fat present.

As the experiment only ran for about eighteen or nineteen weeks, comparison of their respective merits cannot be made, the incidence of diarrhoea being the special object aimed at. The cost, if the mother had to buy the food herself, works out at roughly from 2d. to 4d. a day for a young infant.

Chemical Composition of one of the Samples known as "Full Cream," together with a Dilution of 1 to 7 with Water, Compared with Cow's Milk and Human Milk:

	Dry Powder.	Diluted 1 in 7 Water.	Cow's Milk.	Human Milk.
Milk proteins	22.2	2.7	3.7	1.5
Milk sugar	41.0	5.1	4.7	6.8
Butter fat	27.4	3.4	3.7	3.3
Salts	5.9	0.7	0.7	0.2
Moisture	3.5	88.1	87.2	88.2
Total solids		(11.9)	(12.8)	(11.8)

As will be seen by the above, dried milk diluted with water, 1 part to 7, nearly approximates to human milk as regards fats and sugar, the proteins and salts in lesser degree; when it is remembered that the composition of cow's milk may vary considerably in different samples—the fat alone varying from a minimum of 1.9 per cent. to a maximum of 6.9 per cent., and the total solids from 10 per cent. to 16 per cent.—the advantages of having a food with a definite chemical composition, which is always constant, is very great.

Acidity of Samples Examined.

Dried milk A, 10% sol. ...	100 c.cm. = 6.8 c.c. N/10 NaHO sol.
Dried milk B, 10% sol. ...	100 c.cm. = 4.4 " "
Samples of ordinary milk taken:	100 c.cm. = 17 to 20 " "

The ash of the dried milk Sample B after incineration gave no effervescence with HCl, nor could any evidence of the presence of boracic acid be detected.

With regard to the feeding value of dried milk, if the calorific value of its protein, fat, and carbohydrate are worked out as such, a child, for instance, of, say, 10 lb. weight being fed every two hours during the day and two feeds at night would have sufficient calorific energy at its disposal to satisfy its requirements and a very liberal margin of nearly 200 foot tons to spare daily, the amount varying according to whether Voit's, Clittenden's, or another scale is taken as the standard.

The curds produced by solutions of the dried milk are extremely small, and vary slightly in consistence as to the kind of milk used, whether "half" or "full cream."

Experiments conducted with rennet as regards the clotting capacity gave the following results:

A sample of boiled cow's milk with rennet=	thick solid curd.
" unboiled "	= large heavy curds.
" dried milk solution—1-7 (B) "	= very small curds.

I also frequently examined the faeces of the infants fed on the dried milk, but could not detect any curds except in the case of the child suffering from diarrhoea, which was of the lenteric variety. Probably the citric acid, etc., in the fruit juice was largely responsible for the absence of curds; unfortunately I did not do a control feeding without the fruit juice.

The Bacteriology of Infantile Diarrhoea in Relation to Milk Feeding.

The following amoebae and bacteria have been isolated from the faeces of children suffering from this complaint: Amoebae, including *Paramoecium coli*, *Sarcomonas intestinalis*, and *Amoeba coli* (as far as I am aware, very little work has been done on these organisms, therefore I have neglected them), together with the moulds, etc., such as *Oidium albicans*, *Aspergillus glaucus*, *Penicillium glaucum*, and *Mucor mucedo*. The principal bacteria which have been isolated from the stools of children suffering from diarrhoea are noted below. Whether the diarrhoea is produced by the lactic acid fermentation caused by many of these organisms, or by direct absorption of toxins from the alimentary canal, is still a debated point. A brief glance at the actions of the commoner bacteria associated with infantile diarrhoea, on milk under laboratory conditions—that is, incubated at 37° C.—may be of interest.

B. coli forms acid, gas, and firm clot in litmus milk; it also ferments lactose, forming acid and gas.

B. dysenteriae turns litmus milk first acid and later alkaline, and does not ferment lactose.

B. enteritidis (Gaertner) usually turns litmus milk alkaline and does not affect lactose; but different strains of the bacillus act differently.

B. enteritidis sporogenes gives a very characteristic reaction with litmus milk. First, a large clot is formed; later this is broken up by the abundant gas formation, and an almost perfect separation into curds and whey takes place; the latter is acid, and swarms with the bacilli. As this organism is spore-bearing it would not be destroyed by pasteurization or raising to boiling point only, but apparently it is destroyed by the drying process.

B. butyricus (Bodkin) was isolated by Klein in 1895. It ferments lactose, forming acid and gas.

Thermophilus No. 1 bacillus with litmus milk slowly gives alkaline reaction, does not change lactose, but with galactose forms acid and gas. It produces fatal diarrhoea in rabbits, rats, and monkeys fed on food contaminated with cultures of it.

Looking at the foregoing list of organisms, and their actions on milk, the staple diet of infants, it is at least feasible to assume that, presuming they are not present in the intestine (except, of course, *B. coli*, which is always present), the use of a sterile food during the diarrhoea season must be advantageous.

Even assuming the absolute necessity of symbiosis, as held by many authorities, there are plenty of organisms having their normal habitat in the intestine without introducing fresh ones of a highly pathogenic nature through the medium of filthy milk.

With reference to the weight increase, as previously mentioned, from 4 oz. to 6 oz. weekly, I think, it was not bad when it is remembered that none of the infants were normally healthy or well cared for. All were collected from the out-patient departments, all were children of the poorest and most neglected class; and all were suffering from one or other of the various ailments so common amongst this class of children, principally bronchitis, bronchopneumonia, marasmus, and in some cases diarrhoea, but the latter were, of course, not included in the report as to the incidence of same during the feeding, but a record kept only of their increase in weight after the diarrhoea had ceased.

Summary.

The trial lasted nineteen weeks altogether, during which 38 infants were supplied with the food gratis, and fed solely on it.

The length of time during which the children were under observation varied, some being brought up regularly every week for the whole time, and these did the best; on the other hand, others were only brought up for a week or two, and then were not seen again owing to the slackness of the mothers, or, perhaps, because they were too busy to spare the time to bring the children to the dispensary. During the whole period we had 5 cases of diarrhoea, but as 2 came to us already suffering from the complaint, and 2 contracted it at times when they were not being fed by us—that is to say, they ran out of food, and instead of coming up at once for a fresh supply the mother fed the infants for about a week on such substitutes as boiled bread and water, condensed milk, etc.—it is only fair to exclude these also. The only case I cannot account for is that of a child who was fed on dried milk solely from start to finish, and had an attack of diarrhoea lasting two days during that time. A careful bacteriological analysis of the faeces failed to demonstrate the presence of any organisms usually associated with epidemic enteritis; I am of the opinion that the attack may have been purely accidental, especially as it lasted such a short time, and the child did not lose more than 4 oz. in weight during the attack.

In conclusion, I am of opinion that dried milk is deserving of further trial during the summer months when epidemic enteritis is so prevalent, especially amongst the poorer classes, and, if prepared as indicated, it is a food which if not absolutely sterile is very nearly so.

Appended is the result of the bacteriological analysis both of the solution of dried milk prepared as directed, and also of a sample of ordinary milk after pasteurization. I would desire to acknowledge my indebtedness to my chief, Dr. Eyre, for his kind supervision; also to my colleagues, Messrs. Leeming and Ryffel, for their kind assistance. As unfortunately one supply of dried milk was sent me in a cask a bacteriological analysis was only possible of sample "B," which was sent out in sealed tins. A solution in sterile water smeared on the surface of nutrose agar failed to give a growth in seventy-two hours after incubation at 37° C.

Bacteriological Analysis of Sample B Dried Milk.

Ten grams were weighed into a sterile flask and made up to 100 c.cm. with sterile water and used for analysis.

Number of organisms growing on gelatine plates and capable of multiplying at 20° C. after six days, 200 per c.cm.

Organisms on agar plates cultivated at 37° C., 0 per c.cm.

"Microbes of indication":

<i>B. coli communis</i> ...	absent from 1 c.cm.
<i>B. enteritidis</i> (Gaertner) ...	" " "
<i>B. enteritidis sporogenes</i> ...	" " "
<i>Streptococcus faecalis</i> ...	" " "

No tubercle or diphtheria bacilli could be detected.

A few moulds developed on the plates, but were probably only indicative of aerial contamination; 50 c.cm. were centrifuged in a high-speed machine, and both cream and deposit examined microscopically and culturally for organisms, but none were detected. A few leucocytes only were observed in cream and deposit.

A sample of ordinary cow's milk was subjected to pasteurization for twenty minutes at 75° C., and after straining through four thicknesses of sterile butter muslin into a sterile flask, gave the following result on analysis:

Organisms growing on gelatine plates at 20° C., 70,000 per c.cm.
Organisms growing on agar plates at 37° C., 600 per c.cm.

Cream and deposit after centrifugalizing examined microscopically:

Cream:	Streptococci	}	present
	Staphylococci		
	Epithelial and pus cells		
Deposit:	Streptococci	}	present
	Staphylococci		
	Epithelial and pus cells		

Cultures on blood serum of creams and deposits showed the presence of a large Gram-positive, spore-bearing bacillus, probably *B. subtilis*, only (not inoculated or investigated further).

Specific examination after pasteurization—

<i>B. coli communis</i> absent from	...	1 c.cm.
Klebs-Loeffler bacillus	...	1 "
<i>B. enteritidis</i> (Gaertner)	...	1 "

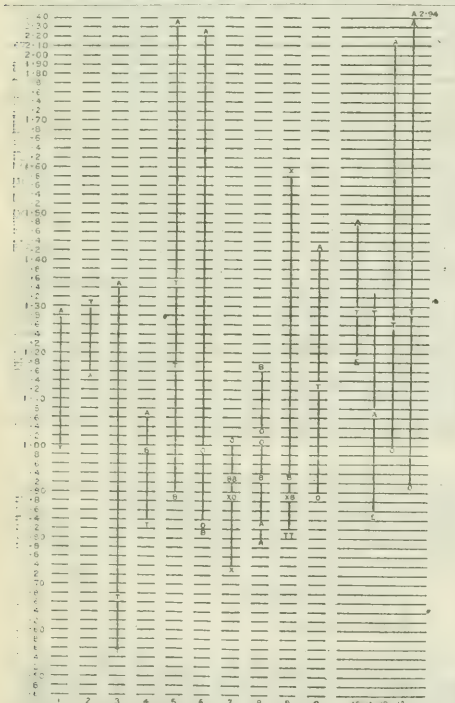

No tubercle or diphtheria bacilli were detected in cream or deposit.

CAN OPSONIC ESTIMATIONS BE RELIED ON IN PRACTICE?

By E. C. HORT, B.A., B.Sc. UNIV. PARIS, M.R.C.P. EDIN.

It frequently happens in hospital practice and in private that a reliable method of diagnosing difficult cases of infection is urgently needed. In no disease is this more true than in tuberculosis. For general use, where ordinary methods fail us, the cutaneous methods of von Pirquet, Moro, and Wolff Eisner, including Calmette's modification of these by conjunctival instillation, are not of pre-eminent value. In private practice the dangers and fallacies of

Chart showing Different Opsonic Indices of Identical Serums, as Estimated by Different Observers.

Calmette's test effectually bar its universal acceptance. Of Professor Courmont's modification of the serum diagnosis of tuberculosis there are not as yet sufficient data to judge. In this country, and in America, it is widely believed that in the opsonic index we have at last a method which is trustworthy not only for diagnostic purposes, but also for prognosis, and in determining treat-

ment. After extensive trial of its merits, mainly in tuberculosis, over a period of three years, I am not able to endorse the view that the index is a safe guide to diagnosis and treatment, even when estimated by acknowledged masters of the opsonic art.

In order to test its value as presented to us to-day, I have from my own private practice taken a series of cases, some of which had been sent for diagnosis, and in whom a trustworthy opinion, apart from physical signs, was therefore of real importance. No sort of selection has been made, and results that favour the opsonic method of estimation have been impartially recorded side by side with the unfavourable ones. In all cases the nature of the test has been explained to the various observers, who have without exception encouraged the inquiry. One observer, indeed, expresses the hope that the tests will be published in order to stimulate further efforts in improving the technical details. Such devotion to the highest traditions of scientific research cannot but command our admiration. Each observer mentioned in the accompanying chart is the same throughout, and is designated always by the same letter. It is, perhaps, unnecessary to say that only experts with years of practice and only those directly connected with well-known laboratories have been asked to examine the various serums supplied. In each of these twelve cases two or more samples of serum drawn at the same time and under precisely similar conditions, have been sent to two or more workers, sometimes in the same laboratory, sometimes in different laboratories. In addition to this, as will be seen, occasionally two samples of the same serum have been sent to one observer, who was not informed that they were samples of identical serums.

In each case the following precautions were taken:

1. Whether taken from vein, finger, or ear, the serum was separated from the clot at the end of six hours after puncture of skin or vein.
2. No serum was estimated unless quite free from contamination from red cells.
3. In sealing the tubes all possibility of heating the serum was obviated by using tubes with long drawn ends.
4. All tubes were sealed within five minutes of collection.
5. All indices were estimated within twenty-four hours of collection.
6. All samples of each batch of serum were taken from blood provided by one bleeding, in most cases by venipuncture.

TESTS 1 AND 2.

Disease suspected: renal tuberculosis.

A dose of 100 mg. T.R. tuberculin was administered by the mouth and the indices to tubercle bacillus were estimated by two observers in different laboratories, both before and after inoculation. The interval between the two sets of observations was fifteen hours. The indices returned were:

Before Inoculation.			
Observer A.	O.I. to T.B. ...	1.29	Phagocyte count not kept
Observer T.	" " " " " "	0.97	" " " "

After Inoculation.			
Observer A.	O.I. to T.B. ...	1.15	Phagocyte count not kept
Observer T.	" " " " " "	1.30	" " " "

In this case observers A. and T. differed in their estimation of the index after inoculation by 0.15, a small difference. Before inoculation they differed by 0.32, a not inconsiderable difference. Further whilst A. estimated that inoculation was followed by a fall of index, Observer T. registered a rise. Two indices were within normal limits and two outside it.

TESTS 3 AND 4.

Disease suspected: tuberculosis, position of focus unknown.

In this case there was no direct evidence of any organ being directly the seat of tuberculous infection, but in view of anomalous pyrexia it was necessary to exclude, if possible, such a contingency. Two series of observations were therefore undertaken with a week's interval. In the first test two samples of the same serum were sent to one observer, and a third sample was sent to a second observer in a different laboratory.

The indices returned in the first test were:

Observer A.	O.I. to T.B. ...	1.34	Phagocyte count not kept
Observer T.	" " " " " "	0.67	" " " "
Observer T.	" " " " " "	0.55	" " " "

In the second test three tubes of the same sample of serum were sent to three observers in three laboratories a week after the first test.

The indices returned were:

Observer A.	O.I. to T.B. ...	1.06	Phagocyte count not kept
Observer B.	" " " " " "	0.98	" " " "
Observer T.	" " " " " "	0.82	" " " "

In the first test the maximum variation was 0.79, the minimum 0.12, and the middle variation 0.67. Observer T. differed from himself by 0.12. In no case was the index within normal limits.

In the second test the maximum variation was 0.24, the next largest 0.16, the minimum 0.8. In no case was the index outside the normal limits.

TEST 5.

Disease: pulmonary tuberculosis, with well-marked physical signs, fever, and tubercle bacillus in the sputum.

Four tubes of the same sample of serum were sent to three observers in three different laboratories. To Observer T. two tubes of the same serum were sent without his knowledge. The indices returned were:

Observer B.	O.I. to T.B.	0.88	Phagocyte count of 100 cells, 211	240
Observer T.	"	1.17	Phagocyte count not kept	
Observer T.	"	1.34	"	"
Observer A.	"	2.34	"	"

The maximum variation here was 1.46, the next largest 1.17, and the minimum 0.17, the figure by which Observer T. differed from himself. In this case two indices were within normal limits and two above.

TEST 6.

Disease suspected: military tuberculosis. In this case the patient was extremely ill with high fever, but the physical signs in the lungs were anomalous.

Four tubes of the same serum were sent to three observers in three different laboratories, two tubes of identically the same serum being given to Observer O. without his knowledge. The indices returned were:

Observer A.	O.I. to T.B.	2.20	Phagocyte count not kept	
Observer O.	"	0.96	Phagocyte count of 100 cells, 126	130
Observer O.	"	0.82	"	107
Observer B.	"	0.82	"	193

In this case the index returned by B. was practically identical with one of the indices returned by O., who differed from himself by 0.14. The maximum variation between A. and B. was 1.40. In a case almost certainly tuberculous clinically of four observations only one was outside normal limits.

TEST 7.—Serum from Normal Individual.

In this case six samples of the same serum were sent to three observers in three different laboratories, each observer receiving unknown to him two samples of the same serum.

The indices returned were:

Observer X.	O.I. to T.B.	0.72	Phagocyte count of 100 cells, 202	
Observer O.	"	0.87	"	222
Observer B.	"	0.92	"	231
Observer B.	"	0.93	"	232
Observer X.	"	0.89	"	249
Observer B.	"	1.07	"	288

In this case B.'s observations were practically identical, and were very close to single observations of O. and X. The latter, however, differed from himself by 0.17, and O. differed from himself by 0.20. The maximum variation also was considerable—namely, 0.35. The fact, however, that all observers returned an index within normal limits is striking.

TEST 8.

Disease suspected: renal tuberculosis. In this case there was present, in addition to the signs incriminating the left kidney, a large inflamed tuberculous cervical gland undergoing rapid softening. Massage of the kidney was undertaken, and the opsonic indices were estimated before and after massage. In each case six samples of the same serum were sent to six observers in five different laboratories, each observer receiving, unknown to him, two samples of the same serum. Observer B. alone was given tubes before and after massage.

The indices returned were:

Before Massage.				
Observer A.	O.I. to T.B.	0.78	Phagocyte count of 100 cells,	—
Observer A.	"	0.83	"	"
Observer B.	"	0.85	"	193
Observer O.	"	1.00	"	228
Observer O.	"	1.03	"	233
Observer B.	"	1.17	"	245

After Massage (Twenty Hours)

Observer T.	O.I. to T.B.	0.81	Phagocyte count of 100 cells, 227	281
Observer T.	"	0.82	"	229
Observer B.	"	0.89	"	220
Observer B.	"	0.93	"	232
Observer X.	"	0.89	"	246
Observer X.	"	1.59	"	443

In this case some of the results are remarkably consistent. Observer A. differs from himself by only 0.05, Observer O. by only 0.03, Observer T. by only 0.01, and Observer B. returns an identical index before and after massage of 0.95. On the other hand, the value of this unanimity is upset by the maximum variation before massage, 0.39, and a maximum variation after massage of 0.78. Again, whilst B. returns an identical index before and after massage, his second reading gives a drop after massage of 0.24, the difference between his first two observations. Further, Observer X. is seen to differ

from himself by 0.70. In conclusion, it is worth noticing that in a case obviously tuberculous only two indices were returned as being outside the normal limits, one being 0.02 below and the other 0.39 above.

The interval between the two sets of observations was twelve hours.

TEST 9.

Disease suspected: pulmonary tuberculosis.

In this case three samples of the same serum were sent to three observers in two laboratories.

The indices returned were:

Observer A.	O.I. to T.B.	1.42	Phagocyte count of 100 cells, 95	67
Observer T.	"	1.02	"	180
Observer O.	"	0.95	"	178

Here A. differed from O. by 0.47. The next largest variation was 0.40, and the smallest 0.7. Two indices were well within normal limits, and one much above.

TESTS 10, 11, 12, 13.

Disease suspected—pulmonary tuberculosis. Moderate fever.

In this case, on three successive days three samples of identical serums were sent on four different occasions to three different observers.

The indices returned were as follows:

11.30 a.m. first day:				
Observer A.	O.I. to T.B.	1.48	Phagocyte count of 100 cells, 136	92
Observer T.	"	1.28	"	90
Observer E.	"	1.18	"	159

6 p.m. first day:				
Observer A.	"	1.6	"	147
Observer T.	"	1.28	"	230
Observer E.	"	0.81	"	113

6 p.m. second day:				
Observer A.	"	2.16	"	145
Observer T.	"	1.26	"	221
Observer O.	"	0.95	"	178

6 p.m. third day:				
Observer A.	"	2.94	"	197
Observer T.	"	1.28	"	—
Observer O.	"	0.92	"	—

It is of interest to note that the temperature at the times when the various sets of observations were made were as follows:

First Set.	Second Set.	Third Set.	Fourth Set.
99.6	100.6	100.2	99.0

The observations of Observer T. were remarkably consistent, being on all four occasions practically identical. The maximum variations of T. from A. on each occasion were, however, 0.20, 0.32, 0.90, 1.66. The maximum variation in all the observations was 2.02.

That opsonins do exist as factors to be reckoned with appears to have been firmly established by Sir Almroth Wright and his many followers. That they represent more than a fractional part in the highly complex machinery of immunity production we may still be permitted to doubt. Granted, however, for the moment, that opsonins are the important factor in the phenomenon of immunization that many believe them to be, the question at the head of this paper is constantly arising. Technical considerations of standardization of emulsions, cultural difficulties, agglutination questions, and so forth concern only those experts whose responsibility it is to render such technicalities as free from sources of error as possible. They do not affect the practising physician, whose only concern is with the pertinent questions of reliability and cost. As regards cost, as every one knows, it is high and necessarily so, and a most serious objection to wide use of the method it is. Regarding the question of reliability, it is quite impossible to ignore the fact that countless observations have been reported in which estimations have appeared to be of the highest value, either in diagnosis, or in directing some particular line of treatment. This is by no means, however, a universal experience, even when every effort has been made to secure the services of the high priests of the art. There appears, indeed, to be a growing conviction that, except possibly in the hands of an extremely small band of experts, the method is not of the general utility with which it has been credited.

The results I have quoted seem to support this conviction. If there is a satisfactory answer to these results, no doubt it will be forthcoming.

I take this opportunity of acknowledging my indebtedness to Dr. A. Venning for continuous help in the collection and separation of the serums referred to.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

IMPERFORATE PENILE URETHRA: COMPLETE OCCLUSION OF MEATUS.

On January 31st I attended a lady at the delivery of her sixth child. Labour was perfectly normal, and the child was a healthy male weighing 9 lb. 6 oz. When I visited my patient two hours later, the nurse informed me that the infant's penis was "tied down underneath." I found that there was no meatus at the end of the penis, nor any urethral orifice further back. The condition otherwise simulated hypospadias, and the scrotum, divided into two folds, presented the appearance of a pair of labia, which suggested hermaphroditism. The integuments of the dorsum of the penis were hypertrophied, and hung like an apron over the glans, which was perfectly formed. I made a careful dissection of the glans at the site of the meatus, and to my great relief urine gushed out when my incision had reached the depth of $\frac{1}{2}$ in. I had, in fact, opened the blind end of an otherwise perfect urethra. The child now passes urine without any difficulty through the artificial opening, and is a fine, healthy, well-developed infant, progressing favorably. The parents and their other children are perfectly healthy.

St. Albans, Herts.

JOHN HOBBS, L.R.C.P. and S.Irel.

[This condition is uncommon. For extreme cases see Professor Arthur Keith, "Malformations of the Hind End of the Body." Lecture II, *Healing Imperforate Penile Urethra*. JOURNAL, December 19th, 1908, p. 1507; also Shattock, "Imperforate Urethra in a Fetus of about the Fourth Month," *Trans. Path. Soc.*, vol. xxxix, 1888, p. 185. "Occlusion most frequently occurs between the triangular ligament and the glans, and often the whole of this tract is affected" (Keith). Our correspondent will bear in mind that (1) patent urachus is always possible when a male infant is born with any mechanical obstruction to micturition, so that he may find that in his case urine will leak from the umbilicus if the bladder be allowed to become distended, but that this symptom usually develops after infancy. (2) Hermaphroditism is quite probable in this case. The testes may be undescended, and even there be one or both genital glands in the scrotum one or both may ovaries. In respect to the surgery of congenital occlusion of the meatus Duplay's advice should be followed. The incision through the line of atresia should be followed by the introduction for several days of a large bougie, which need only be passed for a short distance into the urethra; otherwise cicatricial contraction may advance to such an extent as to interfere with micturition and to involve well-known vesical complications.]

INVERSION OF THE UTERUS.

Dr. A. W. HOLTHUSEN's interesting case of acute inversion of the uterus following delivery recalls to my mind a similar case with which I had to deal about three years ago.

On April 4th, 1906, I received an urgent message from a neighbouring practitioner to come and assist him in a confinement case. I found the patient pale and collapsed; there were signs of profuse hemorrhage, and the uterus was completely inverted and lying outside the vulva. My colleague explained that he had only arrived at the house about ten minutes before me in response to a call from an untrained midwife of the Gamp type, and found the patient in the condition described; he had just had time to peel the placenta off the inverted uterus. At his request I made an immediate attempt to replace and reinvert the organ. The patient was lying on her left side in a state of extreme shock, with a barely perceptible pulse and shallow respiration. I gripped the displaced organ with my left hand and pressed it steadily upwards. The vagina and cervix were readily dealt with, but considerable difficulty was experienced in reinverting the body and fundus of the uterus. Having pressed the fundus through the os, I used the closed fist of my left hand while steadying the abdominal walls with the right. After a little manipulation the fundus was at last pushed back to its proper position. There was no recurrence of the inversion. As, however, the patient remained in a collapsed condition, it was decided to resort to saline infusion. In the absence of more suitable apparatus, an antitoxin syringe was used for this purpose, and a pint of the salt solution injected into the subcutaneous tissue

between the scapulae in repeated doses. Some strychnine was also given hypodermically, and stimulants were administered by the mouth. The patient revived considerably, and was left to the care of her friends, who were instructed to keep her very quiet.

I did not see the patient again until three weeks later, when she walked into my surgery carrying her baby. She complained of some pain in her back and attacks of dimness of vision, but otherwise felt well. I was subsequently told by her medical attendant that her recovery was uninterrupted. I have recently ascertained that the woman has had another child since, and that labour was in every way normal. At the time of the inversion the patient, whose age was 22, was going through her second confinement. Nothing special occurred on the first occasion. There was a strong suspicion in this case that the inversion was the result of traction on the umbilical cord by the midwife, but this was strenuously denied. The latter stated, however, that the cord was twisted round the child's neck when it was born.

London, E.

EDMUND HAY.

HERPES OF THE SECOND AND THIRD CERVICAL POSTERIOR ROOT AREAS, ACCOMPANIED BY FACIAL PARALYSIS.

As motor paralyses accompanying herpes zoster are comparatively rare, the following case is of some interest.

On October 27th, 1906, the patient, a man aged 50, noticed "a few little pimples" above the left ear and behind the ramus of the jaw, and in the occipital region on the left side. Between this day and October 30th the eruption developed fully, consisting of vesicles, some of large size, on an erythematous base. There were no premonitory symptoms, and no definite pain was complained of during the development of the rash, only a little aching of the face. The pulse-rate was quickened and the temperature a little raised.

As seen by me on November 1st, the distribution of the eruption was as follows:

1. Below, it extended to the clavicle.
2. Above, to some distance above the ear, over the lower parts of the parietal and occipital bones. A few scattered vesicles extended forwards almost to the temporal crest of the frontal bone.
3. Anteriorly, on the face it extended to about the anterior margin of the ramus of the jaw as low as the angle of the mouth, and on the neck it extended to the middle line.
4. Posteriorly, it extended to the middle line of the neck and lower part of occipital bone.

This distribution comprises, as I understand, the second and third cervical posterior root areas of Head, though I have not been able to find diagrams illustrative of the area supplied by the second cervical posterior root, herpes of this area being invariably associated with herpes of the third cervical root area. There were also a small isolated patch over the second left chondro-sternal articulation, and two or three isolated vesicles just below the left ala nasi.

The crop of vesicles was most abundant over the whole length of the sterno-mastoid muscle, especially behind the ear. On the ear itself there were a few scattered vesicles.

On October 30th, when the eruption was at its height, the face was noticed to be swollen on the left side, and the lower eyelid to be puffy.

On November 3rd well-marked paralysis of the left side of the face showed itself. The mouth and nose were drawn to the right side, the left eye could not be closed, the left eyebrow drooped whilst the right was drawn up, and he laughed and frowned with the right side of the face only.

On November 13th there remained of the eruption only the erythema, but recently the patient had begun to complain of severe pain at times, especially at night, about the neck and jaw.

The patient was a very unhealthy subject, badly nourished, and deformed by very pronounced lateral curvature of the spine, and in addition showed distinct physical signs of tuberculous disease of both lungs, a condition to which Dr. Head alludes in his article in *Alburt's System* as frequently associated with herpes.

Bristol.

E. WATNERHEAD.

THE RADICAL TREATMENT OF ELEPHANTIASIS.
In the JOURNAL of October 31st, 1908, containing the paper and discussion on the treatment of elephantiasis, there is but scant mention of the radical treatment of this disease as affecting the extremities. Sir Havelock Charles makes some complaint that Indian clinical experience takes a long time to permeate to writers in England, but judging from his further remarks, where he refers to his having removed the affected tissues from the knee to the toes, etc., and that Major Stevens, he believed, had very successfully practised the same, it would appear that our Madras clinical experience has taken a long time to permeate to Calcutta.

The first operations of this kind ever performed in India were performed by me in Madras at the Royapetta Hospital, and subsequently the operation was practised a considerable number of times both by myself and various colleagues at the General Hospital, Madras. My early cases were published in the proceedings of the South Indian Branch of the British Medical Association. The Director-General, Indian Medical Service, of the time, when visiting Madras, saw some of my earlier cases: the procedure was new to him. I mentioned the operation to the then surgeon to the College Hospital, Calcutta, and his reply showed that it was new to him also. Sir Jonathan Hutchinson, when touring in India, also saw some of my cases.

So many surgeons have had a hand in bringing the technique of the radical operation for scrotal elephantiasis to its present high state of perfection that no surgeon or group of surgeons can claim priority; but in the matter of the radical operation on the extremities I do claim priority for Madras. Experience has shown that the operation in selected cases is sound and justifiable. I use the term selected advisedly; it would take too long here to go into the advantages and disadvantages of the operation. Suffice it to say that in those cases in which the limb has attained such dimensions that the mass interferes seriously with progression—cases in which in former times amputation has been performed—the operation under notice is to be recommended.

ANGINA.

RECENT physiological experiments (Schäfer, Oliver-Sharpey Lectures, April 9th, 1908) show that the coronary arteries differ from the systemic in the matter of the contractility of their walls. It has been generally recognized, and it is demonstrated by Schäfer and Legendorff's experiments, that the coronary arteries are little, if at all, controlled by vaso-motor muscle.

The absence of contractile power from the coronary arterial wall distinguishes these vessels from the vasa vasorum of the aortic wall. For since intravascular tension determines vaso-constriction in systemic arteries, the volume of blood circulating in the nutrient arterioles of the aortic wall is in an inverse ratio with the lateral pressure of the aortic stream, while the volume of blood in the nutrient arterioles of the cardiac wall is in a direct ratio. Therefore, during periods of high blood pressure, the influences at work upon the aortic wall are katabolic, while those at work upon the cardiac wall are anabolic. It follows that hypertrophy of cardiac muscle keeps pace with the circulatory requirements necessitated by advancing peripheral resistance, while hypertrophy of aortic muscle, if occurring at all, does not keep pace with these requirements.

In other words, while the normal ratio existing between the lateral pressure of the blood stream and the resistible capacity of the containing wall is maintained in the case of the ventricle, it becomes altered in the case of the aorta, and the walls of this vessel are rendered liable to strain.

The difference existing between the coronary arteries and the vasa vasorum of the aorta in the matter of their respective contractile powers thus affords an intelligible explanation of the pathological conditions underlying the symptoms of angina.

Moreover, since vaso-constriction is a protective action, the absence of it during periods of increased aortic

pressure lays the coronary arteries open to strain and to diseases resulting from strain. Consequently the atheromatous and ossified state of the tissues of this artery, frequently observed in the subjects of angina after death, is to be regarded as a direct result of increased blood pressure, and as a concomitant condition rather than as a cause of angina.

London, S.W.

WALTER VERDON, F.R.C.S.

GLOSSINA MORBITANS AND SLEEPING SICKNESS.

THE following brief note may be of interest in the consideration of the question as to whether *Glossina morsitans* may or may not be capable of conveying *Trypanosoma gambiense* in the same manner as *Glossina palpalis*.

During a recent investigation of the conditions obtaining in the northern part of the Katanga I was able to make the following observations:

1. Of natives who were living in villages in the vicinity of which neither *G. morsitans* nor *G. palpalis* was found—

233 men showed 17 cases of infection.
118 women showed no cases.
83 children showed 2 cases.

Thus of 434 natives 3.9 per cent. were infected.

2. Of natives who were living in villages in the immediate vicinity of which *G. morsitans* was to be found but not *G. palpalis*—

844 men showed 37 cases of infection.
372 women showed 1 case.
259 children showed 2 cases.

Giving a percentage of infection for 1,475 natives of 2.7.

3. Of natives who were living in villages in the immediate vicinity of which *G. palpalis* was to be found—

572 men showed 75 cases.
254 women showed 34 cases.
200 children showed 11 cases.

Giving a percentage for 1,026 natives of 11.7.

These figures show clearly that there is absolutely no evidence that the infection has spread more rapidly amongst those villages which are situated in *morsitans* areas than amongst those which are free from the presence of this fly.

The routes which are in common use amongst the natives in this part of the country pass through both *palpalis* and *morsitans* areas, though the former are very much smaller than the latter.

If *G. morsitans* is to be reckoned alike with *palpalis* as a transmitter of the disease, we should expect to find that the villages situated in *morsitans* areas would show at least as heavy a percentage infected as those in *palpalis* areas. For it is to be remembered that natives are surely bitten in this country one hundred times more often by the former than the latter fly.

These figures, however, show that the *palpalis* villages are far more more heavily infected than the *morsitans*, and the comparison becomes still more strongly marked if we eliminate the travellers—namely, the men—and consider the women and children, who represent more fairly the effects of the bites of the fly in the vicinity of the village. In every case where women or children were found to be infected in *morsitans* villages they had recently arrived at the village from some endemic area.

When it is borne in mind that trypanosomiasis has certainly been present to some degree in that country for three or four years, and that it is impossible in most parts for travelling natives to avoid being bitten hourly by the *morsitans*, it would seem impossible that no more evidence would have come to hand if this fly had been able to carry the infection.

It is, perhaps, wise to add that the part of the country from which my observations have been drawn is situated far to the north of the Katanga copper belt, and that the systematic inspection of natives entering the mineral belt from all quarters has revealed no single case of infection from the area referred to for the past four months.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

Friday, January 22nd, 1909.

T. H. MILROY, M.D., President, in the Chair.

Reaction Time.

THE PRESIDENT said he wished to put before the members the result of some work which he had done on reaction time, and which he had undertaken in order to study the nature of mental fatigue. By reaction time was meant the period which elapsed between the initiation of a sensory stimulus and a volitional motor response on the part of the stimulated individual. One might estimate this time for hearing, sight, or touch, taking the same type of motor response as indicator in each case. When a series of reaction times was taken for any of the above-mentioned senses, it was observed that there were naturally distinct variations in the intervals between the sensory stimuli and the motor responses; but it might also be observed that in all cases, after a prolonged series had been taken, fatigue gradually sets in, as shown by a lengthening of the reaction time. This fatigue might affect the sensory paths, the sensory centres, the intermediate central paths between these centres, and the voluntary motor centres, or the motor path as far as the muscles themselves. In all cases a preliminary series of reaction time experiments was made in order to obtain an average normal result. Then, following such a series, various devices were employed in order to fatigue mainly the sensory, then, in another series, mainly the intermediate central paths, and in still another, the motor paths. From a careful study of a large number of experiments on the reaction time, it appeared as if in all cases the fatigue had its seat in the higher centres concerned in the direction of the attention towards the sensory motor reaction. These higher centres appeared to be required in order to link the various synapses of the higher physical and volitional motor centres more closely together, and thus facilitate the transmission of the nervous impulses. Thus, in their fatigue there was a delay in transmission, probably due to the higher resistance at the synapses, which were not so closely linked together as when the attention was freshly directed towards the act at the outset of the experiment.

After remarks by Professor DIXON, Professor FRASER, and Dr. DAWSON,

Dr. WALTER SMITH said that, in judging of reaction time, an important factor was the duration of the stimulus. There was a great difference between the momentary impact of a visual stimulus and the relatively long duration of even the shortest sound. The subject was valuable to physicians and surgeons in estimating the phenomenon of knee-jerk, or the many manifestations of disordered and delayed sensations in hysteria. A most important point was the fatigue in the synapses between neurones. It was possible to draw an analogy between mental and digestive processes. In the nervous system they might recognize the possibility of a stimulus of stimuli just as there was in the digestive system a ferment of ferment.

Dr. MOORHEAD said he strongly believed that after a short rest following work one could turn to a new variety of work that required just as much attention, whereas if one turned to the same kind of work the same power of attention would not be appreciated.

THE PRESIDENT, in reply, said the nature of impressions varied according to the stimulus. One's idea of certain sounds was based on past sensations and memories which called forth a different mental condition. There were certainly two paths between neural centres, one voluntary, the other formed by habit, but they could not say whether the linkage was always made by the one path, nor could they recognize where volition came in. His tests were for the purpose of finding where fatigue occurred, not to find what alterations in duration of stimuli produced—that had been carefully worked out by others. It was difficult to tell how change gave rest. Sight plus hearing would produce greater fatigue than one form of fatigue carried the whole way down.

The Sterno-clavicular Joint.

Dr. H. M. JOHNSTON presented a communication on this joint, and exhibited drawings. The security of the joint was shown to depend mainly upon the costo-clavicular ligament, which was always tense, even when the upper extremity was hanging by the side. Owing to the attachment of this ligament to the clavicle being on the posterior-inferior aspect, elevation of the clavicle was permitted by a movement of rotation taking place, during which the anterior surface of the bone became directed somewhat upwards. The interarticular meniscus, intervening between the inner end of the clavicle and the sternum and first costal cartilage, and against which, owing to the laxity of the capsular ligament, the articular surface of the clavicle could move (upwards and downwards, forwards and backwards), serves rather as a "buffer," preventing shocks and jars being transmitted to the sternum, than as a ligament. To the sternum and costal cartilage (this meniscus intervening) the inner end of the clavicle seemed to be, as a general rule, firmly applied. During pulling, and when supporting the weight of the body by hanging from the hands, the clavicle was drawn somewhat outwards. This did not occur during reaching movements, as the contraction of the subclavius muscle prevented the clavicle being drawn away from the sternum as the scapula moved outwards and forwards.

Professor DIXON stated that he had seen the dissections made by Dr. Johnston, and was convinced that the explanations given of the function of the costo-clavicular ligament and of the subclavius muscle were the correct ones.

Specimens.

Professor McLOUGHLIN exhibited a specimen of *Dorsal subclavian artery* and one of *Duodenal diverticulum*.

Lantern Demonstration.

Professor FRASER gave a lantern demonstration of a series of slides showing (a) the living model from the front, the back, and the side, with the superior extremity in various positions; (b) a series of the head and neck, showing the various movements—flexion, extension, lateral inclination, and rotation to right and left; (c) a series of the trunk, showing its various movements—flexion, extension, lateral inclination, and rotation to right and left; (d) a series of the lower extremity, showing the various degrees of flexion from the outer and inner aspects of the limb.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—At a meeting on Wednesday, February 3rd, Dr. G. A. GIBSON and Dr. W. T. RITCHIE read a paper on a historical instance of the *Adams-Stokes syndrome due to heart-block*. A distinguished physician had enjoyed during a long life very excellent health, excepting that during his youth some suspicion had been aroused by the condition of the lungs, which led to his spending a winter in Rome, immediately after graduation. In 1899, being then 75 years old, he had a serious attack of influenza, and in the following year he retired from the positions which he occupied, and settled in Edinburgh. Until his house was ready he lived in one of the suburbs, and used to go backwards and forwards by train. In September, 1900, when in the train going into Edinburgh, he was suddenly attacked by unconsciousness and muscular rigidity. He was seen shortly afterwards by Professor Wylie and Dr. Gibson, and the condition was then found to be one of great prostration. Consciousness had returned, but the patient was very dull and listless. The pulse at the wrist was only 6 per minute, the apex beat being the same, and there were no missed beats. The first sound was quite distinct, and was followed by a clear, ringing second sound, but between these were other feeble sounds (to be referred to later). In the course of a few hours the attack passed off, and the pulse returned to its normal rate, between 60 and 70, with complete disappearance of the nervous symptoms. A slight attack occurred in St. Paul's Cathedral, London, in October, 1900, and again in November, 1901, in his own house. A more serious and more prolonged seizure was experienced at Christmas, 1901, after which the normal was again reached. This condition of matters continued until July, 1902, when there was a sudden attack at church, with a pulse-rate of 16, and syncope symptoms. In February, 1903, another seizure occurred in a tramway car, and the same afternoon another attack came on in the street. The condition of the pulse during these attacks was not observed, as he was not seen by his medical attendant until afterwards. During the same month he

went to London in order to attend the meeting of the General Council, and had one or two attacks of syncope character, but the pulse was not observed to be below 40 at this time. Towards the end of the month he returned to Edinburgh, and was found to be very faint; his pulse then was 40. In March there were several attacks, and the pulse fell to 32 per minute. During the rest of his life the pulse was never found to be above 34, or below 28; it was almost invariably 32 per minute. From March, 1903, until June, 1907, when he died, there was no syncope or epileptiform attack. The patient manifested the keenest interest in his own condition, and encouraged every inquiry into the nature of his affection. He was seen by many distinguished men from time to time, all of whom expressed their views in regard to the nature of the disease. From first to last there was a good deal of gastro-enteric catarrh, with dilatation of the viscera and considerable constipation. There never was any renal affection, and the respiratory organs were wonderfully healthy, with the exception of slight impairment of the percussion sounds at the apices, accompanied by harsh breathing. After the cessation of the attacks of fainting and palpitation there never were any nervous symptoms. The patient slept well, and every intellectual faculty was alert to the end of life. The circulatory organs presented features of the greatest interest. There was a distinct cervical venous pulse of the auricular type; the apex beat was slightly further to the left than usual; the impulse was well sustained and perfectly regular, with a usual rate of 32; the arteries were somewhat thickened, but not in any way resistant; the condition of arterial pressure will be mentioned later. Percussion of the heart showed some enlargement, there being some dilatation with hypertrophy. On auscultation the first sound was replaced by a loud, high-pitched murmur, heard over the whole præcordia, and particularly distinct at the apex; the second sound was loud and ringing, especially about the aortic cartilage. Between the incidence of the systolic murmur and its attendant second sound there could always be heard perfectly distinct sounds, usually two in number, which were by no means loud; these were assumed to be caused by the pulsation of the auricles. Careful comparison of tracings taken from the jugular veins, the brachial and radial arteries, and the cardiac apex, amply confirmed this impression, as there were always two, if not three, elevations made by the movements of the cervical veins for each ventricular impulse. It was perfectly clear that the cause was one of partial, or incomplete, heart-block, as there was no absolute dissociation of ventricular and auricular movements, the ventricular pulsation being immediately preceded by an auricular impulse, although the interval between auricular and ventricular pulsation was not always exactly the same. In other words, the conductivity varied considerably. At a later period the condition seemed to pass into complete block. It was very interesting to find that the arterial pressure was extremely high during the systolic period, reaching as much as 230, and falling to 75 during the diastolic period. A comparison of all the phenomena with similar cases which have been under our care has shown us that it was a very interesting example of the Adams-Stokes syndrome due to heart-block. The termination came with dramatic suddenness after the patient had passed through a period free from any disturbing symptoms. At the *post-mortem* examination, which was expressly ordered by himself, the heart was found to be enlarged, measuring $17 \times 12 \times 11$ cm. The circumference of the heart 2 cm. below the auriculo-ventricular groove was 37.5 cm.; the subpericardial fat was abundant; the cavities were all dilated and hypertrophied; the hypertrophy of the tænia terminalis was well marked. In the right ventricle there were patchy thickenings of the endocardium; the tricuspid valve showed some fibrous thickening, but no calcification; the pulmonary artery and valve were healthy; the segments of the mitral valve were thickened and calcareous, the basal part of the aortic cusp being particularly affected; the chordae tendineae were somewhat thickened, but not shrunken, and the fibrous change extended into the apices of the papillary muscles; the endocardium showed patchy thickening, greyish-white fibrous areas being seen on some of the columnae carneae; the cusps at the aortic orifice were all thickened, but not shrunken or

adherent to one another, and their basal parts were calcareous; the sinuses of Valsalva were dilated; the aorta was atheromatous, as were also the coronary arteries whose branches in the heart wall were seen as greyish-white lines. A portion of the septum of the heart containing the auriculo-ventricular node and the auriculo-ventricular bundle was examined microscopically, and a similar comparative study was also made of the same region in healthy hearts, examined in serial sections. The examination showed that there was a dense fibrous transformation spreading from the aortic cusp of the mitral valve into and largely replacing the normal tissue of the auriculo-ventricular node and first part of the bundle. The fibrous tissue was dense, and presented irregular areas of calcification, so that the appearances differed very strikingly from those presented by the interlacing network of fibres in the node and all the corresponding parts of the healthy heart. The auriculo-ventricular bundle further down, nearer the membranous septum, and towards its bifurcation, showed less fibrosis and no calcification, although calcareous deposits were found in the adjacent fibrous tissue. The tissues at the junction of the superior vena cava and right auricle were also examined microscopically; the most important change in this region was found to be a pronounced fatty infiltration.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a meeting on February 3rd, Dr. P. BOOBYER, President, in the chair, Dr. R. D. MAXWELL, Obstetric Registrar to the London Hospital, delivered an address on the *Operability of cancer of the cervix in the light of recent operative technique*. Pointing out how frequently an operation showed the disease to be far more extensive than had been anticipated, he urged the need for examination of doubtful cases under anaesthesia, with exploration and microscopic examination of the cervical mucosa. Comparing the results of operation by the vaginal route with abdominal panhysterectomy (implying complete segregation of the cancer) as advocated by Wertheim, cure was much more likely in the case of the more radical abdominal operation, and the pioneers in this particular field deserved credit for not being deterred by a high immediate death-rate at first associated with it. At the same time he thought such an operation ought not to be performed after the age of 60. Briefly alluding to the vesical and other urinary complications associated with convalescence from Wertheim's operation, Dr. Maxwell pressed the importance of systematic education of the female population in the early symptoms of cancer, so that cases might come under expert notice much earlier than was the rule at present. As the result of the crusade against cancer in Germany initiated by Winter, of Königsberg, the percentage of operable cases had there materially increased; and similar good might result in the United Kingdom from the pamphlets on cancer placed in the hands of registered midwives during the last two years.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—At a meeting on January 22nd, Dr. W. H. CHRETHAM in the chair, Dr. MAXWELL TELLING, in a paper on the clinical relationship of *Erythema nodosum*, adduced evidence to show that this disease was not one of the manifestations of the rheumatic infection. He also contended that it was not a variant of the erythema exudativum multiforme of Hebra, but that it was a specific disease allied to the acute eruptive fevers. Dr. MYER COPLANS showed organisms of *Vincent's angina* obtained in each of four outbreaks within the past three months in Leeds and the East Riding. The organisms were spirilla and fusiform bacilli obtained from cultures of throat swabs on alkaline-glucose-serum slants (1 per cent. glucose). Mr. B. G. A. MOYNIHAN showed an appendix removed within three hours of the onset of an acute attack of severe pain associated with an extremely rigid abdominal wall. The symptoms suggested a *Perforation of the appendix*, but the condition found was one of thrombosis of the vessels in the distal part. The distal part of the appendix, the territory of the thrombosed vessels, was a deep purple colour, the remainder being pale. This condition, it was suggested, was the early stage of which gangrene and perforation are the later stages. Dr. E. F. TREVELYAN showed (1) a boy aged 14 with *Disseminated sclerosis*, which the parents attributed to an injury sustained seven months ago. Gait slightly

reeling; speech drawing; aimless laughing; nystagmus; convergence deficient; intentional tremor; knee-jerks exaggerated with left foot clonus. There had been several epileptiform seizures. (2) A girl aged 24 with *Epilepsy*. In at least two fits there had been a precurse motor aura, the patient being impelled to run forward before unconsciousness supervened. Mr. J. F. DONSON showed a *Heart with stab wound* from a butcher's knife penetrating the left ventricle. The wound was sutured with two catgut stitches with great immediate improvement; however, death resulted from sepsis sixty hours after operation. Mr. J. STEWART showed a specimen of *Tubal gestation* removed from a patient, aged 24, who was suckling her second child, aged 5 months. Mr. MICHAEL TEALE showed a child with an opacity of the greater part of the capsule of the lens of each eye, probably due to a persistent remnant of the embryonic capsule of the lens.

LIVERPOOL MEDICAL INSTITUTION.—At a meeting held on January 28th, Mr. T. H. BICKERTON, President, in the chair, Mr. THIELWALL THOMAS read notes on two cases of *Actinomycosis* of the cervico-facial type. The first occurred in a housemaid who had nothing to do with cattle; the disease was very severe, and involved the facial bones. The second was that of a young man who looked after a horse and frequently chewed corn. Both cases commenced as gum-boils. The treatment consisted in free incisions, packing the wounds with gauze soaked in tincture of iodine, and the internal administration of potassium iodide and iodinipin. Both cases recovered after an illness lasting many weeks. Mr. MONSARRAT referred to a case under his care in which the infection was pharyngeal in origin, and closely resembled tubercle. In spite of energetic treatment, including a vaccine, the patient died from extension to the vertebrae. Mr. DOUGLAS-CRAWFORD mentioned two cases which he had reported two years ago—one of the cervico-facial type, and the other which had attacked the abdominal wall; both cases were treated by excision, local application of iodinipin, and potassium iodide internally. Both ultimately recovered. Dr. BAKER YOUNG described a case of *Muscarin poisoning*. The symptoms were those of catarrhal jaundice, followed by peripheral neuritis and paroxysmal dyspnoea. Atropin was the drug chiefly employed, but the case ended fatally. Mr. LITTLER-JONES reported two cases of *Diaphragmatic hernia*. One followed a perforating wound of the left wall of the chest; a portion of the eighth rib was excised, the diaphragm repaired, and the patient ultimately made an excellent recovery. The second case was that of a child who presented symptoms of intestinal obstruction. The hernia was reduced through an abdominal incision, but the patient died some days later from severe haematemesis. Drs. RUNDLE and STENHOUSE WILLIAMS read a note on the *Serum treatment of diphtheria*, with special reference to anaphylaxis.

MEDICAL SOCIETY OF LONDON.—At a clinical meeting on February 8th, with Mr. CHARTERS J. SYMONDS, F.R.C.S., in the chair, the following cases were shown:—Dr. A. F. VOZLCKER: A case of widespread *Peripheral neuritis* of uncertain origin exhibited to the Society on November 9th, 1908, as a doubtful case of diffuse glioma of the cord; also a case of *Hydatid cyst of the liver successfully treated by drainage*. Dr. G. A. SUTTERLAND: A case of *Generalized paralysis* of uncertain origin in a boy 3 years of age, admitted to hospital on October 2nd, 1908, after an indefinite illness of six days' duration, characterized by loss of appetite, abdominal pain, and constipation, when he lay in a curiously apathetic condition and made no attempt to move arms or legs. There was a frequent, loose, and toneless cough. All the extremities were flaccid and paralysed, very slight power being present in the upper extremities only. The knee-jerks were absent and a doubtful flexor response was elicited on the left side. The abdominal and cremasteric reflexes were absent. There was rectal and vesical incontinence. The diaphragm was apparently quite paralysed. After twelve weeks he was now definitely improving, and was putting on weight and gaining power in all the paralysed muscles. Mr. P. MAYNARD HEATH: A case of *Typhoid peritonitis of the femur*. Dr. F. PARKES WEBER: A case of *Acquired chronic acholuric jaundice*

with *splenomegaly*; a case of *Splenomegaly*, due to inherited syphilis (?); and a case of *Raynaud's gangrene* in a malarial subject. Dr. WILFRED HARRIS: A case of *Syringobulbia*. Fifteen years ago the patient had haematemesis. He had since been subject to pains in the right side and shoulders and the back of the head. There was marked hemiatrophy of the right half of the tongue and coarse nystagmus on looking to the right. In regard to sensation there was complete loss to pin-prick, heat and cold over the second, third, and fourth cervical root areas on both sides. Mr. CHARTERS J. SYMONDS: A case of *Congenital dislocation of the hip four years after Lorenz's operation*; and a case of *Stricture of the oesophagus*, showing the method of treatment by a long rubber tube. Dr. W. H. CROLY (introduced by Mr. L. Eliot Cressy): A case of *Epidermolysis bullosa*. Mr. T. H. KELLOCK: A case of *Deformity of long bones in a boy* aged 6 years. There was considerable laxity of the joints, chiefly noticeable at the right hip, which it was possible to rotate outwards to a very abnormal degree. Skiagrams showed bending of the shafts of the long bones and great irregularity of ossification at the epiphysal ends. The pelvis was a good deal deformed, approaching the tri-radiate form. Dr. F. S. PALMER: A case of *Spinal caries followed by pressure paraplegia*, in which considerable recovery followed laminectomy.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.—At a meeting held on February 2nd, Dr. MAY THORNE in the chair, Miss GARRETT ANDERSON gave the history of a case of *Carcinoma of the colon*. The patient was a woman aged 59, in whom the growth had been felt per vaginam as a small movable mass just above the brim of the pelvis. Eight inches of the sigmoid were excised through an oblique incision in the right inguinal region. As the patient's condition was too serious to allow an anastomosis to be made, the distal end of the bowel was closed, and the proximal end was brought out in the colotomy wound. A Paul's tube was used for the first few days. She made a good recovery, and was shown wearing a Pengelly-Bailey belt, which was recommended as being clean and easy to manage. The parts removed at the operation showed an annular growth of columnar cell carcinoma. Miss GARRETT ANDERSON also showed, on behalf of Miss Cock, a woman, aged 45, who for three years had noticed a small *Lump in the left breast*. It was hard and was fixed to the skin, and there were some small hard glands in the axilla. The swelling was considered to be a scirrhus, though the history was somewhat long. The question was raised whether there was a secondary growth in the sacrum as the patient complained of severe pain in that region. Miss DONNE showed a girl with an *Osteoma growing from the upper border of the scapula*. The scapula was also elevated, owing to absence of the lower part of the trapezius, and there was scoliosis with a triple curve. Mrs. SAVILL showed a case of *Scleroderma*. Four years ago the patient had been treated daily, over a period of two years, with x rays, and her left arm presented the typical appearance of x-ray dermatitis, with scarring (keloid in places), tetangetectases, and two painful ulcers. The PRESIDENT showed (for Mrs. Scharlieb): (1) A *Cystic tumour of the uterus* with the microscopic characters of an endothelioma. The patient had been aware of the existence of a tumour for eleven years. (2) A *Malignant adenoma infiltrating the wall of the uterus* as far as the peritoneal coat. There was a history of irregular and profuse menstruation for three years, and, for a shorter period, of loss of flesh, anaemia, and a foul vaginal discharge. The patient died of heart failure thirty hours after panhysterectomy, death being preceded by vomiting of tarry material, possibly due to secondary growths in the stomach. (3) An *Epithelioma of the vagina*. The patient from whom the specimen was removed had worn a ring pessary for twelve years, and seven months before the growth was discovered the pessary had to be forcibly extracted, as the vaginal tissues had grown over it.

The State Children's Association has issued a leaflet explaining the provisions of the Children Act, 1908. The leaflet (price 1d.) and fuller information regarding the Acts affecting children can be obtained on application to the Secretaries, 58, Old Broad Street, E.C.

Reviews.

VACCINES AND IMMUNITY.

SINCE Professor Paul Ehrlich first enunciated his theory—familiar now as the side-chain theory—by means of which he endeavoured to provide an explanation of the processes by which immunity is regulated, various efforts have been made to make the details of the theory intelligible to those interested in the endeavour to bring it into closer touch with the various pathological problems connected with the study of medicine. Continental workers, with a whole-hearted acceptance of the theory as a working hypothesis, have made rapid strides in the direction of further investigation along lines indicated by Ehrlich, with the result that most important facts have been slowly but surely accumulating. These investigations are scattered broadcast in numerous periodicals, and writers like Aschoff, Römer, Kolle and Wassermann, and more recently Kraus and Levaditi, have endeavoured to bring these investigations together in monographs and textbooks, so presenting the advances made as a result of Ehrlich's fundamental theoretical deductions. For reasons which are not far to seek, these results have hardly found a just recognition in English textbooks of medicine and pathology. First amongst these reasons is not the cumbersome terminology used, nor the speculative arguments advanced, but very largely hesitation on our part, due probably to our innate dislike for involved theoretical discussion. A short monograph, written by Dr. SCHATILOFF,¹ is published just at a time, however, when the medical world has realized that it can no longer remain satisfied with the old pathological shibboleths which were based on the findings of morbid anatomy. We are no longer satisfied with the expressions "cloudy swelling," "colloidal degeneration," and "amyloid transformation," for these terms merely describe the shipwreck produced by processes which we do not understand. No doubt Sir Almoth Wright's work on opsonins has opened our insular eyes more widely to the principles of immunity than all the advances made by Ehrlich and his school, if for no other reason than that the theory of opsonic reaction to infection is a much more simple and demonstrable one. No doubt it is, at present at least, practically impossible to find a place for opsonins in Ehrlich's scheme of immunity, but this is no excuse for neglecting to appreciate the more recent advances based on his theory. Dr. Schatilloff devotes the first thirty pages of his publication to a most successful attempt to render Ehrlich's theory more intelligible, and we must confess to great assistance derived from the discussions in this part of the book, and from the most serviceable diagrams which pictorially represent what is too often difficult of comprehension. The meaning of such terms as "toxones," "toxoids," "lysins," "complementoids," and "precipitinogens," is no longer obscured by terminological difficulties. Even if Dr. Schatilloff had written no more than these first thirty pages, he would deserve great credit, for his efforts, if we are not greatly mistaken, will help the reader to a thorough grasp of the difficulties which attend this new theory. No doubt there is still very much to be done in filling the obvious gaps in our knowledge, even when helped by the most recent advances based on Ehrlich's hypothesis, but the writer has wisely shunned what is still in dispute, and gives to the reader a survey only of what is generally accepted. We should signally fail in our duty, however, if we did not call the reader's attention to the admirable work contained in the last fifteen or sixteen pages, for within these narrow limits Dr. Schatilloff has contrived to give the reader full details of a reaction of the serum of infected patients which, already acting as a touchstone, is showing the existence of infective agents which so far have baffled all detection—for example, the acute infections which cause measles, whooping-cough, scarlet fever, and the like. For once we meet with a German book which disregards all references, and is satisfied to give the facts only; this is disappointing in some ways, but the gain in terseness is very great. The amount of work which has followed upon the important results published by Bordet and Gengon could not be given fully in the small compass of this part of the book, but the

process itself, as originally planned by Bordet and Gengon, and the corrections and improvements suggested by subsequent workers, are all fully set out, notably those initiated by Wassermann in his application of the test to the investigation of syphilis.

Various well-known authorities of the Pasteur Institute in Paris have collaborated in the publication of a volume on bacterial therapy, vaccination, and serumtherapy,² forming part of the *Bibliothèque de Thérapeutique*, edited by MM. GILBERT and CARNOT. Metchnikoff gives a fairly full and reasoned account of intestinal therapy by the ingestion of acid-forming bacteria, and considers the varieties of bacteria which may be most suitably employed for this purpose. He seems a little angry with the people who argue that this treatment may be dangerous on the ground that in rabbits the experimental administration of lactic acid produces degenerative changes in the vascular system, and remarks sarcastically:

Applying to mankind the results of experiments on rabbits it would be necessary to conclude that man is extraordinarily susceptible to chicken cholera, that he is absolutely refractory to recurrent fever, and that he cannot contract syphilis except when the virus is inoculated in the eye.

True, the constitution of a rabbit is different from that of a man; but it does not follow that these experiments on rabbits are worthless; whilst not amounting to a refutation of Metchnikoff's favourite doctrine, they at least raise a point demanding further consideration. Sacquépée's lengthy article on vaccination against small-pox is good on the whole, but we are surprised that he does not attach more importance to the purification of vaccine lymph by the use of chloroform; in looking over his article the only reference which we have found to this method is a single line on p. 67. The articles on vaccination against hydrophobia by Remlinger, and on diphtheria antitoxin by Louis Martin, are both valuable, but do not call for any special comment. We note that Vaillard and Dopfer, writing on the serumtherapy of bacillary dysentery, do not think much has been gained by the efforts made to produce a polyvalent serum.

The necessity for a polyvalent serum does not seem to have been demonstrated hitherto, at least so far as our own practical experience goes. Although for the immunization of our horses we have employed solely cultures of the Shiga-Kruse type, all our dysentery cases, whether produced by the Shiga-Kruse or by the Flexner bacillus, have been influenced in an equally favourable manner.

The article on the serumtherapy of epidemic meningitis is by Wassermann and Leber of Berlin. These authorities regard the specific serum as an important therapeutic agent when inoculated intraspinally, and quote a recent epidemic in which the mortality amongst the untreated cases was from 78 to 80 per cent, whilst amongst the cases which received large doses of the serum the mortality did not rise above 12 to 15 per cent. Dujardin-Beaumez, to whom is entrusted the article on serumtherapy and vaccination in bubonic plague, makes the significant remark that "the true prophylaxis which is effective against plague is the extermination of rats, the sole propagators of this disease." We are disappointed to find that the chapter on serumtherapeutics in poisoning by snake venom, written by Calmette, is cut down to the meagre space of nine pages. Calmette is one of the greatest living authorities on this subject, which is one deserving of lengthy treatment, and we think that the value of the volume as a whole would have been increased if the article had been expanded. The editors of the book are to be congratulated on having secured the services of so many eminent writers, and we look forward with interest to the appearance of further volumes in the same series.

DRS. KRAUS and LEVADITI, who are editing a treatise on the technique and method of immunity investigation,³

(Sup. roy. 8vo, pp. 359-1138, 2 coloured plates, 1 chart, and 94 illustrations in the text. M. 20.) Zweiter Band. Erste Lieferung. (Pp. 278, with illustrations. M. 8.)

³ *Die Ehrlichsche Seitenkettentheorie, erläutert und bildlich dargestellt* [Ehrlich's side-chain theory explained and diagrammatically represented]. By Dr. P. Schatilloff. Jena: Gustav Fischer. 1908. (Roy. 8vo, pp. 48, Tab. 7. M. 2.)

have issued the second part of the first volume. The article on vaccination against variola, by Dr. Gustav Paul of Vienna, covers the ground fairly well, but is written very conspicuously from the German point of view, and may appear to English readers to treat work done in this country less fully than it deserves. Dr. Paul does not think that lymph purified by the chloroform method can be regarded as reliable for general use; and there is no necessity, he argues, to resort either to this or to any other method for the rapid elimination of extraneous organisms, provided that proper precautions are taken to produce the lymph in a comparatively pure condition. For this purpose he recommends the use of a protective covering (*Tegminderband*) which is applied over the area where the calf has been inoculated; this procedure has been followed in Vienna since 1897. Perhaps Dr. Paul would attach more importance to the chloroform method if he studied it more thoroughly. In the article on protective inoculation against typhoid fever by Dr. Friedberger, the most noteworthy feature is the full account given of Wright's work and the statistics on this subject. In the next chapter, on preventive inoculation against cholera, Dr. Friedberger betrays a little too much anxiety to pick holes in Haffkine's brilliant work; he informs us that "the essential nature of cholera-immunity" was first brought to light by certain German investigators. Similarly the chapter on plague prophylactics, by Drs. Wassermann and Leuchs, would have been improved by a fuller recognition of the work done under the auspices of the British Government. There are several chapters on tuberculosis. Dr. Löwenstein contributes two on human tuberculosis, dealing with the therapeutic and diagnostic uses of tuberculin; Dr. Römer writes on tuberculin testing and vaccination in bovines; and Dr. von Pirquet discusses the cutaneous and conjunctival reactions with tuberculin. These articles all contain useful collections of data, but do not attain to a very high standard of impartial criticism. Dr. Römer's articles, for example, reveal a strong personal bias in favour of the Behring school. The great merit of the book lies in the very full and carefully written descriptions of technical methods, and in this respect its utility will be highly appreciated by all workers on immunity. In discussing theories some of the writers are less successful. They rely too much on the bald "historical" method of presenting a long string of persons' names with a particular theory or opinion attached to each; and when they attempt to criticize, the evidence of impartial judgement is often obscured by special pleading in favour of a particular point of view. The first section of vol. ii will prove of great service to those engaged in the practical work of antitoxin preparation. Professor Kretz, of Prague, describes the technique of producing and collecting diphtheria antitoxin from horses, and Dr. Levaditi gives a very interesting account of the preparation of antibacterial and antitoxic immune sera from large animals in the serum department of the Pasteur Institute in Paris. The testing and standardization of diphtheria antitoxin is dealt with by Dr. Madsen, of Copenhagen; the chapter on tetanus antitoxin is by Drs. Eisler and Pribram, and includes a short discussion of the employment of this antitoxin for prophylactic and therapeutic purposes; and the preparation and employment of antitoxic serum in cases of dysentery caused by the Shiga-Kruse type of bacillus is fully described by Dr. Doerr, of Vienna. Another important article in the volume is Professor Calmette's account of the preparation of antitoxins against snake poisons.

In the second edition of his *Vaccine Therapy and the Opsonic Method of Treatment*⁴ Dr. ALLEN has incorporated a large amount of new material and has increased the bulk of the volume by nearly a hundred pages. A special feature of the new edition is the expansion of the chapter on infection by the tubercle bacillus. The author attaches high importance to the differentiation of tubercle bacilli found in the human body into "human" and "bovine" types, and for general clinical purposes recommends the use of a vaccine prepared from a mixture of these two types of bacilli. Unfortunately an element of confusion

arises owing to the fact that certain clinical pathologists make use of these terms "human" and "bovine" in ways which would not be acceptable to Koch and other high authorities who have established this differentiation on a definite basis of bacteriological experiment. Put briefly, what the bacteriologist means by a "bovine" strain is one which grows poorly on artificial culture media, and is of high virulence for rabbits, in contrast to which the characters of "human" strains are abundant growth on artificial media, and relatively low virulence for rabbits. When tested by these criteria, very nearly all the tubercle bacilli which have been obtained from human tuberculous lungs have been found to be of the "human" type. Dr. Allen, however, appears to attach importance to certain clinical pathologists who, relying on tests other than those mentioned above, have arrived at very different conclusions. For example, he quotes one observer who from "a most careful study" of 112 cases of pulmonary phthisis formed the opinion that 68, or 60.8 per cent., of these cases "showed a symbiotic working of the human and bovine types," and that 6 cases, or 5.3 per cent., "had almost exclusively bovine bacilli." We must remind Dr. Allen that the majority of bacteriologists are not prepared to concede that the *typus bovinus*, as defined by Koch and subsequent workers, occurs in the human lungs with anything like the frequency which a few physicians and opsonists imagine.

INJURY AS A CAUSE OF NERVOUS DISEASE.

ACCURATE knowledge of the place and importance of bodily injury in the causation of diseases of the nervous system is of great importance to every medical man who may be called upon to give evidence on this point in courts of law. The conclusions of a critical survey of over 1,500 cases of this kind on which judgement was given in legal courts, all of which cases had come under the personal observation either of Dr. Kurt Mendel or of his father, Professor E. Mendel, of Berlin, should, therefore, prove of use, particularly in these days of frequent application for compensation under the Workmen's Compensation Act. Dr. KURT MENDEL's volume⁵ on injury in the etiology of nervous diseases, large as it is, is yet restricted to the discussion of the effect of trauma in general paralysis, cerebral tumour and abscess, apoplexy and meningitis, tabes dorsalis, multiple sclerosis, syringomyelia, myelitis, amyotrophic lateral sclerosis, and progressive muscular atrophy; progressive muscular dystrophies and neuritis; paralysis agitans, exophthalmic goitre, acromegaly, and epilepsy, and does not enter into the great field of traumatic neurasthenia and hysteria which, on account of their importance, will be treated in a separate volume to be published later. Each of the diseases above mentioned is treated in a separate chapter, illustrated by clinical notes and the judicial verdicts obtained. Few subjects are more hedged by difficulties. Apart altogether from the difficulty of duly apportioning the relative importance of the influence of trauma on the one hand, and predisposition, congenital or acquired disposition, on the other, there are difficulties as to matters of evidence, such as the proof that the individual concerned was sound in health up to the day of the accident; that other etiological factors besides trauma were absent; the time relation of the injury to the appearance of the disease, and the amount of injury received. To a certain extent these questions are of scientific and not forensic importance, for in German courts it is not necessary to prove that the injury was the sole factor; also the deepening of an already existing disease by accident has the same value as its traumatic production *de novo*; and further, in practice the court is content with a considerable degree of probability and when in doubt is in favour of a traumatic origin. For the author's discussion we must refer inquirers to the book itself, which is well worth reading, and need only give here his main conclusions. After the general statements that any injury, and in particular that of the skull or spine, may increase an existing nervous disease, or prejudice its course, or stir up a latent disorder, and that an injury may bring about a *locus minoris resistentie* on which soil other causes may become operative—for example, head injury in syphilitics may

⁴ *Vaccine Therapy and the Opsonic Method of Treatment*. By R. W. Allen, M.D., B.S. Second edition. London: H. K. Lewis, 1908. (Demy 8vo, pp. 256. 7s. 6d.)

⁵ *Der Unfall in der Ätiologie der Nervenkrankheiten*. By Dr. Kurt Mendel. Berlin: S. Karger, 1908. (Sup. roy. 8vo, pp. 189. M. 8.)

determine general paralysis, or in tuberculous subjects, tuberculous meningitis, etc.—Dr. Mendel considers (1) that the following diseases: General paralysis, brain tumour, tabes dorsalis, multiple sclerosis, amyotrophic lateral sclerosis, progressive muscular atrophy, progressive muscular dystrophy, paralysis agitans, Basedow's disease and acromegaly, being of endogenous nature are never of purely traumatic origin, however severe the injury; (2) that polyneuritis and brain abscess may be the direct result of injury, in the latter case, of course, in association with septic infection; and (3) that apoplexy, meningitis, myelitis and epilepsy may be brought about in completely sound individuals with no disposition to any of these diseases, as the result of injury, and may thus occur as purely traumatic diseases.

The considerable damage—amounting even to large losses of substance in certain parts, for example, in the frontal and parietal convolutions, etc.—which the brain can sustain without consequent mental or indeed any symptoms, often occasions surprise, and has led to the description of these parts as “dumb” areas, *stumme Gehirnteile*. Not long ago Professor BURR published an able paper¹ in which he maintained that head injury, no matter how severe, never produces insanity except in predisposed individuals. Possibly Professor Burr's view is an extreme one, but in any case the absence of symptoms, say in cases of cerebral tumour, and the restoration and mode of restoration of functions after extirpation of the cortical areas subserving these functions, as demonstrated by Hitzig, offer a wide and fruitful field for inquiry. For this reason, a pamphlet on the restoration of function in diseases of the brain,² reprinted from the *Monatsschrift für Psychiatrie und Neurologie*, Bd. xix, Heft 1, by Professor ANTON, the successor of Wernicke at Halle, will be read with interest. Professor Anton shows that there dwells in the human central nervous system a wide capacity for adaptation, an innate power of self-regulation, not only towards stimuli and effects from without, but with regard to internal disturbances of the cerebrum. The explanation of this power of adaptation or ability to take on vicarious function is given in a sentence, when Professor Anton says that “the constituent elements of the central nervous system possess greater possibilities of function than normally come into action; as is proved whenever another part is abolished.” Further, the nearer the injury is to the periphery the more restricted the possibility of vicarious action, or the higher the injury the greater the possibility, and consequently vicarious function in a case of cortical injury can be most easily assumed by neighbouring parts, the symmetrical parts in the other hemisphere and the subcortical centres. This compensatory action, however, if sufficiently pronounced, takes effect at the expense of other functions; other brain areas become more excitable, possibly also more easily fatigued; the sound areas undergo to some extent an alteration of function, and there is, in fine, a readjustment of the equilibrium of the whole, corresponding to the production of a new cerebral type. We have thought it sufficient to give here only the guiding principles expounded by Professor Anton in his too brief paper; for the author's valuable references to experimental cases, for the expression of this principle of vicarious function in symptomatology and for the practical lessons to be drawn therefrom we must refer readers to the work itself.

THE BRAIN IN RELATION TO THE SKULL.

THE atlas³ prepared by Professor HERMANN, of Erlangen, consists of seven sections illustrating the topographical anatomy of the brain and skull, and should prove of great value to anatomists, surgeons, and neurologists.

Professor Hermann has devised a careful and ingenious means of accurately determining by section and topography the relation of the skull to its contents, and gives 69 artistically-executed coloured photographic plates,

representing the skull with its sutures, the dura mater with its vessels, the convolutions and fissures, and a successive series of sections through the brain from above downwards, lateralwards, from before backwards, and from behind forwards. A study of these plates enables one to obtain a correct knowledge of what structures an instrument would pass through, if it travelled straight or obliquely through any part of the skull. Moreover, some idea of what structures a bullet would damage could be arrived at after locating its position in the skull by a skiagram.

The plates have either a transparency in front, naming all the structures seen through in a clear and comprehensive manner, or a diagrammatic tracing opposite with explanations of the relations of the calvarium and its sutures to all the subjacent parts or the relation of the various structures of the brain to the base of the skull. Plates 63, 64, 65, and 66 show projections of the lateral ventricles from above, from in front, from behind, and from the side; the situation of the principal branches of the middle meningeal artery is shown. As the author remarks, these plates should be useful as a guide in the operation of puncture of the lateral ventricles. Section 7 contains some exceptionally fine plates, which should be very useful to the surgeon.

The line system of Krönlein is adopted for cranio-cerebral topography, and in plate 67 the skull is seen exposed, and the lines are exhibited on the surface, together with the situation of the fissure of Rolando and the Sylvian fissure, with its branches as determined by this method. The next plate, 68, by ingenious arrangement and photography, demonstrates the exact relation those lines which were seen on the external surface bear to the convolutions and fissures of the brain after removal of one-half of the cranium and the membranes. The last plate, 69, shows the relation of Krönlein's system to the structures exposed when one-half of the brain is removed by mesial section through the corpus callosum, stem of the brain, and the cerebellum. No medical library of importance should be without a copy of this valuable pictorial anatomy of the brain in relation to the skull.

SURGERY.

Modern Surgery, by Dr. ROSWELL PARK,⁴ is an attempt to epitomize the modern principles and practice of surgery for the use of those who require such a condensed presentation. The author covers a very wide field within a comparatively small compass, and has studied the art of compression to some purpose. Some day textbooks of surgery will still further unload matter which they are not really called upon to supply, and get rid of chapters on inflammation, infection, and general parasitology which belong to treatises on general pathology. Parts I and II of the first volume treat of surgical pathology and surgical diseases; Part III of surgical principles, methods, and minor procedures. This last part is rather shapeless, and facts are not so arranged that the reader gathers clear ideas as to what methods the author recommends. Nor can some of the methods detailed be called modern—for example, the intraspinal injection of cocaine. No surgeon who has any experience of intraspinal anaesthetization, or is acquainted with the literature of the subject, would use this drug to-day. Injury and repair occupy Part IV; wound treatment is included, and this section is clearly written and adequately illustrated. The remainder of the first volume is devoted to surgical affections of the tissues and tissue systems. The author's views on the parasitic origins of tumours are temperately stated; a series of illustrations of “parasites” in cancer are given with the statement that their “existence is undeniable.” This part of the volume is marred by vagueness in definitions, and there are several instances of statements, more especially those bearing on pathology, which cannot fail to confuse the student. To describe the “tuberculous” as one of the varieties of acute osteomyelitis; to insist on a distinction between osteosarcoma and sarcoma of bone; to classify arthritis into dry, acute, purulent, and chronic, is to make statements not sufficiently precise for a textbook. The second volume treats of

³ Gehirn und Schädel, eine topographisch-anatomische Studie in photographischen Darstellungen. Von Dr. R. Hermann, a.o. Professor der Anatomie an der Universität Erlangen. Jena: Gustav Fischer. 1908. (Sup. roy. 4to, pp. 12; 69 zum Teil Mohrfarbenen Lichtdrucktafeln. M. 60.)

regional surgery. One meets early with a plate (xlv) which presents the topographical anatomy of the cerebral cortex according to the ideas of five years ago, corrected by the researches of Sherrington and others. In its clinical descriptions, its illustrations, and its synopses of treatment, however, this volume is a reliable guide. The author is conservative, but at the same time in sympathy with advances in surgical practice, and his volume may be consulted by student and practitioner with advantage.

The seventh edition of this *Manual of Surgery*,¹⁰ so widely known by students under the familiar title of "Rose and Carless," needs no criticism. In this, as in previous reissues, careful revision with judicious alteration here and there have maintained the high position of the book as an authoritative treatise on modern surgery. The authors can fairly claim, among many other merits, that of having kept their manual, which has passed through seven editions in the course of ten years, within convenient bounds. In his interesting preface, Mr. CARLESS, after an allusion to his colleague and to the share he has taken in the preparation of this edition, points out that the task of keeping the book at its present high level will be increased rather than lightened in future years. Surgery, he states, is in an eminently plastic condition: new problems are awaiting settlement, new therapeutical methods are being adopted, and novelties of all sorts are being exploited. It seems to be probable that the operating surgeon, while extending the range of his work in some fresh directions, will be ousted in others. Though we are not optimistic as to any immediate results of cancer research, it is gratifying to know that the surgical authorities who are responsible for this work are convinced that in some future edition they will be able to chronicle a more effectual and scientific cure of this disease than the present-day procedure, which they regard as mutilatory. In our renewed praise of this manual full recognition is due to those who have so ably assisted the authors in the work of revision and in additions to the pathological and electrical subjects. We would venture to suggest that it would be well in future to include a list of the illustrations, to which in the present edition some clear and good additions have been made by Dr. Dupuy.

The excellent *Treatise of Operative Surgery*, by Dr. BICKHAM of New Orleans, has, in its third edition,¹¹ been so much enlarged and rendered so very comprehensive that it is likely, while attracting increased favour from the teacher and the operating surgeon, to be regarded as an inconvenient, if not impossible, guide by the student. In its present form it is undoubtedly a standard and very reliable work of reference, and thoroughly fulfils the author's original intention of describing the best and most approved technique of modern practical surgery. In his heavy task of revising the work Dr. Bickham has, he very gratefully acknowledges, received constant aid and encouragement from his wife. He has also good reason for thanking the lady artist who in this, as in previous editions, has done so much by her original illustrations to make quite clear the teaching of the text.

Dr. BOCKENHEIMER's surgical atlas¹² is a selection of coloured pictures, 150 in number, illustrating types of disease which come to the surgeon for treatment. The pictures are extremely good, the equal of those in any clinical atlas. Faithfulness to the last detail is necessary in such illustrations if they are to be of any real service, and these fulfil this requirement. Naturally those of new growths occupy the first place in point of number, and they form a remarkable series. There are gaps, of course

—it would take many atlases to fill them—but the series is well chosen; the appearances are typical, and extreme examples have been wisely avoided. The accompanying text contains a description of each plate and paragraphs on differential diagnosis and treatment. In many cases also the clinical history of the patient is given, and this adds materially to the value of the plate. Students, surgeons, and teachers of surgery will welcome this atlas; the plates are so true that they merit detailed study, and are admirable for demonstration purposes.

Dr. W. STOECKEL, Director of the Gynaecological Clinic at Marburg, has compiled an atlas of cystoscopy,¹³ showing various morbid conditions of the bladder in disease of the female pelvic organs. The plates show both primary bladder lesions and lesions in this viscus secondary to affections originating outside it. Changes in the bladder in pregnancy in cystocele, and in cystitis are shown, and of particular interest in this group are the pictures of fistulae. The illustrations of conditions invading from the outside include carcinoma and parametritis. There are also pictures of ligatures, of a gauze tampon, and of a pair of artery forceps which made their way into the bladder. The plates are excellently reproduced, and form a series of much interest and value.

The new and revised issue of Mr. MANSELL MOULLIN's essay on *When to Operate in Inflammation of the Appendix*, will,¹⁴ we have no doubt, prove a useful and instructive guide to the proper treatment of the grave affection which is here discussed. In this collection of four clinical lectures will be found a full and definite statement of the necessity of prompt surgical intervention in all but a very few cases of acute appendicitis—a line of treatment, it may be pointed out, which, when advocated by the author in his earlier edition, was not so widely accepted in this country as it is at the present time. In the concluding lecture will be found an excellent review of the clinical phenomena of appendicitis, deductions being drawn from the more important of these with regard to the nature and prognosis of the inflammatory attack and the indications for immediate or for delayed operation.

NOTES ON BOOKS.

THE *Calendar* for 1908-9 of the University Correspondence College¹⁵ will be useful to intending candidates for the Matriculation Examination of the University of London since it contains the papers set at the January examination, together with answers and solutions. Some years ago the Senate resolved, we believe, to appoint moderators to look after the examiners; it would be interesting to know with what degree of diligence these officers exercise their moderating influence.

The Medical Inspection of School Children, a series of lectures delivered at the West London Post-Graduate College, is a reprint of six articles which have appeared in recent issues of *The Medical Officer*. The greater portion of the first two lectures will be found at first hand in the three Memoranda on School Medical Inspection issued by the Board of Education, but in the process of explaining the scope of the Board's suggestions matter of a useful character has been incorporated. The writer, however, has confused the Annual Report to the Local Education Authority with that to the Board of Education. Skin diseases, examination of the eyes, examination of the teeth, and ear, nose and throat affections are dealt with in the subsequent lectures. While there is to be found in each of these lectures much valuable information, there is an absence of appreciation of the facts that the school doctor is not employed at a hospital or dispensary, nor has he the time and opportunity of indulging in the luxury of extreme specialism. The possibility of carrying out many of the suggestions made does not seem to have been seriously considered. In publishing information for the help and guidance of the new school doctor care should always be taken that the material is suitable and, at least,

¹⁴ *When to Operate in Inflammation of the Appendix: Clinical lectures* by C. Mansell Moullin, M.D. Oxon., F.R.C.S., Senior Surgeon to the London Hospital. Third edition. London: John Bale, Sons, and Davidson, Ltd. 1908. (Demy 8vo, pp. 48, 2s. 6d.)

¹⁵ Cambridge: Burlington House; London: 32, Red Lion Square. Small 8vo, pp. 150, 1s. net.)

likely to be of use to him in the performance of his duties. This is not always the case, and in these lectures many matters are referred to concerning which, however interesting, it is problematical if the school doctor will, under present conditions, have the opportunity of utilizing the information given.

The tenth and last volume of *Green's Encyclopedia and Dictionary of Medicine and Surgery*¹⁶ has just been issued, and the editor may be congratulated on the completion of a task which was perhaps not altogether worthy of his distinguished abilities. Some years ago the same publisher issued an *Encyclopedia Medica* in thirteen volumes, and in the present publication a medical dictionary containing thousands of definitions has been incorporated with the encyclopedia, and a system of cross-references introduced. In addition, the opportunity has been taken to note important advances in medical and surgical practice, sometimes in the form of new articles, sometimes by addition to the older articles, sometimes by short paragraphs or definitions giving cross-references to the original contributions. The editor's expert knowledge of teratology has led to the inclusion of a large number of rarely-used terms connected therewith—a fault, if it be a fault, atoned for by a new and able article in vol. iii on human embryology. In vol. iv Dr. BALLANTYNE also contributes a long article on diagnosis in gynaecology, which, whatever may be said about its appropriateness in a dictionary, is certainly an excellent piece of work. A new article on heart-block, by Dr. J. S. Fowler, is a model of lucidity and conciseness, and the summary of recent views on immunity is satisfactory. We have reason to think that, from the point of view of the lexicographer, the later volumes are better done than the earlier, the editor no doubt gaining experience of this very difficult art during the progress of his task.

The character of the *Practical Hints in General Medicine*¹⁷ offered by Hospital Assistant K. S. AGNIHOTRI, Ph.G., of Panhala, in the Kolhapur State, can best be gathered from a few extracts:

80. Castor oil. In many parts of America castor oil in half-ounce or ounce doses is largely used as a fatening agent in place of cod liver oil. Life to concocture. The proper way to economize life is to sleep every moment that is not necessary or desirable that you should be awake.

254. Patent medicines. A doctor should never prescribe a patent medicine which he does not know the formula exactly.

298. Primipara (sic). For two weeks before the expected date of delivery give your primipara half an ounce of castor oil every other night; labor will be a dream.

The "hints," which are arranged alphabetically, have been drawn from a great variety of sources, and constitute a very grotesque collection. It is fair to add that many of them are sound and likely to be useful.

An *Epitome of Urine Examination* by the same author¹⁸ presents no novelty, but the physical characters of the excretion and various methods of qualitative and quantitative examination of normal and abnormal constituents are systematically and correctly described. The microscopic examination of urinary deposits is very cursorily alluded to, and no mention is made of bacteriological examinations.

The *General Dispenser*,¹⁹ by the same author, of which a third edition has recently been printed at Kolhapur, has been compiled for the benefit of dispensers or compounders in Indian hospitals and dispensaries, to whom it will undoubtedly be helpful. The book lays down clearly and concisely the duties of this class, gives an outline of pharmacy, dispensing, and prescribing, supplies brief notes of the action and uses of drugs and poisons, and of the treatment of excessive doses of the latter, and appends some information bearing on the duties which the dispenser may be called on to perform in the hospital when assisting the officer in charge in treating the sick and wounded, or when, as often happens, he is left in charge during the temporary absence of the latter. The work is of a practical character throughout, and is well fitted to accomplish its purpose.

Materia Mnemonics, a small pamphlet sold by William Bryce, bookseller, Edinburgh, at the price of 3d., is commended to the attention of examiners in *materia medica* as containing illustrations of many questions they ought not to ask.

The second issue of *Nisbet's Medical Directory*,²⁰ the edition for 1909, has appeared. It consists of two parts. Part I contains an alphabetical list of registered medical practitioners, giving addresses and diplomas and chief appointments held. This list has been improved by the introduction in some cases of additional initials for purposes of identification. Part II consists of a local directory, in which the names are classified under places of residence. The preface states that the present edition contains over 1,000 entries more than last year, but by attention to arrangement and printing the bulk of the book has not been increased.

In the sixth edition of his little work, *A Simple Method of Water Analysis*,²¹ in which he describes the method of analysing water by means of "soloid" reagents, Dr. J. C. THRESH gives a short guide to the interpretation of the results obtained. We agree with him that a hard-and-fast line cannot be drawn as to the amount of chlorine which should condemn a water. A very great deal of good would be done if medical officers of health would more systematically examine water supplies for chlorine and record the results. We should then be much better able to obtain a chlorine standard for particular districts. Dr. Thresh still estimates his results in parts per gallon. Has not the time arrived for the universal estimation in parts per 100,000?

²⁰ *Nisbet's Medical Directory*. London: James Nisbet and Co. (8vo, pp. 786. 7s. 6d.)

²¹ *A Simple Method of Water Analysis*. By John C. Thresh, M.D., D.Sc., D.P.H. London: J. and A. Churchill, 1908. (Fcap. 8vo, pp. 62. 2s. 6d.)

MEDICAL AND SURGICAL APPLIANCES.

A High-temperature Gas Flame.

IMPORTANT modifications in the construction of the Bunsen burner have made it possible to secure an almost completely homogeneous non-luminous gas flame, giving a considerably higher temperature than the Bunsen burner, and being also more economical in its consumption of gas. The burner, called after its inventor, the Meker, depends for its efficiency on the success with which the problem of obtaining exactly the right mixture of air has been solved. In the Bunsen burner an excess of gas was always present, and any attempt to increase the air supply beyond a low limit resulted in the formation of an explosive mixture and in the flame firing back. The Meker burner differs from the Bunsen in having a larger number of airholes at the base, in having the mixing chamber shaped like an inverted bottle, or like an injector, and in being furnished at the top with a deep nickel grid. The grid resembles a square-celled honeycomb, and is 10 mm. deep, the area of each cell being 2 mm. square. It prevents back-firing by means of the wide cooling surface it presents to the gas, for it is only with great difficulty that a flame can travel in the direction opposite to the gaseous mixture which gives rise to it, if in this inverse direction it encounters a very large cooling surface. The peculiar shape of the stem secures the perfect admixture of gas and air, and as a result of these modifications the cool inner zone of the Bunsen flame is reduced to a height of 2 mm., and the temperature of the flame is found by the thermo-couple to be practically the same at all points. Its heat is sufficiently intense to melt silver, gold or copper without the use of a blowpipe. If an air-blast is used, the temperature attained is about 1,800° C. Though the value of the burner is obvious, and though it works well in the laboratory, it is not likely that it will displace the Bunsen, for many laboratory purposes its temperature is inconveniently high, and the absence from it of the three zones of the Bunsen will be missed. For supplementing the Bunsen, however, it will be found invaluable, for it enables many operations which under ordinary circumstances have involved all the trouble of the blowpipe flame to be performed with the greatest ease. It should be added that the flame does not roar. The cost of the ordinary laboratory size is half a guinea; compressed-air burners of a similar size are made in two qualities, and cost 16s. and 28s. 6d. respectively. Specially constructed furnaces for working with the Meker burner are also supplied. The patent rights for this country and the colonies

have been acquired by the Cambridge Scientific Instrument Company, which has recently issued a list (No. 55) containing a full illustrated account of furnaces made on this principle.

Irrigation and Rectal Feeding.

We have received from Dr. H. JOSEPH CATES, Extern Midwifery Assistant, St. Bartholomew's Hospital, a description of an apparatus which he has contrived to facilitate rectal feeding, continuous saline infusion, irrigation, or any other purpose in which a regulated flow of fluid at a constant temperature is required. It consists of a metal hot-water jacket, inside which is a glass cylinder holding about a pint and a half of fluid. The stem of this passes out from the bottom of the hot-water jacket, where it is connected with a stopcock, by which the flow of the fluid can be easily regulated. To the lower extremity of the stopcock is fixed rubber tubing, at the end of which either a catheter or a needle can be attached as required. The advantages claimed for the apparatus are that it retains the heat well, is of simple construction, is easily cleaned, takes up very little room, and can be packed into a small compass. On the jacket is a strong hook on which the appliance can be hung on the bedrail, on the back of a chair, or elsewhere. It has been made for him by Messrs. Meyer and Meltzer, of Great Portland Street.

An Open Inhaler for the Administration of Ether, Chloroform, or Mixture.

Mr. HARVEY HILLIARD (Anaesthetist, Royal Dental Hospital; Assistant Instructor in Anaesthetics, London Hospital) writes: Three years ago I published¹ the description of a regulating inhaler, designed for the dosimetric administration of either ether or chloroform or of mixtures of these drugs. The chief feature of this apparatus is that the anaesthetic to be administered is placed in a reservoir, and the anaesthetist then arranges the mechanism so that a definite percentage of vapour can be delivered in the inspired air. Finding, however, that many anaesthetists prefer still to use a drop bottle, but are dissatisfied with the character of the masks in common use, particularly when it is desired to administer ether by the open method, I have designed the apparatus here figured, with a view to eliminating the inherent disadvantages of the ordinary masks. With ordinary masks it is almost impossible to attain to anything like regular, unvarying minimal dosage, since it is impossible to tell how much of a given quantity of the anaesthetic the patient inhales, and how much air gains admittance round the mask. The method is necessarily wasteful and inaccurate, and untoward results are only avoided by the skill and judgement of the anaesthetist. There can be little doubt that a certain proportion of the deaths reported from chloroform are due to the sudden variations in the dose of the anaesthetic. Anaesthetists have consequently turned from the increased dangers of chloroform to the safer administration of ether by the open method, and here, even more than in the case of chloroform, difficulties are met with. The induction of anaesthesia by this method is unnecessarily prolonged, and owing to the respiration taking place to and fro through the mask, as much of the anaesthetic is blown into the room as is inhaled by the patient, with consequent discomfort to the operator, anaesthetist, and assistants. In the apparatus shown an ordinary nitrous oxide facepiece, A, is used, and the patient breathes only through valves B and C in such a way that the inspired air passes through gauze, D, on which any desired quantity of the anaesthetic can be dropped. The gases of expiration pass out freely at the aperture, C, being prevented passing again through the gauze by the inspiratory valve, B; thus, less than half the usual quantity of the anaesthetic is required. For an adult it is necessary to use eight to sixteen layers of gauze stretched over the inspiratory opening of the inhaler, by means of the fixing ring, E. For a child less would be required. The gauze carrier, F, is detachable, and is pierced half round its collar by holes; by rotating the gauze carrier the holes are made to pass over a slot in the tube beneath them, and thus extra air can be admitted in a regular manner to mix with and dilute that passing through the gauze. To commence the administration, a drop or two only of the anaesthetic should be sprinkled on the gauze, the carrier being rotated sufficiently to uncover all the holes, so that the weakest possible vapour may be inhaled at first. As the patient becomes accustomed to the anaesthetic, the holes are occluded one by one by rotating the gauze carrier, and when they are completely closed larger quantities of the anaesthetic may be sprinkled on

the gauze, as the patient will by that time be insensitive to the strength of the vapour. Provided the facepiece is made to fit accurately, the following advantages ensue: Much less time is occupied in inducing anaesthesia with this apparatus than with any other open mask: dosage becomes more precise, since as the patient inhales the whole of the anaesthetic administered, his condition can be more accurately watched, and the anaesthetist is not subjected to the inhalation of the anaesthetic, which the patient blows from the ordinary mask with each exhalation, and his judgement, in consequence, runs much less risk of becoming dulled after prolonged administration. This point is, moreover, further ensured by the expiratory valve of the inhaler being protected by a little cowl, G, which can be turned in any position to direct the expired air away from the administrator. The detachable cap, H,

has been provided to prevent any possible excess of the anaesthetic fluid running through the apparatus, owing to too little gauze having been used, with the consequent risk of blistering the patient's face. The valves are mounted on removable collars, which can be withdrawn for cleaning. The several portions of the apparatus may be taken apart for this purpose, or for packing inside the facepiece to facilitate carriage. The method of employment for chloroform is self-evident, but for giving ether it is recommended to start with a little C.E., mixture, as this is more pleasant for the patient and shortens the induction period, and when he has become accustomed to breathing this vapour, then ether alone may be quite comfortably substituted. With this apparatus I have kept patients comfortably anaesthetized under ether for periods lasting two hours, for Wertheim's hysterectomy in the Trendelenburg position, and for the removal of the Gasserian ganglion in the sitting posture. From an experience of several hundred cases in which the apparatus has been used, I believe unpleasant after-effects are much less likely to be met with, owing to the greater precision of dosage its use makes possible. The appliance has been made for me by Messrs. Barth and Co.

MEDICINAL AND DIETETIC PREPARATIONS.

Liquid Surgical Soap.

Under the name "Sterilla," a liquid antiseptic soap has recently been put on the market by Mr. H. E. Matthews (The Mall Pharmacy, Clifton, Bristol). It is a pleasantly fragrant liquid, which we find to be free from uncombined alkali, both caustic and carbonated; when used for washing the hands it yields an abundant lather, and shows great efficiency as a detergent, while even repeated use causes no irritation of the skin beyond a slight smarting which only lasts for a few seconds. The maker has submitted for our inspection the certificates of a well-known bacteriologist, which show that for *B. typhosus*, *S. pyogenes aureus*, and *B. diphterie* this soap possesses a bactericidal power equal to that of pure carbolic acid. From its nature it cannot cause corrosion of instruments, but will distinctly help to prevent it. It can be obtained in ordinary glass bottles or in a nickel bottle for safe carriage.

ROYAL COMMISSION ON VIVISECTION.

FOURTH REPORT.

(Continued from page 396.)

WE continue our abstracts from the evidence of which the minutes are contained in the fourth report of the Royal Commission on Vivisection, issued in December, 1907.*

Evidence of W. E. Dixon, M.D.

Professor Dixon gave evidence as representative of the Therapeutical Section of the Royal Society of Medicine. Speaking about anaesthetics and narcotics, he said there was no essential difference between an anaesthetic, a narcotic, and a hypnotic. The drugs of the alcohol series which acted on the brain formed a very large group, including alcohol, chloroform, ether, paraldehyde, chloral, urethane, and many more. These drugs all acted in the same way, and their differences were determined entirely by differences in the rate of absorption and excretion. Chloroform and ether were absorbed extraordinarily rapidly. They were taken into the blood almost immediately, and when the administration was stopped they were excreted equally rapidly. On the other hand, chloral, given by the mouth, remained in the blood over a very long period. With animals, he personally preferred in many experiments to use urethane to chloroform. Perhaps chloroform was given first to get the animal under quickly; then the urethane was given either intravenously or subcutaneously, or into the peritoneal cavity, and it got into the blood and produced anaesthesia lasting from six to eight hours. The dose of urethane necessary to anaesthetize a rabbit was $1\frac{1}{2}$ gram per kilo body weight, and for a dog or a cat about 1 gram per kilo body weight. According to that reckoning, the dose to produce anaesthesia in man would be about 70 grams or 2 oz., but it was not employed for that purpose. The drugs of which he had been speaking acted on all the nerve cells in the brain in much the same way, except that in every case they paralysed the sensory nerve cells before the motor, so that there might be complete anaesthesia whilst movement could still be got; on stimulating an afferent nerve movement might be got when the sensory cells were all obliterated from the brain. Morphine acted quite differently; it only attacked the sensory nerve cells, so that if one produced complete anaesthesia from morphine, one could still get very distinct reflexes. It could be administered to man in anaesthetic doses, and quite distinct reflexes could still be obtained, although when the man subsequently recovered he had never felt anything at all. Morphine was very rarely used alone as an anaesthetic, not because it was not one, but because it left the motor cells active and the animal was reflex. The action of morphine on dogs was precisely the same as that on man. It was nearly always used for dogs—not alone, because it was necessary to cut out these movements. It was quite commonly used now for man in Germany, when it was given with some drug which also paralysed the motor cells as well as the sensory, and so in Germany, and to a limited extent in England, it was given with hyoscine (the so-called morphine-scopolamine narcosis) for operations where chloroform was deemed unsuitable. In that combination it both produced complete anaesthesia and prevented reflex movements. Two other minor points he wished to draw attention to were: First, that when surgical anaesthesia was produced the amount of anaesthetic necessary to continue that anaesthesia might be continued indefinitely by the subsequent administration of 0.2 or 0.3 per cent., or even less. The test commonly employed was the reflex test; if there was a corneal reflex one knew that the motor cells were beginning to recover their activity. The second point was the great value of giving morphine before administering chloroform. This combination produced a very perfect anaesthesia, the quantity of chloroform necessary being much smaller than would be required if no morphine had been given. Coming to curare, he said

that it was not an isolated drug; there were lots of other drugs having the same type of action. All that group paralysed the nerve cells, the brain, and every one of them paralysed the motor nerve endings, and they might all cause convulsions by acting on the spinal cord. Some members of the group had one action well defined and others another. Curare first paralysed the motor nerve endings and later the nerve cells, whilst hemlock paralysed the nerve cells and nerve endings, roughly, about the same time. Curare given alone was a complete anaesthetic if enough was given, although those conducting experiments in England assumed that curare had no action on the nerve cells, and always gave enough of some other anaesthetic to paralyse the brain completely. Claude Bernard's experiments only applied to the spinal cord; all that he showed was that the sensory cells in the spinal cord were not paralysed by curare. Nevertheless, they believed that small doses of curare would paralyse the motor nerve endings before the brain cells were paralysed, but that large doses of curare would paralyse the whole of the brain like chloroform. That meant that the animal would absolutely cease to feel pain with a large dose of curare. With a small dose it might, he thought, continue to feel pain though unable to express it by action. In reply to further questions, he said that when operating on animals he usually had a box into which he put the animal, and poured in chloroform in the case of cats and ether in the case of rabbits; to dogs he gave the chloroform by hand very slowly. Dogs very easily died of chloroform, but if one went sufficiently slowly they never died. He never killed a dog by any chance whilst administering anaesthetics to them now. Usually there were no renewal doses. The animal was placed on the table, and he gave it the urethane or chloral (usually, almost always, urethane), and then the animal was anaesthetized for very much longer than was required. He gave the urethane by injecting it into the blood. Chloral he did not use much, but he generally gave it into the peritoneal cavity. Chloral, like chloroform, depressed the heart. It produced exactly the same anaesthetic effect as urethane. There was one other point about curare which he thought extremely important, and that was that it was excreted with extraordinary rapidity; so that if one gave an animal curare it remained curarized only for a very short time. So quickly was it excreted that one could not poison a man by the mouth, because as fast as the drug got from his stomach into his blood it went out by the kidneys. He himself had taken a large dose of curare, and had never had any symptoms at all; yet if he had had a cut on his skin and let the curare get in, the curare would, he had no doubt, have paralysed or depressed his motor nerve endings. The importance of that was that if one gave an animal an anaesthetic plus curare, the curare disappeared very quickly, the anaesthesia still existing. Supposing that he injected curare into a vein, the animal remained curarized, say, for half an hour to three-quarters of an hour. If that animal had got urethane plus curare, the curare action was over in half an hour or three-quarters of an hour, while the anaesthetic action of the urethane continued for eight hours at the least. The blood pressure was just as delicate an indication of the action of chloroform as the reflexes. During the whole of his operations the blood pressure was always taken by a cannula connected with an artery to a mercurial manometer. The animal was given an anaesthetic to begin with, and it never recovered from it. He used curare very rarely. Asked what was the state of things produced by curare, which made him able to perform an operation when the animal had curare and not able to do it when it had not, the witness said, Supposing he wished to stimulate a nerve, he excited the nerve in one way or another, and he would get, if the muscles were intact, simply contraction of muscles; but if he had eliminated the muscle effect he had only got the vascular effect left. During the three or four, or perhaps five, times he had used curare he had always been absolutely satisfied that the animal had not felt pain. Speaking as to the difficulty of obtaining evidence from clinical experiments, he said he was on a committee of the British Medical Association for suggesting what drugs should go in the new *British Pharmacopoeia*, when it became necessary to find out the value of certain new silver compounds. They sent out about 300 notices to the leading ophthalmic surgeons, and

* London: Printed for His Majesty's Stationery Office, by Wyman and Sons, Limited, 109, Fetter Lane, E.C. And to be purchased, either directly or through any bookseller, from Wyman and Sons, 109, Fetter Lane, Fleet Street, E.C.; and 22, Abingdon Street, Westminster, S.W.; or Oliver and Boyd, Edinburgh; or E. Pousonby, 116, Grafton Street, Dublin. (1908.)

surgeons attached to lock hospitals, asking them what was the value of these new compounds, and the results which came in were most remarkable. It would be thought that in dealing with the action of silver compounds used for eye work, conjunctivitis, and various forms of inflammation of the eye, that if it was possible to make any definite statement from clinical observations it would be about a disease which one could actually see; yet the decisions of these expert physicians and surgeons as to the value of these new drugs were exactly divided. Some of them said, "This drug is our sheet anchor in the treatment of disease." Others regarded the same drug as quite inert and worthless. The explanation was simple. It meant that the conditions in a clinical experiment were never the same; there was no control experiment. No two men were exactly the same in every respect, except that one was being treated for a particular disease. The compounds mentioned had not been tested by animal experiment. In an experiment on an animal one had exact conditions and control. He had made experiments on perhaps eighteen to twenty dogs during the past year. There was never any difficulty in keeping a dog under an anaesthetic provided it was given slowly at first. The danger was that if one gave a dog 6 per cent of chloroform vapour it died in a minute or half a minute. If one gave it 0.1, then went to 0.2, then to 0.3, and so on, it never died. These experiments lasted perhaps two or three hours, and the animal was always killed before it recovered. He killed it generally by injecting air into a vein. He had a vein always prepared. He blew in a little air which went straight to the heart, got behind its valves, and the heart stopped beating. Proceeding, he said he gave a series of demonstrations regularly to classes. He had never seen any levity on the part of students. It was the most important part of their curriculum without any exception. Asked if there was any way by which many drugs could be standardized, except by watching their effects upon animals, he said there were five drugs—digitalis, strophanthus, squills, ergot, and cannabis indica—the chemistry of which was so little known that they could not standardize them otherwise than physiologically. The witness handed in a list of ten different ergots bought at different chemists' shops. A practitioner having to treat a woman in labour gave one of those ergots, and probably in three cases out of four it was inactive. The same applied to digitalis. This difficulty was got rid of by having the drugs—each brew—standardized. Certain wholesale chemists standardized each lot they sold. The only way by which their action could be ascertained was by experimentation on animals. The absence of accurate knowledge of the strength of drugs had led to most diverse opinions being expressed by medical practitioners as to the value of certain drugs. Cannabis indica was more usually non-active than active as bought in shops. For those drugs he had mentioned chemistry was at present quite worthless. Through their not being able to isolate the alkaloids with ease, it was very difficult to tell what was the strength of any given specimen. Asked if the composition of curare was ascertained with any certainty, he said curarine had been prepared in Germany, but one could not buy it. He did not think anything was known about its chemical composition. The tests of anaesthesia in animals that were chiefly used were the reflexes and blood pressure. As far as he knew, no attempt had been made to utilize the blood-pressure gauge for the purpose of determining the amount of anaesthesia in human beings. In the case of morphine, the test of the presence or absence of the lower reflexes was inapplicable. By a reflex action he meant an unconscious action. Most of our reflexes were unconscious. It was part of the essence of being reflex that it was an involuntary act. A reflex action might sometimes be controlled by consciousness; but consciousness was not necessarily present to a reflex action. He had taken curare himself by the mouth in a big enough dose certainly to completely curarize a dog. It had no effect of any kind at all. What he took was a very active specimen. Asked if the restriction under the Act with regard to curare should apply to the other drugs that resembled it, the witness replied that most of the other drugs paralysed the brain before they paralysed the motor nerve endings. As an example he mentioned nicotine, which paralysed the brain first. In the case of curare it happened to be the other way round; it went for the nerve endings first,

and then to the brain. That was why there was all this fuss about curare. Asked whether it was not a fact that different observers watching the same experiments on animals had drawn different conclusions, he said they did not differ on the facts. The facts remained the same. They only drew different conclusions as to how the effect was produced. There was no reason at all for supposing that a dog was less sensitive to the action of morphine than other animals of the same size and weight. He would say it was more sensitive. He had had large experience of giving morphine to dogs. In reply to further questions, he said there were no drugs with which they were acquainted which had any different action on the heart or on the kidneys of animals from that in man. The only differences which occurred were in the brain. For instance, cocaine in big doses caused convulsions. Cocaine acted on the cerebral hemisphere. In the frog there were practically no cerebral hemispheres. One could give an enormous dose of cocaine and get hardly any twitches. In the rabbit a relatively smaller dose, but still a very big dose, was wanted. In the dog, in which the cerebral hemispheres were better developed, a still smaller dose, in a monkey still smaller, and in man the smallest, was wanted. One could tell the dose of cocaine necessary to produce convulsions by weighing the cerebral hemispheres and then the body; the dose of cocaine varied in relation of these two exactly. Chemical poisons did not multiply in the blood. There was some relationship between chemical constitution and physiological action, but a small change sometimes produced a tremendous difference in action. In his opinion, urethane was the best anaesthetic for animals. Asked if it was essential to keep the provision in the Act that curare must only be administered with another anaesthetic, he said he thought that a good provision. He agreed that otherwise there would be a period of time during which there would be sensation without motion. When he took curare it was done accidentally. He did not know what was going to happen, but nothing happened at all. In Germany they had got pure crystals of curarine, but the supply of curare had given out. They were still dependent on the natives, who kept the sources of curare a secret. He regarded the statement about experiments on animals before students having a deteriorating effect on their character and humanity as absolutely ludicrous. They were every day doing more and more operations under local anaesthesia. Now they injected the local anaesthetics in quite a number of cases into the spinal theca, where it paralysed first the sensory cells, and the man lost all sensation to pain. Touch went next. Pain went first, then tactile sensation, and lastly motion. That was the sequence that always occurred. Consciousness was retained all the time. A number of experiments on the anaesthetic point were done on the investigators themselves. A man had his arm bared, and one drug was injected there, and another drug given here, and one could test it in that way. Where the animals came in mostly was as to the toxicity of these things. Anaesthesia was one property, toxicity another, irritability another. The toxicity and irritability were tested on animals. With some local anaesthetics there were considerable dangers. With cocaine one might in certain people accidentally inject the cocaine into a vein, in which case it produced a toxic action on the brain and on the heart. Secondly, one might get sufficient irritation at the seat of injection to produce objectionable symptoms. As the result of this work they had certainly determined the best local anaesthetic, and were going to recommend that it should be put in the *Pharmacopoeia*. Asked what animals were generally used for standardizing drugs, he said in the case of digitalis, strophanthus, and squills they used frogs; in the case of ergot they used cats—that was under licence alone, and the animals were anaesthetized the whole time; and with cannabis indica they used dogs. The drug was injected, the dog became intoxicated, it recovered completely, and was none the worse. In the standardization of drugs either the animal was under anaesthetics, or there was no suffering at all. Asked what modifications he would suggest in the Act, he said he would give a comprehensive licence to responsible persons, heads of laboratories; and to workers, to people who were not so responsible or who were not heads of laboratories, and so on, he would give an endorsed licence, only allowing them to do certain experiments, and only doing those

experiments under the control or supervision of someone who had had more experience in research than they had. He would abolish the certificates altogether. He would require, were such licence to be given, that a report of the whole experiment should be sent to the Home Office at the completion of the experiment. He would encourage an increase in the number of advanced students doing research work for the M.D. degree. He had never seen a painful experiment on an animal. Asked if he thought it would be well to allow the use of animals under a lethal dose of anaesthetic to enable students who were perhaps qualified medical men to gain manual dexterity in the performance of operations on human creatures, he said he thought that would be a wise provision to make for the sake of humanity. Asked if in his opinion it would be satisfactory if there were to be a freer permission of entry to witness these experiments by independent, properly-accredited witnesses in order to reassure the public, he said if the people were responsible people—that was to say, if they had had a medical education—he would not object at all. Asked if in reporting to the Home Office he would be prepared to certify that, to the best of his belief and endeavour, all the experiments which he had been carrying out had been done painlessly, he said, Yes. Asked if he would be prepared to append a certificate to that effect, he said he always did append a certificate to that effect. He thought in two or three cases he put down that they had experienced "slight pain" or something of that kind. After a subcutaneous injection of some drug an animal felt ill after it, and one had to say that it felt pain. With regard to the standardization of drugs such as digitalis, ergot, and strophanthus, he said that if a time came when they understood sufficiently of the chemistry to estimate the active bodies chemically, then the need for animal experiment would disappear. Asked if he thought that if the Act were repealed now that there would be danger of animals being unnecessarily employed for purposes of vivisection, he said he thought the medical profession would be strongly against the Act being repealed now, because any irresponsible person could make all kinds of experiments if he wished to do so at his private house. He did not agree that the Act had operated altogether antagonistically to the advance of physiology. Asked if he thought that the Home Office was likely to get assistance from the Association for the Advancement of Medicine by Research, he said, Certainly, because that body practically consisted of the highest scientific opinions in the country. Asked if he thought that the present inspection and machinery under the Act gave any real security to the public, he said, Certainly. No case of irregularity had been detected in his laboratory. Asked if he thought they might reasonably trust to the responsible vivisectioners under the Act without inspection, he said, Certainly; but at the same time there was no objection to any number of inspectors. Practically, whenever one did an experiment there were a great number of unofficial inspectors. It would make absolutely no difference to any conscientious man whether there was inspection or not. He had heard of no ill-conducted laboratory in this country.

(To be continued.)

THE BORDET-GENGOU REACTION.

SPECIFIC tests of one kind or another designed to render diagnosis more exact are multiplying apace, and it is important that the underlying principles should be grasped and we therefore propose to endeavour to give some account of the principle upon which the reaction observed by Bordet and Gengou¹ a few years ago rests, because it is probable that its more extended application will prove to be of great importance.

In discussing the matter it must be assumed that the reader is conversant with the nomenclature adopted by Ehrlich in his exposition of the "side-chain" theory, or with that adopted by the French school when dealing with the various problems connected with immunity. Should the reader, however, feel the necessity to brush up his acquaintance with the complicated terminology connected with this subject, he could not do better than turn to the

small compact monograph by Schatloff reviewed elsewhere in this issue.

No doubt, on first reading a description of the reaction described by Bordet and Gengou, it will be felt that it is most complicated, but when once its details are mastered and the various effects appreciated, it will be brought home to the reader that at last a very real gain to clinical medicine has been effected by the modern study of the reaction of the serum of the blood to foreign substances when they gain access to the blood stream.

The generic term "antigen" has been coined to indicate all these substances, bacterial bodies, animal cells, and substances such as the serums of animals and snake venom, or vegetable substances such as ricin and abrin, which though incapable of ultimate chemical analysis, seeing that their composition is profoundly changed during that proceeding, produce changes in an animal which can be demonstrated either *in vitro* or *in vivo* or in both. Ehrlich has classified the various substances formed in an animal injected with these substances—the antibodies—into three groups, according to whether they constitute (1) antitoxins, (2) precipitins and agglutinins, or (3) lysins. A lysin is a combination of complement—a substance which occurs naturally in the healthy or undisturbed animal body—and of amboceptor which, as its name implies, is a receptor having powers of combination, on the one hand with complement (complementophile affinity) and on the other with the particular kind of animal cell (cytophile affinity) which when injected into another animal gives rise to the appearance in the serum of this particular amboceptor. The particular amboceptors which are operative in the Bordet-Gengou reaction are two in number, and the reaction turns upon the fact that the complement is capable of becoming anchored to the amboceptor produced either by bacteria or by animal cells. The subject appears to become very complicated when it is added that five substances are necessary for the reaction, but they can be arranged in two groups, and it is proposed to refer only to the observations on the typhoid bacillus, although Bordet and Gengou experimented with different bacteria. An animal susceptible to its action is injected with a culture of the typhoid bacillus (the antigen). It reacts by developing as one amongst other antibodies a bacteriolyisin, that is to say, the complement naturally occurring combines with an amboceptor produced by the liberation from certain cells of the inoculated animal of receptors possessing the special character of having two affinities, one for the complement and one for the bacteria which gave rise to their liberation, in this case the typhoid bacillus. The inoculated animal is bled, and its serum is obtained after whipping the blood, by centrifugalization. The serum is then heated for half an hour at 57°C., that is, is "inactivated," or deprived of its complement. The complement being destroyed, free amboceptors are present in the serum, a measured quantity of which is mixed with some of the original antigen used—an emulsion of typhoid organisms, and a measured quantity of the serum of a normal guinea-pig added. The three constituents are then heated for about an hour in an incubator at 37°C. What takes place now is this: the amboceptor already mentioned is enabled to link itself by its cytophile affinity with the bacteria, and by its complementophile affinity with the complement contained in such abundance in the serum of a normal guinea-pig. To use a phrase so commonly associated with this reaction, the complement is "anchored to the amboceptor," and is no longer free to combine with any other amboceptor.

The ingenuity of the Bordet-Gengou reaction consists in this: that to this complement another amboceptor is offered, and the inability of the complement to become thus anchored to another amboceptor is taken as an indication of the affinity of the first-named amboceptor for the typhoid organism. If the inactive serum of a normal animal not immunized against the typhoid bacillus be placed in contact with typhoid bacilli and guinea-pig complement, no anchoring of the latter body will take place, and it will be free to enter into any other alliance of a suitable character presented to it. The remaining two elements of the five above mentioned constitute the alternative alliance. If a rabbit be immunized by injecting it, say, with the washed red corpuscles of a sheep, a hæmolytic serum is produced—that is to say, in the rabbit's serum an amboceptor is developed which by combining

¹ *Annales de l'Institut Pasteur*, 1901, vol. xv, p. 269.

with the rabbit's complement on the one hand and with washed sheep's corpuscles (the second element of this group) on the other produces such an effect that the latter are laked, the haemoglobin being transfused into the normal saline solution, with which a suspension of the sheep's corpuscles is made. Before, however, exposing the rabbit's serum to the suspension of sheep's corpuscles it is heated to $57^{\circ}\text{C}.$; in this way the rabbit's complement is destroyed and haemolytic amoebocytes left free which, though capable of combining with sheep's corpuscles, do not in such combination lake the latter, because no complement is available. To review the reaction we may now set out the five constituents in the following way:

First Group:

1. Typhoid organisms = Antigen₁ = A_1 .
2. Amoebocytes formed as a result of injecting the *Bacillus typhosus* into an animal, subsequently heating the serum to destroy complement = A_1 .
3. Complement of a normal guinea-pig = C.

If these three constituents are brought together at a suitable temperature ($37^{\circ}\text{C}.$) for one hour, they combine together in a very stable union.

$$(A_1 + A_1 + C).$$

Second Group:

4. Amoebocyte obtained as above in a haemolytic serum = A_2 .
5. Sheep's red corpuscles = Antigen₂ = A_2 .

These two at suitable temperature combine thus:

$$(A_2 + A_2).$$

If all five constituents are now placed in an incubator at $37^{\circ}\text{C}.$ for about two hours and are subsequently allowed to stand in the cold, two combinations exist thus:

$$(A_1 + A_1 + C) \text{ and } (A_2 + A_2).$$

The preparation will show sheep's corpuscles unlaked, and the mixture, though bright red, will be quite opaque. The complement C has been anchored so effectively to $A_1 + A_1$ that it is not capable of entering into the combination $A_2 + A_2$.

If the serum of an animal injected or infected with an organism quite different from the typhoid organism be prepared and substituted for A_1 , and called A_3 , the combination $A_1 + A_1 + C$ can now *not* take place, because the cytophile affinity of A_3 does not fit the antigen A_1 , and the complement C is free or unanchored. If now to these three constituents be added the above second group, $A_2 + A_2$, and the mixture be exposed to $37^{\circ}\text{C}.$ for a couple of hours, and then in the cold for several hours, the following arrangement will occur:

$$(A_1 + A_3) \text{ and } (C + A_2 + A_2)$$

but $C + A_2 + A_2$ constitutes what is known as a haemolytic system, and haemolysis will take place, the mixture of five substances now appearing as a clear red solution.

We shall not attempt to give here the many details as to the preparation of a haemolytic serum of proper strength, and as to the various dilutions of the various ingredients of the reaction, but it is hoped the principle has been made clear. This reaction has been made use of for clinical purposes by Wassermann and Bruck in conjunction with Neisser. If in the above Group 1 there be substituted for the antigen A_1 , an emulsion of a fetal syphilitic liver (containing Schaudinn's spirochaete of syphilis) and if the serum of an animal infected by typhoid or other organism be replaced by the inactivated serum of a patient known to be syphilitic, no haemolysis will occur on subsequently adding the members of Group 2, whereas if the suspect serum belongs to a patient not the subject of syphilis, haemolysis *will* occur on adding Group 2. This is now known as the Wassermann reaction or sero-diagnosis of syphilis. It has been turned to excellent account, for it has given corroborative evidence that the so-called para-syphilitic conditions—tabes and general paralysis—are of syphilitic origin, and that these maladies are expressions not of an effete infection but of a present active one.

The Bordet-Gengou reaction has already been turned to good account also in the diagnosis of infection in which the causative antigen, though certainly existent, has so far eluded detection; nor is the scope of this reaction limited to the detection of infective micro-organisms, but should be applicable to the detection of poisoning by other organic agents which are possibly responsible for much of the obscurities of clinical medicine.

A word of warning is necessary as to the limitations of this reaction, for it has been shown that a similar reaction

to that described by Wassermann can be obtained when the antigen (A_1) is not a syphilitic but a normal one; the reaction is, however, much weaker, so that the test becomes, as does the agglutination test in typhoid fever, specific truly, but only quantitatively, not qualitatively. It has further been discovered that lipid substances such as lecithin can produce the reaction; so also can sodium oleate. Despite these discoveries, the test may be accepted as reliable on the ground that, though the reaction is not due to the presence of the spirochaete alone as an antigen, it is due to the presence of a body occurring in fetal tissues which are the seat of syphilitic infection. The serum of normal individuals never gives the reaction, and 80 per cent. of syphilitic cases yield a serum which does.

We would call particular attention to the probable value in the future of the careful experimental study of the test devised by Bordet and Gengou, which, though demanding extreme care in all the manipulations, yield results readily appreciable by the naked eye. We have endeavoured to explain the principle upon which the reaction depends, and we believe that it is eminently desirable that it should be applied to other diseased conditions than those mentioned; it appears to open a new road along which many advances may be made.

COMPLIMENTARY DINNER TO DR. HERBERT JONES.

DR. HERBERT JONES was entertained at dinner at the Mitre Hotel, Hereford, on February 4th, by members of the British Medical Association and of the Society of Medical Officers of Health. Dr. EDGAR MORRIS, President of the Worcestershire and Herefordshire Branch of the British Medical Association, was in the chair, and, after the health of the King had been duly honoured, proposed the health of Dr. Herbert Jones. The dinner, he said, was held that the members might show their appreciation and esteem for Dr. Jones and to give him an assurance that he had their united sympathy. Those who knew him would understand the worry he must have experienced during the time there was a difference of opinion between himself and the county council. His medical brethren had cordially upheld him in the position which he had taken up in reference to the public health appointment. In what he had done he had acted for the good of the county at large. His brethren in the county appreciated him as a medical officer of health, knew him to be a good man, honourable and straightforward, strenuous in his work, and enjoying the full confidence of his profession, who only regretted that he was not the county medical officer of health. The President then handed to Dr. Herbert Jones a loving-cup bearing the following inscription:

Presented to

HERBERT JONES, Esq., D.P.H.CAMB.,
by Members of the British Medical Association and
the Society of Medical Officers of Health,
as an expression of their personal esteem, and in
recognition of his self-sacrificing services in the
interests of Public Health, February 4th, 1909.
Hereford.

The toast was drunk with musical honours.

DR. HERBERT JONES, in responding to the toast, thanked the President for the eloquent terms in which he had proposed his health. Most of those present had at some time or other known a convalescent patient to say that it was almost worth while being ill to get well again. He had experienced something of that sensation that evening. He desired to say nothing of his misunderstanding with the county council. It was impossible always to escape difference of opinion. He was intensely gratified that he had been asked to be their guest that evening and for the token of goodwill they had placed in his keeping. That gratification was intensified when he remembered that they intended this honour not only towards himself personally, but towards the whole public health service. On giving up general practice and starting in the public health service he had determined that his new association should in no wise divorce him from the old. However highly he might prize the exquisite example of the silversmith's art, it seemed to him that they had given him that which was far more

a prize and far more to be desired, and that was the personal support extended to him in the time of his doubts and difficulties; their action had done something that might have a more far-reaching effect in days or years to come, for their support of him would be a source of inspiration and encouragement to others. He was sure that they would feel, as he did at that time, that there was no more precious feeling a man might have than the ability to say with confidence and assurance, "I have friends who are tried and trusted and true."

The President then announced that letters of regret at their inability to be present and their personal esteem for Dr. Herbert Jones for the services rendered to the profession and to public health, had been received from the following: Sir Shirley Murphy, Dr. Holbeche (Malvern), Dr. Reid (Stafford), Dr. Symons (Bath), Dr. Manley (West Bromwich), Dr. D. S. Davies (Bristol), Dr. Davies (Swansea), Dr. Bond (Gloucester), Dr. Robertson (Birmingham), and many others.

Dr. SNELL (Coventry), in proposing the toast of "The British Medical Association," said that the privilege fell to him owing to the absence of Dr. Robertson of Birmingham, who, he regretted to say, was ill. On behalf of his own Branch and of the South-Western Branch of the Society of Medical Officers of Health, he desired to say that they were intensely gratified at being able to take part in the presentation to Dr. Herbert Jones. It was a great advantage that through the British Medical Association the services of preventive medicine and curative medicine worked hand in hand, not only for themselves, but for the public weal.

Dr. J. A. MACDONALD (Chairman of Representative Meetings of the British Medical Association), who responded, said that he was grateful for the invitation that had enabled him to do honour to his friend, Dr. Herbert Jones. The British Medical Association had the interests of its members and the public always at heart; there was no association organized like it, and its influence for good extended throughout the British Empire. He would ask them all to unite loyally in the great work of the Association, even if it meant some personal sacrifice.

Mr. LYNN THOMAS, C.B., said that he had hastened his return from Paris to join their gathering, for he felt that the occasion was unique. It gave him great pleasure to propose the toast of the Society of Medical Officers of Health, having among its number a member with such sterling qualities as "the man of the evening." It was difficult to make the public understand the point of view of medical officers of health. They always tried to carry out what was best for the public, but it took the public a long time to find that out, and it was only by having men of the stamp of Dr. Herbert Jones that they could hope to attain their ends.

Dr. J. C. McVAIL, Ex-President of the Society of Medical Officers of Health, in responding, said that it had two aims in view: (1) The protection of its members, and (2) scientific investigation of disease. Those who were carrying out these aims were often misunderstood by many who were in power and authority. He was particularly glad to be there that evening on account of its being a joint meeting to do honour to Dr. Herbert Jones, whom he had known for some years. Dr. Herbert Jones was thoroughly business-like, and did not fear to bring before the Council anything for the benefit of the public health. He thought the authorities Dr. Herbert Jones was serving should rejoice in the fact that the County Council had not deprived them of the benefit of his services. The medical officer of health and the private practitioner should co-operate cordially, and there was no better guarantee for this than that the medical officer of health should previously have been a general practitioner. Preventive medicine and curative medicine worked together for the preservation and advancement of the race, and the State should not be slow in recognizing the fact, and adequately remunerating those who work in its interests.

The late Sir Arthur Vernon Macan, of Dublin, the distinguished obstetrician, left personal estate in the United Kingdom valued at £25,924. He bequeathed his midwifery instruments and objects for the teaching of midwifery to Trinity College, Dublin, and his French and German medical books and his English books on midwifery to the Royal College of Physicians, Ireland.

THE STATE REGISTRATION OF NURSES

THE HISTORY, PROGRESS, AND PRESENT POSITION OF THE MOVEMENT.

EARLY HISTORY.

THE question of establishing an official register of nurses, recently the subject of correspondence in this JOURNAL, has a long history.

There is a common impression that nursing as a distinct occupation for lay women practically came into existence with the creation of the Kaiserswerth Deaconesses Institution in Germany and the noble work of Miss Nightingale in this country, but this is not quite true. Doubtless, in private life, the sick depended in earlier times mainly on the care of their personal friends, with such miscellaneous assistance as could be secured; but, so far as ward work is concerned, the extracts from the account of St. Bartholomew's Hospital published in the JOURNAL last year, show clearly that not only must lay women have taken to nursing as a regular occupation, but that in many respects the question of hospital nursing as it then was had been well thought out, and that in broad outline the rules laid down were in keeping with those of the present time.

Those thus engaged were no doubt of a class inferior to that which for the most part fills the nursing ranks to-day, and of course, too, from a modern standpoint they must have been very ignorant. As regards those moral qualities which help to make a good nurse, it is difficult to believe that either in the early Victorian age or at any other period were nurses of the gruesome type familiar to readers of *Martin Chuzzlewit* the rule rather than the exception. There must, in short, have been excellent if ignorant nurses long before Miss Nightingale came on the scene.

In any case it is certain that in the year 1634—that is to say, early in the reign of Charles I—there was a sufficient number of women working as nurses in London for a movement much of the kind now in progress to be going on, and this, as now, was presumably instigated partly from a desire to improve the position of nurses, partly in the interest of the public. It was headed by an eminent physician of the time, Dr. Peter Chamberlen, and had it been successful would have resulted in all nurses being placed under the aegis and control of the Royal College of Physicians. It was not successful, but that it took place at all shows that the idea of regulating the education of nurses, of giving them a definite official status, and of submitting them to control—in short, of nurses' registration—is really quite ancient, though to most of us it seems so modern.

In its present form the movement began almost as soon as systematic training of nurses had become at all general. Agitated quietly in the early Eighties, it practically first reached the surface through the action of the Hospitals Association. At a meeting of this body in October, 1887, the late Sir Andrew Clark brought the subject forward, stating that one of the purposes of the association was to obtain registration of nurses; their work, he said, formed an important part of hospital administration, and their registration was necessary for the security of those engaged in nursing who were competent, of good character, and of proved loyalty in the performance of their duties.¹ These attributes, he added, were not always to be found among nurses who offered themselves for employment, and the ability of a nurse to perform her duties could only be established by examination and certification.

This meeting was entirely favourable to the idea and resolved to give effect to it. The only immediate result, however, was the prompt formation of another body which, though equally favourable to the idea of registration, did not approve of the constitution of the Hospitals Association and its methods. This body was christened the British Nurses' Association, which originated two months after the date of the meeting of the Hospitals Association in question, and was at once joined by the matrons of a large number of the more important hospitals in London and the provinces.

For a time these two bodies, though in a way antagonistic to one another, seem to have been practically identical in their aims. The more active of the two was

¹ BRITISH MEDICAL JOURNAL, 1887, vol. ii, p. 851.

the British Nurses' Association, and in a few months it seems to have had at its back most of the leading medical men in London. The result was that early in 1888² a meeting of medical men was held in St. George's Hall, at which the late Sir William Savory, then President of the Royal College of Surgeons, was in the chair, being supported by Sir Henry Acland, Dr. (afterwards Sir Richard) Quain, Lord (then Sir Joseph) Lister, Sir Dyce Duckworth, Sir Douglas Powell, Sir Joseph Fayer, and other prominent medical men. The subject was debated at considerable length, and the meeting ended in unanimous adoption of the following resolution:

This meeting desires to express its cordial sympathy with the British Nurses' Association, and pledges itself to support that Association by every means in its power, and urges all nurses in the United Kingdom who are eligible for membership to join the Association for the sake of promoting the advancement of that profession.

In the course of the same year, however, there seems to have been a change of view on the part of the Hospitals Association, and by the beginning of 1889 a counter current had set in. The result was that a manifesto against nurses' registration was published,³ bearing the signatures of persons connected with a large proportion of the London hospitals.

This manifesto, which was met by a Mansion House meeting in favour of nurses' registration, does not seem to have proved very effective, however, for at its autumn session in the same year the General Medical Council considered the question at issue and passed the following resolution:

In the opinion of the Council it would be much to the advantage of the public, and particularly would it be of much convenience to the practitioners, that facilities useable under proper guarantees in all parts of the United Kingdom should be given by Act of Parliament or otherwise for the authoritative certification of competent trained nurses, who when certified should be subject to common rules of discipline.

The next event to be noted was the granting to the British Nurses' Association of a Royal Charter, its importance lying in the fact that the approved preamble contained a statement to the effect that the maintenance of a list of nurses showing what training they had received and when and where in each case it had been obtained was of importance to the public.

Next came the foundation of the Matrons' Council of Great Britain and Ireland in 1894, the second of its stated objects being "to bring about a uniform system of education, examination, certification, and state registration for nurses in British hospitals."

PROGRESS.

Up to this time the British Medical Association had not expressed any view favourable or unfavourable to the movement. In 1895, however, when the annual meeting was held in London, the question was brought forward and the following resolution unanimously adopted:

In the opinion of this meeting it is expedient that an Act of Parliament should as soon as possible be passed for the registration of medical, surgical and obstetric nurses, and the Council of the Association are therefore requested to consider the matter and to take such measures as may seem to them advisable to obtain such legislation.

In due course this resolution was referred to the Parliamentary Bills Committee, the body at that time filling for the Association the functions now exercised by the Medico-Political and some other committees. The question having been duly discussed this committee decided to arrange for a conference between itself and various institutions likely to be interested in the matter. This took place early in 1896⁴ and resulted in the proposal from the chair of the following resolution:

A legal system for the registration of nurses is inexpedient in principle, injurious to the best interests of nurses, and of doubtful public benefit.

In voting on this motion it was asked that only those representative of nursing institutions should take part, and it was adopted by 6 votes to 5. Curiously enough, the decisive vote, that which turned the scale against registration on this occasion, came from the honorary secretary of the body especially founded to secure registration—namely, the Royal British Nurses' Association.

It should be added that, from the record of the proceedings, it would appear that many of those present felt that prosecution of a scheme for general registration of all nurses might interfere with another movement then in the course of active development—namely, that which some five years later resulted in the passage of the Midwives Act.

After this set-back, there was a kind of pause in the movement so far as its public discussion by representative bodies was concerned, but it continued to progress on the American continent and other countries, and in England renewed activity was heralded by the foundation of the Society for the State Registration of Trained Nurses. The object of this society was, of course, as its name connotes, "to obtain an Act of Parliament providing for the legal registration of trained nurses."

So far as actual attempts at legislation go, the subject, however, did not reach the surface until 1904, in which year two bills were introduced into the House of Commons. One of these was promoted on behalf of the society just mentioned, and the other—providing for the registration both of nurses and of nursing homes—by the Royal British Nurses' Association.

A manifesto against these bills was promptly prepared and was as promptly answered by the other side, copies of both documents being published in this JOURNAL.⁵ The net outcome of the matter was that the House of Commons decided to appoint a Select Committee to consider the issues involved. This committee held seven meetings, and the session being then at an end asked to be reappointed. Meantime it published a Blue Book containing minutes of the evidence received.

In the same year the question was considered at a meeting of the Royal College of Surgeons in Ireland, and ended in the adoption, with two dissentients, of the following resolution:

It is essential that nurses throughout the United Kingdom should be sufficiently educated for the performance of the responsible duties entrusted to them. That a minimum standard of education, and under rules of discipline, could be secured only by an Act of Parliament. That as a preliminary to such legislation it is desirable that a Select Committee of the House of Commons should be appointed at an early date to inquire into the whole nursing system.

In this same year the Medico-Political Committee of the British Medical Association, which was now in full work, likewise considered the subject and prepared a memorandum,⁶ drawing attention to the principal provisions of the two bills. It considered that the board proposed to be established under either bill was unduly large, and that attempts to represent so many bodies and institutions should be abandoned. The medical profession, it thought, would be adequately represented by three medical practitioners, one nominated by the Crown, one by the General Medical Council, and one by the British Medical Association. The opinion was expressed that the earliest age at which nurses should be registered was 24, training to commence after the age of 21; and, with regard to penal clauses, that no penalties should apply to a nurse who acted gratuitously, or to a nurse who nursed for hire but did not claim to be a registered nurse. This memorandum was circulated among the Divisions, but does not appear to have attracted much attention.

At the Annual Representative Meeting at Oxford in the same year,⁷ it was formally moved:

This meeting approves of the principle of the registration of nurses.

This resolution was carried by a large majority, and it was agreed that it should be brought to the notice of the Select Committee of the House of Commons which was then sitting.

The following year, 1905, was one of great activity. Application was made to the Board of Trade for a licence of incorporation to a society named the Society for promoting the Higher Education and Training of Nurses, all the applicants being laymen of influence. They held that as legislation for the State registration of nurses could not be looked for at any early date, something should be done to improve the organization of nursing. To this end

⁸ BRITISH MEDICAL JOURNAL, vol. i, 1905, p. 254.

they formed themselves into an association, whose stated objects as stated in the articles were:

1. To promote the higher education and training of nurses.
2. To promote unity of curriculum in the training of persons intended for the nursing profession.
3. To recognize approved training schools.
4. To grant certificates of proficiency in nursing to persons who have passed prescribed examinations after training, and to grant certificates of training and proficiency in nursing to persons who have been trained in recognized schools, and have passed prescribed examinations, provided that the society shall not grant titles or diplomas.

The succeeding articles dealt with the curriculum to be demanded, registration of those certified, removals from the Register, and the maintenance of examination and lecture halls properly equipped for lectures and demonstrations.

This application at once met with strong opposition, the Council of the British Medical Association appointing a subcommittee to watch the matter, and various associations representing nursing took corresponding measures. Eventually, evidence against the proposed licence was formally given before the Board of Trade by witnesses who included⁹ the Chairman of the Representative Meeting, and the Chairman and two members of Council of the British Medical Association, and by representatives of the Central Hospitals Council and of the Royal College of Surgeons of Ireland. The view expressed was that the time had long passed when private persons should be allowed to group themselves together to carry out State duties. The medical profession was prepared to accept a system of registration which would supply it with the means of recognizing who was a properly-trained nurse, but it would only accept State registration and not pseudo-registration by a private body, more especially one which consisted of laymen only.

When Parliament met, two bills with registration of nurses as their object were again introduced in the House of Commons, and the Select Committee of the previous year was reappointed. This body heard a great deal more evidence, including that which was tendered in favour of registration on behalf of the British Medical Association by the Chairman of the Representative Meeting.¹⁰

The publication of the report of the Select Committee almost coincided with a further consideration of the topic by the Annual Representative Meeting at Leicester in the same year. On this occasion it was proposed that the resolution passed in the previous year at Oxford should be rescinded, and that the question of the State registration of nurses should be referred to the Divisions,¹¹ but after some discussion the motion was amended so as to read:

That the subject of State registration of nurses should be referred to Divisions for their consideration.

The principal recommendations in the report of the Select Committee¹² were that

A register should be kept by a central body appointed by the State, consisting of representatives of the medical profession, of training schools for nurses, of the public, and of matrons and nurses. This body should decide what persons should be admitted to the Register and what evidence of training should be required.

Unregistered persons should not be prohibited from following the occupation of a nurse provided they did not give themselves out as registered nurses.

Four years after the passage of any Act such as that contemplated, the central body ought to submit to the Privy Council a report on the advisability of instituting a separate register for nurses whose training was of a lower standard than that laid down for ordinary registered nurses.

There should also be a separate register for registered asylums nurses, the persons admitted being nurses who had served not less than three years in not more than two asylums and had received the certificate of the Medico-Psychological Association.

All homes purporting to receive patients for profit, or to supply nurses to the public, should work under a licence, and a condition of such licence should be that when nurses were sent out or employed at a nursing home who were not registered nurses, the fact should be definitely stated.

In the following year, 1906, the movement followed much the same course as in the previous year. Two bills were again introduced in the House of Commons and deputations for and against these measures were received by the Lord President of Council. Meantime the Medico-

Political Committee of the British Medical Association, in accordance with the resolution of the Representative Meeting the previous year, submitted the subject of nurses' registration to the Divisions in the following form:

1. Does the Division approve in general of the method of registration for nurses proposed by the Select Committee of the House of Commons?
2. Does the Division approve of the separate register of midwifery nurses?

At the same time the committee caused to be published¹³ a memorandum in which the main recommendations of the Select Committee of the House of Commons were summarized. A certain number of replies from various Divisions were received, and the whole question was again discussed at the Representative Meeting which was held that year in London.¹⁴ The discussion ended in the adoption, by 90 votes to 3, of the following resolution:

This meeting approves of the recommendation of the Parliamentary Select Committee that there should be a State registration of nurses, and is of opinion that on any central council or board appointed the medical profession and the nursing profession should be adequately and directly represented.

To this resolution it was proposed and agreed, with one dissentient, to add the following words as a rider:

The representation of the medical profession on the Central Nursing Board should be at least one-half of the number of the members of that body.

PRESENT POSITION.

The following year, 1907, was one of comparative inaction, though two bills were again introduced in the House of Commons. Last year, 1908, the same bills were again introduced into the House of Commons, while a third bill dealing with the same general subject was introduced in the House of Lords on behalf of the Central Hospitals Council. This bill, to quote from a note on the subject published in this JOURNAL at the time,

ignored the principle which the Legislature has followed in regard to registration of medical men, solicitors, dentists, pharmacists and midwives, and its effect would have been to place the control of the public safeguard for the efficiency of nurses entirely in the hands of hospitals and other training institutions, the governing bodies of which are selected for their administrative capacity in hospital management and not with any regard to their capacity for directing the training of nurses.

As will be gathered from this passage, the bill was rejected. It was formally opposed on behalf of the British Medical Association, and received short shrift.

Subsequently both the bills introduced in the House of Commons were allowed to drop, but immediately afterwards one of these bills, that which the Council of the British Medical Association on the advice of the Medico-Political Committee was disposed to favour, was introduced in a modified form into the House of Lords. Here it was amended and reamended on multiple occasions, but finally passed the third reading by a large majority and was remitted to the House of Commons, by whom it was ordered to be printed on November 18th. Ireland is included in its scope. At first there was some doubt whether this would be the case, as the Local Government Board in Ireland objected. Its objections were withdrawn, however, owing to the urgent desire for Ireland to be included in the bill, which was expressed at various public meetings in Ireland.

In the final moulding of this bill the Medico-Political Committee of the British Medical Association had, it is understood, considerable say. The more important provisions of the bill are as follows:

The establishment of a Council of 16 persons; 3 being appointed by the Privy Council (1 at least of these being a woman); 1 medical man by the Local Government Board; 1 medical man by the General Medical Council; 3 medical men by the British Medical Association (1 to be resident in England, 1 in Scotland, and 1 in Ireland); 1 medical man by the Medico-Psychological Association; 7 direct representatives of registered nurses (4 nurses to be elected by those having addresses in England or Wales; 1 by those in Scotland, 1 by those in Ireland, and 1 (who must be a past or present matron of a public hospital for the insane) by nurses' in the Nurses' Mental Register).

The election, however, of these seven direct representatives will not take place until the Lord President

⁹ BRITISH MEDICAL JOURNAL, 1905, vol. i, p. 1062.

¹⁰ *Ibid.*, p. 1186.

¹¹ SUPPLEMENT, BRITISH MEDICAL JOURNAL, vol. ii, 1905, p. 140.

¹² *Ibid.*, p. 158.

¹³ SUPPLEMENT, BRITISH MEDICAL JOURNAL, 1906, vol. i, p. 78.

¹⁴ *Ibid.*, vol. ii, p. 121.

of Council certifies that the register of nurses is sufficiently advanced to admit of an election by registered nurses. Meantime their places will be filled as follows:

Two past or present matrons selected by the Matrons' Council of Great Britain and Ireland: 1 past or present matron of a public asylum for the insane, to be appointed by the Asylum Workers' Association; 1 nurse by the Society for the State Registration of Trained Nurses; 1 nurse by the Queen Victoria's Jubilee Institute for Nurses; 1 nurse by the Royal British Nurses' Association; 1 nurse by the Irish Nurses' Association.

In other words, the Nurses' Council is to be formed under this bill of 6 registered medical men, of 7 direct representatives of nurses, and of 3 persons who need not necessarily belong either to the one class or the other.

The councillors are to hold office for five years, and, besides maintaining a *Nurses' Register*,

1. To frame rules (A) regulating their own proceedings; (B) regulating the issue of certificates of registration and the conditions of admission to the register of nurses; (C) regulating the course of training and the conduct of examinations and the remuneration of the examiners; (D) regulating the admission to the register of persons already in practice as trained nurses at the commencement of this Act; (E) regulating, supervising, and restricting within due limits the practice of registered nurses; (F) defining the particulars required to be given in any notice under this Act.

2. To appoint examiners and inspectors.

3. To decide upon the places where and the times when the examination shall be held.

4. To issue and cancel certificates of registration.

5. To publish annually a register of nurses containing the names, addresses, and qualifications of nurses who have been duly registered under this Act.

6. To decide upon the suspension or removal from the register of the name of any nurse for any breach of the rules and regulations from time to time laid down under this Act by the Council, or for conduct disgraceful in a professional respect, and also to decide upon the restoration to the register of the name of any nurse so suspended or removed.

7. To take proceedings against persons guilty of offences under this Act.

Any person within three years from the date at which the Act comes into force can be registered on showing that he or she is at least 21 years old, of good character, and either—

- (1) holds a certificate of training for such period as may be prescribed by the rules framed under the provisions of the Act from a hospital or from hospitals approved by the Council, or from an institution or institutions which the Local Government Board recommend, and certify to be wholly or partly maintained out of rates; or (2) holds a certificate of similar training as a nurse authorized by the Local Commissioners of the Admiralty for the sick berth staff of the Royal Navy, or as a nurse authorized by the Army Council for soldiers of the Royal Army Medical Corps; or (3) holds a certificate from the Local Government Board for Ireland, that she possesses the qualifications prescribed for the purposes of section fifty-eight of the Local Government (Ireland) Act, 1898; or (4) produces evidence satisfactory to the Council of training prescribed by the rules framed under the provisions of this Act, and has in addition been for at least three years in bona fide practice as a nurse, or employed as a nurse in a naval or military hospital.

After the expiration of three years certification can only be obtained by satisfying the Council that the applicant has been trained in an approved hospital or hospitals, or in an institution recommended by the Local Government Board, or in the navy or army, and by passing such examination as the Council may prescribe, or producing a certificate of having passed an examination which the Council will accept in lieu thereof. The register is to be kept in two parts, one being a general register, and the other a register of asylum-trained nurses. The persons admitted to the latter must hold the certificate of the Medico-Psychological Association, or its equivalent granted under conditions approved by the Council, or must have qualified as mental attendants in the Royal Army Medical Corps.

Provision is made for a fee of 3 guineas for examination, of 2 guineas for registration, and for a payment of 2s. 6d. annually by all registered nurses.

No penalty is imposed on persons following the occupation of nursing unless they pretend they are registered nurses. Training institutions not accorded recognition by the Board may appeal to the Privy Council, and nurses removed from the *Register* may appeal within three months from the date thereof and to the High Court of Justice. All rules drawn up by the Council must be approved by the Privy Council.

Finally the Council may, on representation made within four years from the commencement of the Act, be given power to institute a register of nurses, to be called a register of "associate" nurses, having a lower standard of training than that required for registered nurses, but such nurses would not be entitled to use the word "registered" except in connexion with "associate," and would have no voice in elections of direct representatives.

Compared with its predecessors, this bill, which of course still has to run the gauntlet of the House of Commons, may be regarded as a compromise, as an attempt to meet the views of various conflicting parties. It accords to the medical profession a considerably higher proportion of representatives than the Medico-Political Committee in its original memorandum asked for, three of the six medical representatives being appointed by the British Medical Association itself. It secures the interest of asylum workers by placing one nomination in the hands of the Medico-Psychological Association, and by also giving nurses on the Mental Register a direct representative. It secures alike to private and official training schools a continuance of their present powers.

It does not attempt to interfere with the practice of nursing by women who have undergone no training or only part training, but puts a premium on efficient training by conferring on persons deemed efficiently trained a definite status and a title which cannot be used by other people. On the other hand, those admitted to the status of registered nurse will be submitted to discipline and control, having to obey rules laid down for their conduct, or in default risk the erasure of their names from the *Register*. These rules before they take effect will have to be approved by the Privy Council, and at the last session of the General Medical Council it was resolved to suggest to Government that before they were approved by the Privy Council they should be submitted to the General Medical Council, as in the case of the rules of the Central Midwives Board.

Finally, as regards the history of the movement, there is one curious fact. From the beginning the arguments respectively used by the opponents and advocates of the registration of nurses have scarcely varied. Everything that has been said for or against can be found in effect set forth in issues of the *BRITISH MEDICAL JOURNAL* published twenty years or so ago.

MEDICAL PROTECTION.

We are requested to state that the National General Insurance Company, Limited, is now issuing policies of insurance to members of the London and Counties Medical Protection Society, Limited, on the following terms:

1. The London and Counties Medical Protection Society, Limited, will, as heretofore, undertake the defence of members in actions brought against them, where, in the opinion of the Council, such actions are proper cases to be defended.

2. In the event of the defence being unsuccessful, and of judgement being given against the member sued, the National General Insurance Company, Limited, will pay the amount of damages awarded, together with the plaintiff's taxed costs, not exceeding in the whole £2,000 in any one year for any one member. The effect of this will be that in all cases where the Council undertakes the defence, the member will be fully protected (subject to the limit mentioned), whatever the ultimate result of the case may be.

3. The premium to be charged by the National General Insurance Company, Limited, for the indemnity has been arranged at 10s. per member per annum, with the addition of 5s. in respect of each qualified assistant and 2s. 6d. for each dispenser employed.

We are informed that large numbers of the members of the London and Counties Medical Protection Society have already taken out the above policies. The insurance is available only to members of the London and Counties Medical Protection Society, and the benefits of such insurance can be obtained only when actions are defended by the society at its own cost. As the Council of the London and Counties Medical Protection Society does not knowingly defend actions in which its members are in the wrong, this complete indemnity will not benefit any

medical or dental practitioner who is careless or culpable in dealing with his patients. Full particulars of these policies can be obtained either from the National General Insurance Company, King's House, King Street, London, E.C., or from Dr. Hugh Woods, 31, Craven Street, Strand, London, W.C.

Nova et Vetera.

AN OLD PHYSICIAN'S CLASSICAL EDUCATION.

BASED ON MATTHEW BAILLIE'S UNPUBLISHED PAPERS.

It may be conjectured that the old physicians aimed at the acquisition of classical learning on the same grounds as the other well-bred men of their times, and that they studied the ancients not so much for learning's sake as because not to be versed in Latin and Greek was to lose caste among gentlemen.

John Hunter, a rugged revolutionary, despised this attitude of mind as heartily as might any modern. "They wanted to make an old woman of me, or that I should stuff Latin and Greek at the university," he said to Sir Anthony Carlisle, referring to his phenomenally short sojourn at St. Mary Hall, Oxford, in June and July, 1755; "but these schemes I cracked like so many vermin as they came before me" he added, somewhat naively, suiting action to word and "cracking" an imaginary insect upon the table in front of him. The anecdote gives us an unconventional, a vivid idea of Hunter and of eighteenth century habits south as well as north of the Tweed. But we need not particularize.

John Hunter of course had been sent to the English University much too late in life, for he was born in 1728, and was 27 and an able surgeon, as well as *viveur*, when set down to a task usually undertaken seven or eight years earlier. Why he was sent to Oxford we do not know, or whether he sent himself. Most probably he went at the suggestion of his brother William, who, a scholar himself, feared that John would suffer in his profession through lack of the ordinary genteel outfit of quotations from the Latin and Greek authors, or—and this was perhaps most important—would continue hampered in his studies by inability to read Latin, which was at that time the international language of science.

It would be interesting to know what Hunter saw and heard at a clerical and leisurely university, where Jacobitism interested a few vehement spirits overtly, and learning, though dear to many, would seem to have been in permanent hiding. His Oxford life seems to have hardened his feeling towards literature into life-long dislike. In 1775 he writes to James Baillie, his minister brother-in-law:

I am not anxious about my children but in their doing well in this world. I would rather make them feel one moral virtue than read libraries of all the dead and living languages. You know I am no *scholar*, therefore do not feel the beauty of language when I do not see the use of it.

The letter is characteristic of John Hunter, and of a type of utilitarian semicivility very aggressive to-day. James Baillie, a man of culture himself, afterwards became a Glasgow professor, and was the father of the famous authoress, Joanna Baillie. His son Matthew he was careful to educate well, sending him first to the Grammar School of Hamilton and then to the University of Glasgow. Later the opinion of William, not of plain-spoken John Hunter, was taken in matters educational by members of the Baillie family. It was by the advice of William Hunter that Matthew Baillie chose medicine as a profession, and by the same advice, we must suppose, that, after his father's death, he was entered at Balliol College, Oxford, in 1779. From Oxford he wrote some fourteen letters to his uncle and patron, Dr. William Hunter, in whose London house he lived, and from whose instructions he profited during vacations. These letters, which, with the exception of the first, have not apparently been published, are preserved among her family papers by Miss Hunter Baillie, granddaughter of Dr. Matthew Baillie, to whom the writer desires to tender his best thanks for leave to reprint their more interesting passages.

In a letter dated March 13th, 1779, Matthew writes to his uncle:

Dr. Sir.—I would wish to receive your advice as my Parent about that plan of study you would wish me to pursue at Oxford. I would wish likewise to talk over with you the manners of the Place, that I may not go unguarded or unprepared to it. I am told that there is a great deal of dissipation in it. I would therefore wish your warmest advice with regard to my Behaviour.

It would be unfair to infer from this last passage that young Baillie was a prig. On the contrary, he was a lad of high character, deeply impressed with a sense of obligation to William Hunter, who, as his guardian, had come to the rescue of his mother, sisters, and himself when the death of Professor Baillie had left them in straitened circumstances. It is interesting to note that, at about this date, the famous Professor Thomas Reid, the metaphysician, who had taught young Baillie logic in Glasgow, writes to William Hunter in praise of the lad's sense and integrity, and hopes they will stand him in good stead in Oxford, where application is not easy.

Continuing his letter, young Baillie refers to the study of languages. As to Latin, Greek and French:

I would wish to make myself as complete in these as possible.

Writing from Oxford on April 10th, 1779, he says:

Upon Thursday last I entered a Student of Balliol College and underwent all these Forms which were necessary at my entrance. I found no room ready for me at Balliol, but am living at present in another Gentleman's room who has gone to London.

In the letters which follow very little more is said of college life: indeed, they are the reports of a student to his master, but as such they contain a marvellous record of hard work.

Speaking of translations on May 5th, a few days after entering at Balliol, Baillie writes:

I now send you part of what I have done, transcribed from my little books, exactly in the order in which it lies there. I have not picked out one passage and omitted another, according as I thought them good or bad, but you have it exactly in its proper order. When it is sent you I beg your opinion about it whenever you have time to write, but at the same time would wish you would shew it to no person. It will only bear the examination of those who are willing to make every allowance.

Then follows a note which implies that he left Glasgow with a good knowledge of Homer. He said:

Since I came to Oxford I have likewise read eleven books of the *Odyssey* with a more critical eye than ever I did any Greek before.

He translates a passage of Caesar into English and retranslates into Latin without reference to the text. The translation accompanies the letter, and has been sparsely, and perhaps hesitatingly, corrected in the great William Hunter's handwriting. Several other translations occur in this correspondence.

In the same letter Baillie writes conscientiously about his expenditure:

If you think it proper I will send you now and then a general scheme of my expense, and if there is any article which can be cut off with decency I beg you would retrench it. I would wish to live at the least expense it was possible, but at the same time not appear mean.

He attends his tutor Prosser's lectures, and at a later date thanks his uncle for politeness shown by him to this don and to Dr. Lee. He also makes mention of Professor Whyte, Laudian Professor of Arabic, and of a Dr. Leigh. The mention of a professor of Oriental languages suggests that his studies went beyond Latin and Greek.

On October 14th, 1779, we find him writing to his uncle:
